

### FEATURES

- Precision 2.5 V to 5 V power supply monitor
- 7 reset threshold options: 2.19 V to 4.63 V
- 140 ms (minimum) reset timeout
- Watchdog timer with 1.6 sec timeout (ADM823, ADM824)
- Manual reset input (ADM823, ADM825)
- Push-pull output stages
  - $\overline{\text{RESET}}$  (ADM823)
  - $\overline{\text{RESET}}$ , RESET (ADM824/ADM825)
- Low power consumption: 5  $\mu\text{A}$
- Guaranteed reset output valid to  $V_{\text{CC}} = 1\text{ V}$
- Power supply glitch immunity
- Specified over automotive temperature range
- 5-lead SC70 and SOT-23 packages

### APPLICATIONS

- Microprocessor systems
- Computers
- Controllers
- Intelligent instruments
- Portable equipment

### GENERAL DESCRIPTION

The ADM823/ADM824/ADM825 are supervisory circuits that monitor power supply voltage levels and code execution integrity in microprocessor-based systems. In addition to providing power-on reset signals, an on-chip watchdog timer can reset the microprocessor if it fails to strobe within a preset timeout period. A reset signal can also be asserted by an external push-button, through a manual reset input. The three parts feature different combinations of watchdog input, manual reset input, and output stage configuration, as shown in Table 1.

Figure 1.

These parts are available in a choice of seven reset threshold options ranging from 2.19 V to 4.63 V. The reset and watchdog timeout periods are fixed at 140 ms (minimum) and 1.6 sec (typical), respectively.

The ADM823/ADM824/ADM825 are available in 5-lead SC70 and SOT-23 packages and typically consume only 5  $\mu\text{A}$ , making them suitable for use in low power, portable applications.

## ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$ , unless otherwise noted.

**Table 3.**

Parameter	Rating
$V_{CC}$	-0.3 V to +6 V
Output Current (RESET, $\overline{\text{RESET}}$ )	20 mA
All Other Pins	-0.3 V to ( $V_{CC} + 0.3$ V)
Operating Temperature Range	-40°C to +125°C
Storage Temperature Range	-65°C to +150°C
$\theta_{JA}$ Thermal Impedance	
SC70	146°C/W
SOT-23	270°C/W
Lead Temperature	
Soldering (10 sec)	300°C
Vapor Phase (60 sec)	215°C
Infrared (15 sec)	220°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### ESD CAUTION

#### **ESD (electrostatic discharge) sensitive device.**

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

Figure 2. ADM823 Pin Configuration

Figure 3. ADM824 Pin Configuration

Figure 4. ADM825 Pin Configuration

Table 4. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	$\overline{\text{RESET}}$	Active Low, Push-Pull Reset Output. Asserted whenever $V_{CC}$ is below the reset threshold, $V_{TH}$ .
2	GND	Ground.
3	$\overline{\text{MR}}$ (ADM823)	Manual Reset Input. This is an active low input which, when forced low for at least 1 $\mu\text{s}$ , generates a reset. It features a 52 k $\Omega$ internal pull-up.
4	RESET (ADM824/ADM825)	Active High, Push-Pull Reset Output.
	WDI (ADM823/ADM824)	Watchdog Input. Generates a reset if the voltage on the pin remains low or high for the duration of the watchdog timeout. The timer is cleared if a logic transition occurs on this pin or if a reset is generated.
5	$\overline{\text{MR}}$ (ADM825)	Manual Reset Input. This is an active low input which, when forced low for at least 1 $\mu\text{s}$ , generates a reset. It features a 52 k $\Omega$ internal pull-up.
	$V_{CC}$	Power Supply Voltage Being Monitored.

## CIRCUIT DESCRIPTION

The ADM823/ADM824/ADM825 provide microprocessor supply voltage supervision by controlling the reset input of the microprocessor. Code execution errors are avoided during power-up, power-down, and brownout conditions by asserting a reset signal when the supply voltage is below a preset threshold. Errors are also avoided by allowing supply voltage stabilization with a fixed timeout reset pulse after the supply voltage rises above the threshold. In addition, problems with microprocessor code execution can be monitored and corrected with a watchdog timer (ADM823/ADM824). By including watchdog strobe instructions in microprocessor code, a watchdog timer can detect whether the microprocessor code breaks down or becomes stuck in an infinite loop. If this happens, the watchdog timer asserts a reset pulse that restarts the microprocessor in a known state. If the user detects a problem with the system's operation, a manual reset input is available (ADM823/ADM825) to reset the microprocessor with an external push-button, for example.

### RESET OUTPUT

The ADM823 features an active low, push-pull reset output, and the ADM824/ADM825 feature dual active low and active high push-pull reset outputs. For active low and active high outputs, the reset signal is guaranteed to be logic low and logic high, respectively, for  $V_{CC} \geq 1\text{ V}$ .

The reset output is asserted when  $V_{CC}$  is below the reset threshold ( $V_{TH}$ ), when  $\overline{MR}$  is driven low, or when WDI is not serviced within the watchdog timeout period ( $t_{WD}$ ). Reset remains asserted for the duration of the reset active timeout period ( $t_{RP}$ ) after  $V_{CC}$  rises above the reset threshold, after  $\overline{MR}$  transitions from low to high, or after the watchdog timer times out. Figure 15 illustrates the behavior of the reset outputs.

Figure 15. Reset Timing Diagram

### MANUAL RESET INPUT

The ADM823/ADM825 feature a manual reset input ( $\overline{MR}$ ) which, when driven low, asserts the reset output. When  $\overline{MR}$  transitions from low to high, reset remains asserted for the duration of the reset active timeout period before deasserting. The  $\overline{MR}$  input has a 52 k $\Omega$  internal pull-up so that the input is always high when unconnected. An external push-button switch can be connected between  $\overline{MR}$  and ground so that the user can generate a reset. Debounce circuitry for this purpose is integrated on chip. Noise immunity is provided on the  $\overline{MR}$  input and fast, negative-going transients of up to 100 ns (typical) are ignored. A 0.1  $\mu\text{F}$  capacitor between  $\overline{MR}$  and ground provides additional noise immunity.

### WATCHDOG INPUT

The ADM823/ADM824 feature a watchdog timer that monitors microprocessor activity. A timer circuit is cleared with every low-to-high or high-to-low logic transition on the watchdog input pin (WDI), which detects pulses as short as 50 ns. If the timer counts through the preset watchdog timeout period ( $t_{WD}$ ), reset is asserted. The microprocessor is required to toggle the WDI pin to avoid being reset. Failure of the microprocessor to toggle WDI within the timeout period, therefore, indicates a code execution error, and the reset pulse generated restarts the microprocessor in a known state.

In addition to logic transitions on WDI, the watchdog timer is also cleared by a reset assertion due to an undervoltage condition on  $V_{CC}$  or by  $\overline{MR}$  being pulled low. When reset is asserted, the watchdog timer is cleared and does not begin counting again until reset is deasserted. The watchdog timer can be disabled by leaving WDI floating or by three-stating the WDI driver.

Figure 16. Watchdog Timing Diagram

## APPLICATIONS INFORMATION

### WATCHDOG INPUT CURRENT

To minimize the watchdog input current (and minimize overall power consumption), leave WDI low for the majority of the watchdog timeout period. When driven high, WDI can draw as much as 160  $\mu$ A. Pulsing WDI low-high-low at a low duty cycle reduces the effect of the large input current. When WDI is unconnected, a window comparator disconnects the watchdog timer from the reset output circuitry so that reset is not asserted when the watchdog timer times out.

### NEGATIVE-GOING $V_{CC}$ TRANSIENTS

To avoid unnecessary resets caused by fast power supply transients, the ADM823/ADM824/ADM825 are equipped with glitch rejection circuitry. The typical performance characteristic in Figure 12 plots  $V_{CC}$  transient duration vs. the transient magnitude. The curves show combinations of transient magnitude and duration for which a reset is not generated for 4.63 V and 2.93 V reset threshold parts. For example, with the 2.93 V threshold, a transient that goes 100 mV below the threshold and lasts 8  $\mu$ s typically does not cause a reset, but if the transient is any larger in magnitude or duration, a reset is generated. An optional 0.1  $\mu$ F bypass capacitor mounted close to  $V_{CC}$  provides additional glitch rejection.

### ENSURING RESET VALID TO $V_{CC} = 0$ V

Both active low and active high reset outputs are guaranteed to be valid for  $V_{CC}$  as low as 1 V. However, by using an external resistor with push-pull configured reset outputs, valid outputs for  $V_{CC}$  as low as 0 V are possible. For an active low reset output, a resistor connected between RESET and ground pulls the output low when it is unable to sink current. For an active high reset output, a resistor connected between RESET and  $V_{CC}$  pulls the output high when it is unable to source current. A large resistance such as 100 k $\Omega$  should be used so that the reset output is not overloaded when  $V_{CC}$  is above 1 V.

Figure 17. Ensuring Reset Valid to  $V_{CC} = 0$  V

04634-017

### WATCHDOG SOFTWARE CONSIDERATIONS

In implementing the microprocessor watchdog strobe code, quickly switching WDI low-to-high and then high-to-low (minimizing WDI high time) is desirable for current consumption reasons. However, a more effective way of using the watchdog function can be considered.

A low-high-low WDI pulse within a given subroutine prevents the watchdog timing out. However, if the subroutine becomes stuck in an infinite loop, the watchdog cannot detect this condition because the subroutine continues to toggle WDI. A more effective coding scheme for detecting this error involves using a slightly longer watchdog timeout. In the program that calls the subroutine, WDI is set high (see Figure 18). The subroutine sets WDI low when it is called. If the program executes without error, WDI is toggled high and low with every loop of the program. If the subroutine enters an infinite loop, WDI is kept low, the watchdog times out, and the microprocessor is reset.

### Вы можете приобрести в компании MosChip.

Для оперативного оформления запроса Вам необходимо перейти по данной ссылке:

<http://moschip.ru/get-element>

Вы можете разместить у нас заказ для любого Вашего проекта, будь то серийное производство или разработка единичного прибора.

В нашем ассортименте представлены ведущие мировые производители активных и пассивных электронных компонентов.

Нашей специализацией является поставка электронной компонентной базы двойного назначения, продукции таких производителей как XILINX, Intel (ex.ALTERA), Vicor, Microchip, Texas Instruments, Analog Devices, Mini-Circuits, Amphenol, Glenair.

Сотрудничество с глобальными дистрибьюторами электронных компонентов, предоставляет возможность заказывать и получать с международных складов практически любой перечень компонентов в оптимальные для Вас сроки.

На всех этапах разработки и производства наши партнеры могут получить квалифицированную поддержку опытных инженеров.

Система менеджмента качества компании отвечает требованиям в соответствии с ГОСТ Р ИСО 9001, ГОСТ РВ 0015-002 и ЭС РД 009
