

30V Input, 1A Output, High-Efficiency, Integrated Synchronous Switch Step-Down Regulator

Features:

- · Up to 95% Efficiency
- · Input Voltage Range: 4.4V to 30V
- · 1A Output Current Capability
- Output Voltage Range: 2.0V to 24V
- Integrated N-Channel Low and High-Side Switches:
 - 170 m Ω , Low Side
 - 300 m Ω , High Side
- · Stable Reference Voltage: 0.8V
- Automatic Pulse Frequency Modulation/Pulse-Width Modulation (PFM/PWM) Operation (MCP16311):
 - PFM Operation Disabled (MCP16312)
 - PWM Operation: 500 kHz
- Low Device Shutdown Current: 3 μA typical
- · Low Device Quiescent Current:
 - 44 μA (non-switching, PFM Mode)
- · Internal Compensation
- Internal Soft-Start: 300 µs (EN low to high)
- · Peak Current Mode Control
- Cycle-by-Cycle Peak Current Limit
- · Undervoltage Lockout (UVLO):
 - 4.1V typical to start
 - 3.6V typical to stop
- · Overtemperature Protection
- · Thermal Shutdown:
 - +150°C
 - +25°C Hysteresis

Applications:

- PIC[®]/dsPIC[®] Microcontroller Bias Supply
- 24V Industrial Input DC-DC Conversion
- General Purpose DC-DC Conversion
- · Local Point of Load Regulation
- · Automotive Battery Regulation
- · Set-Top Boxes
- · Cable Modems
- Wall Transformer Regulation
- · Laptop Computers
- · Networking Systems
- · AC-DC Digital Control Bias
- · Distributed Power Supplies

General Description:

The MCP16311/2 is a compact, high-efficiency, fixed frequency, synchronous step-down DC-DC converter in a 8-pin MSOP, or 2 x 3 TDFN package that operates from input voltage sources up to 30V. Integrated features include a high-side and a low-side switch, fixed frequency Peak Current Mode Control, internal compensation, peak-current limit and overtemperature protection. The MCP16311/2 provides all the active functions for local DC-DC conversion, with fast transient response and accurate regulation.

High-converter efficiency is achieved by integrating the current-limited, low-resistance, high-speed low-side and high-side switches, and associated drive circuitry. The MCP16311 is capable of running in PWM/PFM mode. It switches in PFM mode for light load conditions and for large buck conversion ratios. This results in a higher efficiency over all load ranges. The MCP16312 is running in PWM mode-only, and is recommended for noise-sensitive applications.

The MCP16311/2 can supply up to 1A of continuous current while regulating the output voltage from 2V to 12V. An integrated, high-performance peak current mode architecture keeps the output voltage tightly regulated, even during input voltage steps and output current transient conditions, that are common in power systems.

The EN input is used to turn the device on and off. While off, only a few micro amps of current are consumed from the input.

Output voltage is set with an external resistor divider. The MCP16311/2 is offered in a small MSOP-8 and 2 x 3 TDFN surface mount packages.

3.0 PIN DESCRIPTIONS

The descriptions of the pins are listed in Table 3-1.

TABLE 3-1: PIN FUNCTION TABLE

MCP16311/2 2 x 3 TDFN	MCP16311/2 MSOP	Symbol	Description	
1	1	V_{FB}	Output Voltage Feedback pin. Connect V_{FB} to an external resistor divider to set the output voltage.	
2	2	V _{CC}	Internal Regulator Output pin. Bypass Capacitor is required on this pin to provide high peak current for gate drive.	
3	3	EN	Enable pin. Logic high enables the operation. Do not allow this pin to float.	
4	4	V _{IN}	Input Supply Voltage pin for power and internal biasing.	
5	5	P_{GND}	Power Ground pin	
6	6	SW	Output Switch Node pin, connects to the inductor and the bootstrap capacitor.	
7	7	BOOST	Boost Voltage pin that supplies the driver used to control the high- side NMOS switch. A bootstrap capacitor is connected between the BOOST and SW pins.	
8	8	A _{GND}	Signal Ground pin	
9	_	EP	Exposed Thermal Pad	

3.1 Feedback Voltage Pin (V_{FB})

The V_{FB} pin is used to provide output voltage regulation by using a resistor divider. The V_{FB} voltage will be 0.800V typical with the output voltage in regulation.

3.2 Internal Bias Pin (V_{CC})

The V_{CC} internal bias is derived from the input voltage $V_{IN}.\ V_{CC}$ is set to 5.0V typical. The V_{CC} is used to provide a stable low bias voltage for the upper and lower gate drive circuits. This output should be decoupled to A_{GND} with a 1 μF capacitor, X7R. This capacitor should be connected as close as possible to the V_{CC} and A_{GND} pin.

3.3 Enable Pin (EN)

The EN pin is a logic-level input used to enable or disable the device and lower the quiescent current while disabled. A logic high (> 1.3V) will enable the regulator output. A logic low (< 1V) will ensure that the regulator is disabled.

3.4 Power Supply Input Voltage Pin (V_{IN})

Connect the input voltage source to V_{IN} . The input source should be decoupled to GND with a 4.7 μ F - 20 μ F capacitor, depending on the impedance of the source and output current. The input capacitor provides current for the switch node and a stable voltage source for the internal device power. This capacitor should be connected as close as possible to the V_{IN} and GND pins. For light-load applications, a 2.2 μ F X7R or X5R ceramic capacitor can be used.

3.5 Analog Ground Pin (A_{GND})

This ground is used by most internal circuits, such as the analog reference, control loop and other circuits.

3.6 Power Ground Pin (P_{GND})

This is a separate ground connection used for the lowside synchronous switch. The length of the trace from the input cap return, output cap return and GND pin should be made as short as possible to minimize the noise in the system. The power ground and the analog ground should be connected in a single point.

3.7 Switch Node Pin (SW)

The switch node pin is connected internally to the lowside and high-side switch, and externally to the SW node, consisting of the inductor and boost capacitor. The SW node can rise very fast as a result of the internal switch turning on.

3.8 Boost Pin (BOOST)

The high side of the floating supply used to turn the integrated N-Channel high-side MOSFET on and off is connected to the boost pin.

3.9 Exposed Thermal Pad Pin (EP)

There is an internal electrical connection between the EP and the P_{GND} and A_{GND} pins.

NOTES:

4.0 DETAILED DESCRIPTION

4.1 Device Overview

The MCP16311/2 is a high-input voltage step-down regulator, capable of supplying 1A typical to a regulated output voltage from 2.0V to 12V. Internally, the trimmed 500 kHz oscillator provides a fixed frequency, while the Peak Current Mode Control architecture varies the duty cycle for output voltage regulation. An internal floating driver is used to turn the high-side integrated N-Channel MOSFET on and off. The power for this driver is derived from an external boost capacitor whose energy is replenished when the low-side N-Channel MOSFET is turned on.

4.1.1 PWM/PFM MODE OPTION

The MCP16311 selects the best operating switching mode (PFM or PWM) for high efficiency across a wide range of load currents. Switching to PFM mode at light-load currents results in a low quiescent current. During the sleep period (between two packets of switching cycles), the MCP16311 draws 44 μA (typical) from the supply line. The switching pulse packets represents a small percentage of the total running cycle, and the overall average current drawn from power line is small.

The disadvantages of PWM/PFM mode are higher output ripple voltage and variable PFM mode frequency. The PFM mode threshold is a function of the input voltage, output voltage and load (see Figure 2-17).

4.1.2 PWM MODE-ONLY OPTION

In the MCP16312 devices, the PFM mode is disabled and the part runs only in PWM over the entire load range. During normal operation, the MCP16312 continues to operate at a constant 500 kHz switching frequency, keeping the output ripple voltage lower than in PFM mode. At lighter loads, the MCP16312 devices begin to skip pulses. Figure 2-18 represents the input voltage versus load current for the pulse skipping threshold in PWM-only mode.

Because the MCP16312 has very low output voltage ripple, it is recommended for noise-sensitive applications.

TABLE 4-1: PART NUMBER SELECTION

Part Number	PWM/PFM	PWM
MCP16311	Х	_
MCP16312	_	X

4.1.3 INTERNAL REFERENCE VOLTAGE (V_{FB})

An integrated precise 0.8V reference combined with an external resistor divider sets the desired converter output voltage. The resistor divider range can vary without affecting the control system gain. High-value resistors consume less current, but are more susceptible to noise. Consult typical applications for the recommended resistors value.

4.1.4 INTERNAL BIAS REGULATOR (V_{CC})

An internal Low Dropout Voltage Regulator (LDO) is used to supply with 5.0V all the internal circuits. The LDO regulates the input voltage (V_{IN}) and can supply enough current (up to 50 mA), to sustain the drivers and internal bias circuitry. The V_{CC} pin must be decoupled to ground with a 1 μF capacitor. In event of a thermal shutdown, the LDO will shut down. There is a short-circuit protection for V_{CC} pin, with a threshold set at 150 mA.

In PFM mode switching, during sleep periods, V_{CC} regulator enters in Low Quiescent Current mode, to avoid unnecessary power dissipation.

Avoid driving any external load using the V_{CC} pin.

4.1.5 INTERNAL COMPENSATION

All control system components necessary for stable operation over the entire device operating range are integrated, including the error amplifier and inductor current slope compensation. To add the proper amount of slope compensation, the inductor value changes along with the output voltage (see Table 5-1).

4.1.6 EXTERNAL COMPONENTS

External components consist of:

- · Input capacitor
- · Output filter (inductor and capacitor)
- · Boost capacitor
- · Resistor divider

The selection of the external inductor, output capacitor and input capacitor is dependent upon the output voltage and the maximum output current.

4.1.7 ENABLE INPUT

The enable input (EN) is used to disable the device. If disabled, the device consumes a minimum current from the input. Once enabled, the internal soft start controls the output voltage rate of rise, preventing high-inrush current and output voltage overshoot.

There is no internally pull-up or down resistor. To enable the converter, the EN pin must be pulled up. To disable the converter, the EN pin must be pulled low.

4.1.8 SOFT START

The internal reference voltage rate of rise is controlled during startup, minimizing the output voltage overshoot and the inrush current.

4.1.9 UNDERVOLTAGE LOCKOUT

An integrated Undervoltage Lockout (UVLO) prevents the converter from starting until the input voltage is high enough for normal operation. The converter will typically start at 4.1V and operate down to 3.6V. Hysteresis is added to prevent starting and stopping during startup, as a result of loading the input voltage source.

4.1.10 OVERTEMPERATURE PROTECTION

Overtemperature protection limits the silicon die temperature to +150°C by turning the converter off. The normal switching resumes at +125°C.

FIGURE 4-1: MCP16311/2 Block Diagram.

4.2 Functional Description

4.2.1 STEP-DOWN OR BUCK CONVERTER

The MCP16311/2 is a synchronous, step-down or buck converter capable of stepping input voltages ranging from 4.4V to 30V down to 2.0V to 24V for $V_{IN} > V_{OUT}$.

The integrated high-side switch is used to chop or modulate the input voltage using a controlled duty cycle. The integrated low-side switch is used to freewheel current when the high-side switch is turned off. High efficiency is achieved by using low-resistance switches and low equivalent series resistance (ESR). inductors and capacitors. When the high-side switch is turned on, a DC voltage is applied to the inductor (V_{IN} -V_{OUT}), resulting in a positive linear ramp of inductor current. When the high-side switch turns off and the low-side switch turns on, the applied inductor voltage is equal to -VOUT, resulting in a negative linear ramp of inductor current. In order to ensure there is no shootthrough current, a dead time where both switches are off is implemented between the high-side switch turning off and the low-side switch turning on, and the low-side switch turning off and the high-side switch turning on.

For steady-state, continuous inductor operation, the positive inductor current ramp must equal the negative current ramp in magnitude. While operating in steady state, the switch duty cycle must be equal to the relationship of V_{OUT}/V_{IN} for constant output voltage regulation, under the condition that the inductor current is continuous, or never reaches zero. For discontinuous inductor current operation, the steady-state duty cycle will be less than V_{OUT}/V_{IN} to maintain voltage regulation. When the inductor current reaches zero, the low-side switch is turned off so that current does not flow in the reverse direction, keeping the efficiency high. The average of the chopped input voltage or SW node voltage is equal to the output voltage, while the average inductor current is equal to the output current.

FIGURE 4-2: Synchronous Step-Down Converter.

4.2.2 PEAK CURRENT MODE CONTROL

The MCP16311/2 integrates a Peak Current Mode Control architecture, resulting in superior AC regulation while minimizing the number of voltage loop compensation components, and their size, for integration. Peak Current Mode Control takes a small portion of the inductor current, replicates it and compares this replicated current sense signal with the output of the integrated error voltage. In practice, the inductor current and the internal switch current are equal during the switch-on time. By adding this peak current sense to the system control, the step-down power train system can be approximated by a 1st order system rather than a 2nd order system. This reduces the system complexity and increases its dynamic performance.

For Pulse-Width Modulation (PWM) duty cycles that exceed 50%, the control system can become bimodal, where a wide pulse followed by a short pulse repeats instead of the desired fixed pulse width. To prevent this mode of operation, an internal compensating ramp is summed into the current sense signal.

4.2.3 PULSE-WIDTH MODULATION

The internal oscillator periodically starts the switching period, which in the MCP16311/2's case occurs every 2 µs or 500 kHz. With the high-side integrated N-Channel MOSFET turned on, the inductor current ramps up until the sum of the current sense and slope compensation ramp exceeds the integrated error amplifier output. Once this occurs, the high-side switch turns off and the low-side switch turns on. The error amplifier output slews up or down to increase or decrease the inductor peak current feeding into the output LC filter. If the regulated output voltage is lower than its target, the inverting error amplifier output rises. This results in an increase in the inductor current to correct for errors in the output voltage. The fixed frequency duty cycle is terminated when the sensed inductor peak current, summed with the internal slope compensation, exceeds the output voltage of the error amplifier. The PWM latch is set by turning off the highside internal switch and preventing it from turning on until the beginning of the next cycle.

The MCP16312 devices will operate in PWM-only mode even during periods of light load operation. By operating in PWM-only mode, the output ripple remains low and the frequency is constant (Figure 2-28). Operating in fixed PWM mode results in lower efficiency during light-load operation (when compared to PFM mode (MCP16311)).

When working close to the boundary conduction threshold, a jitter on the SW node may occur, reflecting in the output voltage. Although the low-frequency output component is very small, it may be desirable to completely eliminate this component. To achieve this, an RC Snubber between the SW node and GND is used.

Typical values for the snubber are: 680 pF and 430Ω . Using such a snubber completely eliminates the jitter on the SW node, but slightly decreases the overall efficiency of the converter.

4.2.4 PFM MODE OPERATION

The MCP16311 devices are capable of automatic operation in normal PWM or PFM mode to maintain high efficiency at all loads. In PFM mode, the output ripple has a variable frequency component that changes with the input voltage and output current. With no load, the quiescent current drawn from the output is very low.

There are two comparators that decide when device starts switching in PFM mode. One of the comparators is monitoring the output voltage and has a reference of 810 mV, with 10 mV hysteresis. If the load current is low, the output rises and triggers the comparator, which will put the logic control of the drivers and other block circuitry (including the internal regulator V_{CC}) in Sleep mode, to minimize the power consumption during the switching cycle's off period. When the output voltage drops below its nominal value, PFM operation pulses one or several times to bring the output back into regulation (Figure 2-26). The second comparator fixes the minimum duty cycle for PFM mode. Minimum duty cycle in PFM mode depends on the sensed peak current and input voltage. As a result, the PFM-to-PWM mode threshold depends on load current and value of the input voltage (Figure 2-17). If the output load current rises above the upper threshold, the MCP16311 transitions smoothly into PWM mode.

4.2.5 HIGH-SIDE DRIVE

The MCP16311/2 features an integrated high-side N-Channel MOSFET for high efficiency step-down power conversion. An N-Channel MOSFET is used for its low resistance and size (instead of a P-Channel MOSFET). The N-Channel MOSFET gate must be driven above its source to fully turn on the device, resulting in a gate-drive voltage above the input to turn on the high side N-Channel. The high-side N-channel source is connected to the inductor and boost cap or switch node. When the high-side switch is off and the low-side is on, the inductor current flows through the low-side switch, providing a path to recharge the boost cap from the boost voltage source. The voltage for the boost cap is supplied from the internal regulator (VCC). An internal boost blocking diode is used to prevent current flow from the boost cap back into the regulator during the internal switch on time. If the boost voltage decreases significantly, the low side will be forced low for 90 ns in order to charge the boost capacitor.

NOTES:

5.0 APPLICATION INFORMATION

5.1 Typical Applications

The MCP16311/2 synchronous step-down converter operates over a wide input range, up to 30V maximum. Typical applications include generating a bias or V_{DD} voltage for PIC[®] microcontrollers, digital control system bias supply for AC-DC converters and 12V industrial input and similar applications.

5.2 Adjustable Output Voltage Calculations

To calculate the resistor divider values for the MCP16311/2 adjustable version, use Equation 5-1. R_{TOP} is connected to V_{OUT} , R_{BOT} is connected to A_{GND} , and both are connected to the V_{FB} input pin.

EQUATION 5-1: RESISTOR DIVIDER CALCULATION

$$R_{TOP} = R_{BOT} \times \left(\frac{V_{OUT}}{V_{FB}} - I \right)$$

EXAMPLE 5-1: 3.3V RESISTOR DIVIDER

 $V_{OUT} = 3.3V$

 $V_{FB} = 0.8V$

 $R_{BOT} = 10 k\Omega$

 $R_{TOP} = 31.25 \text{ k}\Omega \text{ (standard value = } 31.2 \text{ k}\Omega)$

V_{OUT} = 3.296V (using standard value)

EXAMPLE 5-2: 5.0V RESISTOR DIVIDER

 $V_{OUT} = 5.0V$

 $V_{FR} = 0.8V$

 $R_{BOT} = 10 k\Omega$

 $R_{TOP} = 52.5 \text{ k}\Omega \text{ (standard value = 52.3 k}\Omega)$

V_{OLIT} = 4.984V (using standard values)

EXAMPLE 5-3: 12.0V RESISTOR DIVIDER

 $V_{OUT} = 12.0V$

 $V_{ER} = 0.8V$

 $R_{BOT} = 10 \text{ k}\Omega$

 $R_{TOP} = 140 \text{ k}\Omega \text{ (standard value = 140 k}\Omega)$

The error amplifier is internally compensated to ensure loop stability. External resistor dividers, inductance and output capacitance, all have an impact on the control system and should be selected carefully and evaluated for stability. A 10 k Ω bottom resistor is recommended as a good trade-off for quiescent current and noise immunity.

5.3 General Design Equations

The step down converter duty cycle can be estimated using Equation 5-2 while operating in Continuous Inductor Current mode. This equation accounts for the forward drop of the two internal N-Channel MOSFETS. As load current increases, the voltage drop in both internal switches will increase, requiring a larger PWM duty cycle to maintain the output voltage regulation. Switch voltage drop is estimated by multiplying the switch current times the switch resistance or R_{DSON}.

EQUATION 5-2: CONTINUOUS INDUCTOR CURRENT DUTY CYCLE

$$D = \frac{V_{OUT} + (I_{LSW} \times R_{DSONL})}{V_{IN} - (I_{HSW} \times R_{DSONH})}$$

The MCP16311/2 device features an integrated slope compensation to prevent the bimodal operation of the PWM duty cycle. Internally, half of the inductor current down slope is summed with the internal current sense signal. For the proper amount of slope compensation, it is recommended to keep the inductor down-slope current constant by varying the inductance with V_{OUT} , where K = 0.22 V/ μ H.

EQUATION 5-3:

$$K = V_{OUT}/L$$

For example, for V_{OUT} = 3.3V, an inductance of 15 μH is recommended.

TABLE 5-1: RECOMMENDED INDUCTOR VALUES

V _{OUT}	K	L _{STANDARD}
2.0V	0.20	10 μH
3.3V	0.22	15 µH
5.0V	0.23	22 µH
12V	0.21	56 µH
15V	0.22	68 µH

5.4 Input Capacitor Selection

The step-down converter input capacitor must filter the high-input ripple current, that results from pulsing or chopping the input voltage. The MCP16311/2 input voltage pin is used to supply voltage for the power train and as a source for internal bias. A low equivalent series resistance (ESR), preferably a ceramic capacitor, is recommended. The necessary capacitance is dependent upon the maximum load current and source impedance. Three capacitor parameters to keep in mind are the voltage rating, equivalent series resistance and the temperature rating. For wide temperature range applications, a multi-layer X7R dielectric is recommended, while for applications with limited temperature range, a multi-layer X5R dielectric is acceptable. Typically, input capacitance between 10 µF and 20 µF is sufficient for most applications. For applications with 100 mA to 200 mA load, a 4.7 μF to 2.2 μF X7R capacitor can be used, depending on the input source and its impedance. In case of an application with high variations of the input voltage, a higher capacitor value is recommended. The input capacitor voltage rating must be V_{IN} plus margin.

Table 5-2 contains the recommended range for the input capacitor value.

5.5 Output Capacitor Selection

The output capacitor provides a stable output voltage during sudden load transients, and reduces the output voltage ripple. As with the input capacitor, X5R and X7R ceramic capacitors are well suited for this application. For typical applications, the output capacitance can be as low as 10 μF ceramic and as high as 100 μF electrolytic. In a typical application, a 20 μF output capacitance usage will result in a 10 mV output ripple.

The amount and type of output capacitance and equivalent series resistance will have a significant effect on the output ripple voltage and system stability. The range of the output capacitance is limited due to the integrated compensation of the MCP16311/2. See Table 5-2 for the recommended output capacitor range.

The output voltage capacitor rating should be a minimum of $\ensuremath{\mathrm{V}_{\mathrm{OUT}}}$ plus margin.

TABLE 5-2: CAPACITOR VALUE RANGE

Parameter	Min.	Max.
C _{IN}	2.2 µF	None
C _{OUT}	20 μF	None

5.6 Inductor Selection

The MCP16311/2 is designed to be used with small surface-mount inductors. Several specifications should be considered prior to selecting an inductor. To optimize system performance, low DCR inductors should be used.

To optimize system performance, the inductance value is determined by the output voltage (Table 5-1) so the inductor ripple current is somewhat constant over the output voltage range.

EQUATION 5-4: INDUCTOR RIPPLE CURRENT

$$\varDelta_{I_L} = \frac{V_{IN} - V_{OUT}}{L} \times t_{ON}$$

EXAMPLE 5-4:

 $V_{IN} = 12V$ $V_{OUT} = 3.3V$ $I_{OUT} = 800 \text{ mA}$

EQUATION 5-5: INDUCTOR PEAK CURRENT

$$I_{LPK} = \frac{\Delta I_L}{2} + I_{OUT}$$

Where:

Inductor ripple current = 319 mA Inductor peak current = 960 mA

For this example, an inductor with a current saturation rating of minimum 960 mA is recommended. Low DCR inductors result in higher system efficiency. A trade-off between size, cost and efficiency is made to achieve the desired results.

TABLE 5-3: MCP16311/2 RECOMMENDED 3.3V V_{OUT} INDUCTORS

Part Number	Value (µH)	DCR (೧)	I _{SAT} (A)	Size WxLxH (mm)

5.7 Boost Capacitor

The boost capacitor is used to supply current for the internal high-side drive circuitry that is above the input voltage. The boost capacitor must store enough energy to completely drive the high-side switch on and off. A 100 nF X5R or X7R capacitor is recommended for all applications. The boost capacitor maximum voltage is 5V.

5.8 V_{cc} Capacitor

The V_{CC} internal bias regulates at 5V. The V_{CC} pin is current limited to 50 mA and protected to a short-circuit condition at 150 mA load. The V_{CC} regulator must sustain all load and line transients because it supplies the internal drivers for power switches. For stability reasons, the V_{CC} capacitor must be at least 1 μF X7R ceramic for extended temperature range, or X5R for limited temperature range.

5.9 MCP16312 – LED Constant Current Driver

MCP16312 can be used to drive an LED or a string of LEDs. The process of transforming the MCP16312 from a constant voltage source into a constant current source is simple. It implies that the sensing/feedback for the current is on the low-side, by adding a resistor in series with the string of LEDs.

When using the MCP16312 as an LED driver, care must be taken when selecting the sense resistor. Due to the high feedback voltage of 0.8V, there will be significant losses on the sense resistor, so a larger package with better power dissipation must be selected.

Another important aspect when creating such an application is the value of the inductor. The value of the inductor needs to follow Equation 5-3 or, as a guideline, Table 5-1, where the output voltage is approximated as the sum of the forward voltages of the LEDs and a 0.8V headroom for the sense resistor. A typical application is shown in Figure 5-3.

The following equations are used to determine the value and the losses for the sense resistor:

EQUATION 5-6:

$$R_B = \frac{V_{FB}}{I_{LED}}$$

$$P_{LOSSES} = V_{FB} \times I_{LED}$$
 Where:
$$V_{\text{FB}} = \text{Feedback Voltage}$$

EXAMPLE 5-5:

 $I_{LED} = 400 \text{ mA}$ $V_{FB} = 0.8 \text{V}$

 $V_F = 1 \times 3.2V$ (one white LED is used)

 $R_B = 2\Omega$

 $P_{LOSSES} = 0.32 \text{ W (sense resistor losses)}$

 $L = 22 \mu H$

5.10 Thermal Calculations

The MCP16311/2 is available in MSOP-8 and DFN-8 packages. By calculating the power dissipation and applying the package thermal resistance (θ_{JA}), the junction temperature is estimated. The maximum continuous junction temperature rating for the MCP16311/2 is +125°C.

To quickly estimate the internal power dissipation for the switching step-down regulator, an empirical calculation using measured efficiency can be used. Given the measured efficiency, the internal power dissipation is estimated in Equation 5-7. This power dissipation includes all internal and external component losses. For a quick internal estimate, subtract the estimated inductor DCR loss from the P_{DIS} calculation in Equation 5-7.

EQUATION 5-7: TOTAL POWER DISSIPATION ESTIMATE

$$P_{DIS} = \frac{V_{OUT} \times I_{OUT}}{Efficiency} - (V_{OUT} \times I_{OUT})$$

The difference between the first term, input power, and the second term, power delivered, is the total system power dissipation. The inductor losses are estimated by $P_L = I_{OUT}^2 \, x \, L_{DCR}$.

EXAMPLE 5-6: POWER DISSIPATION – MCP16311/2 MSOP PACKAGE

 $V_{IN} = 12V$

 $V_{OUT} = 5.0V$

 $I_{OUT} = 0.8A$

Efficiency = 92.5%

Total System Dissipation = 324 mW

 $L_{DCR} = 0.15 \Omega$

 $P_L = 96 \text{ mW}$

MCP16311/2 internal power dissipation estimate:

 $P_{DIS} - P_{L} = 228 \text{ mW}$

 $\theta_{JA} = 211^{\circ}C/W$

Estimated Junction = +48.1°C

Temperature Rise

EXAMPLE 5-7: POWER DISSIPATION – MCP16311/2 DFN PACKAGE

 $V_{IN} = 12V$

 $V_{OUT} = 3.3V$

 $I_{OUT} = 0.8A$

Efficiency = 90%

Total System Dissipation = 293 mW

 $L_{DCR} = 0.15 \Omega$

 $P_L = 96 \text{ mW}$

MCP16311 internal power dissipation estimate:

 $P_{DIS} - P_{L} = 197 \text{ mW}$

 $\theta_{JA} = 68^{\circ}C/W$

Estimated Junction = +13.4°C

Temperature Rise

5.11 Printed Circuit Board (PCB) Layout Information

Good PCB layout techniques are important to any switching circuitry, and switching power supplies are no different. When wiring the switching high-current paths, short and wide traces should be used. Therefore, it is important that the input and output capacitors be placed as close as possible to the MCP16311/2, to minimize the loop area.

The feedback resistors and feedback signal should be routed away from the switching node and the switching current loop. When possible, ground planes and traces should be used to help shield the feedback signal and minimize noise and magnetic interference.

A good MCP16311/2 layout starts with the placement of the input capacitor, which supplies current to the input of the circuit when the switch is turned on. In addition to supplying high-frequency switch current, the input capacitor also provides a stable voltage source for the internal MCP16311/2 circuitry. Unstable PWM operation can result if there are excessive transients or ringing on the $V_{\mbox{\scriptsize IN}}$ pin of the MCP16311/2 device. In Figure 5-1, the input capacitors are placed close to the V_{IN} pins. A ground plane on the bottom of the board provides a low-resistive and low-inductive path for the return current. The next priority in placement is the freewheeling current loop formed by output capacitors and inductance (L1), while strategically placing the output capacitor ground return close to the input capacitor ground return. Then, CBOOST should be placed between the boost pin and the switch node pin. This leaves space close to the MCP16311/2 V_{FB} pin to place R_{TOP} and R_{BOT}. The feedback loop must be routed away from the switch node, so noise is not coupled into the high-impedance V_{FB} input.

Component	Value
C _{IN}	2 x 10 μF
C _{OUT}	2 x 10 μF
L1	22 µH
R _T	52.3 kΩ
R_B	10 kΩ
R _{EN}	1 ΜΩ
C _{VCC}	1 μF
C _{BOOST}	0.1 µF

NOTES:

Note the following details of the code protection feature on Microchip devices:

- · Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the
 intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our
 knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data
 Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. ПОСТАВКА ЭЛЕКТРОННЫХ КОМПОНЕНТОВ

многоканальный

Общество с ограниченной ответственностью «МосЧип» ИНН 7719860671 / КПП 771901001 Адрес: 105318, г.Москва, ул.Щербаковская д.3, офис 1107

Данный компонент на территории Российской Федерации Вы можете приобрести в компании MosChip.

Для оперативного оформления запроса Вам необходимо перейти по данной ссылке:

http://moschip.ru/get-element

Вы можете разместить у нас заказ для любого Вашего проекта, будь то серийное производство или разработка единичного прибора.

В нашем ассортименте представлены ведущие мировые производители активных и пассивных электронных компонентов.

Нашей специализацией является поставка электронной компонентной базы двойного назначения, продукции таких производителей как XILINX, Intel (ex.ALTERA), Vicor, Microchip, Texas Instruments, Analog Devices, Mini-Circuits, Amphenol, Glenair.

Сотрудничество с глобальными дистрибьюторами электронных компонентов, предоставляет возможность заказывать и получать с международных складов практически любой перечень компонентов в оптимальные для Вас сроки.

На всех этапах разработки и производства наши партнеры могут получить квалифицированную поддержку опытных инженеров.

Система менеджмента качества компании отвечает требованиям в соответствии с ГОСТ Р ИСО 9001, ГОСТ РВ 0015-002 и ЭС РД 009
