

General Description

DA7217 is a high-performance, low-power audio codec optimized for use in headsets or wearable devices. It has differential headphone outputs for use inside headset devices, offering excellent left to right channel separation and common mode noise rejection. DA7217 also has a stereo DAC to headphone output path and ultra-low power operating modes to support always-on audio detect applications.

DA7217 contains two analog microphone input paths, or up to four digital microphone input paths, or a combination of both. The other chip in this family, the DA7218, has single-ended headphone outputs, and has been designed with headphone detect for use in accessories.

Key Features

- High performance stereo DAC to headphone
 playback path with 110 dB dynamic range
- 4 mW stereo playback power consumption
- DAC digital filters with audio and voice mode options, five-band equalizer and five programmable biguad stages
- Dedicated low-latency digital sideband filter with three programmable biquad stages
- High performance microphone to ADC record path with 105 dB dynamic range
- 2.5 mW stereo record power consumption
- ADC digital filters with audio and voice mode options
- 500 µW always-on record mode with automatic level detection
- Hybrid analog / digital automatic level control to dynamically control the record level
- Shutdown mode offering current consumption during standby of 2.5 µA
- Two low-noise microphone bias regulators with programmable output voltage and ultralow power mode
- A high efficiency two-level, true-ground charge pump for generating class-G headphone supplies
- Voice mode filtering up to 32 kHz

Flexible digital mixing from all seven inputs to all six outputs with independent gain on each mixer path

- Ability to run the ADCs at a different sample rate to the DACs on a single I²S interface
- Digital tone generator with built-in support for DTMF
- System controller for simplified, pop-free startup and shutdown
- Phase-locked loop with sample rate tracking supporting MCLK frequencies from 2 MHz to 54 MHz
- Automatic tuning of on-chip reference oscillator for clock-free operation in low-power modes
- 4-wire digital audio interface with support for I²S, four-channel I²S, TDM and other audio formats
- 2-wire I²C compatible control interface with support for High Speed mode up to 3.4 MHz
- 24-bit data at up to 96 kHz sample rate
- The headphone amplifier can be run directly from the supply, thus eliminating the need for charge pump capacitors

Applications

- Hearables
- Wireless and wired headphones
- Wireless and wired headsets

2 Terminology

- [1] Crosstalk (dB) is the level difference between the active path output and the idle path measured signal level, at the test signal frequency. The active path is configured and supplied with an input signal capable of driving a full scale output, with the signal measured at the output of the specified idle path.
- [2] Mute Attenuation is the difference in level between the full scale output signal and the output with mute applied.
- [3] Channel Separation (dB) [left-to-right and right-to-left] is the difference in level between the active channel (driven to maximum full scale output) and the signal level measured in the idle channel at the test signal frequency. The active channel is configured and supplied with an input signal capable of driving a full scale output, with the signal measured at the output of the associated idle channel.
- [4] PSRR is the ratio of a given power supply change relative to the output signal that results from it. PSRR is measured under quiescent signal path conditions.
- [5] SNR is the difference in level between the maximum full scale output signal and the output with no input signal applied.
- [6] THD+N is the level of the rms value of the sum of harmonic distortion products plus noise in the specified bandwidth relative to the amplitude of the measured output signal.

All performance measurements carried out with 20 kHz low pass filter, and where noted an Aweighted filter. Failure to use such a filter will result in higher THD and lower SNR readings than are found in the Electrical Characteristics. The low-pass filter removes out of band noise; although it is not audible it may affect dynamic specification values.

4.1 Input Pins

4.1.1 MIC1_P (DMIC1CLK)

MIC1_P is the positive differential input for the first analog microphone channel. It can be used as a single-ended input (see Figure 8).

Alternatively for digital microphones, MIC1_P is used to provide a clock output.

4.1.2 MIC1_N (DMIC1IN)

MIC1_N is the negative differential input for the first analog microphone channel. It can be used as a single-ended input.

Alternatively for digital microphones and active noise cancelling (ANC) applications, MIC1_N is used as a pulse density modulated (PDM) data input.

4.1.3 MIC2_P (DMIC2CLK)

MIC2_P is the positive differential input for the second analog microphone channel. It can be used as a single-ended input.

Alternatively for digital microphones, MIC2_P is used to provide a clock output.

4.1.4 MIC2_N (DMIC2IN)

MIC2_N is the negative differential input for the second analog microphone channel. It can be used as a single-ended input.

Alternatively for digital microphones and ANC applications, MIC2_N is used as a PDM data input.

4.1.5 MCLK

MCLK is the master clock input pin. It is used as the main system clock either directly or via the PLL.

4.1.6 SCL

SCL is the control interface (I²C) clock input and is used in conjunction with SDA to control the device.

| Datasheet | Revision 3.3 | 01-Feb-2019 |
|-----------|--------------|-------------|
| Datasneet | Revision 3.3 | 01-Feb-2019 |

4.1.7 AD

AD is used to select between one of two possible I^2C slave addresses by connecting the pin to GND or VDD_IO. (High = 1B, Low = 1A).

4.1.8 **DATIN**

DATIN is the data input pin which forms part of the digital audio interface (DAI). It is used to present audio playback data to the device.

4.2 Output Pins

4.2.1 nIRQ

nIRQ is the open drain active-low interrupt output to alert the host to either an accessory or a leveldetect event.

4.2.2 **DATOUT**

DATOUT is the data output pin, which forms part of the DAI.

4.3 **Bi-Directional Pins**

4.3.1 SDA

SDA is the control interface (I²C) data input/output and is used in conjunction with SCL to control the device.

4.3.2 BCLK

BCLK is the bit clock input/output pin which forms part of the DAI. It is used to clock audio data bits into or out from the device or both.

4.3.3 WCLK

WCLK is the word clock input/output pin that forms part of the DAI.

4.4 Differential Headphone Pins

4.4.1 HPL_P

HPL_P is the positive left-channel headphone output for a headphone speaker connected between HPL_P and HPL_N.

4.4.2 HPL_N

HPL_N is the negative left-channel headphone output for a headphone speaker connected between HPL_P and HPL_N.

4.4.3 HPR_P

HPR_P is the positive right-channel headphone output for a headphone speaker connected between HPR_P and HPR_N.

4.4.4 HPR_N

HPR_N is the negative right-channel headphone output for a headphone speaker connected between HPR_P and HPR_N.

|--------|----|---|----|
| ат | 26 | n | ١. |
| αι | as | | |

01-Feb-2019

4.5 Charge Pump Pins

4.5.1 HPCSP

HPCSP is the positive output from the headphone charge pump. This pin should be connected to ground via a reservoir capacitor.

4.5.2 HPCSN

HPCSN is the negative output from the headphone charge pump. If using the charge pump, this pin must be connected to ground via a reservoir capacitor. If the charge pump is not being used, then this pin should be tied directly to ground.

4.5.3 HPCFP

HPCFP is one of the flying capacitor connections required by the headphone charge pump. If the charge pump is in use it must be connected to HPCFN via a capacitor. If the charge pump is not being used, then this pin can be left floating.

4.5.4 HPCFN

HPCFP is one of the flying capacitor connections required by the headphone charge pump. If the charge pump is in use it must be connected to HPCFP via a capacitor. If the charge pump is not being used, then this pin can be left floating.

4.6 References

4.6.1 VMID

VMID is mid-rail reference decoupling capacitor connection.

4.6.2 DACREF

DACREF is the DAC reference decoupling capacitor connection.

4.6.3 VREF

VREF is the bandgap reference decoupling capacitor connection.

4.6.4 MICBIAS1

MICBIAS1 is the first of two MICBIAS outputs. This must be decoupled with a 1 µF capacitor

4.6.5 MICBIAS2

MICBIAS2 is the second of two MICBIAS outputs. This must be decoupled with a 1 µF capacitor.

4.6.6 VDDDIG

VDDDIG is the internal digital supply rail decoupling pin and is used to monitor the LDO output. This must be decoupled with a 1 μ F capacitor.

4.7 Supply Pins

4.7.1 VDD

VDD is main analog supply pin. It supplies all the analog circuits except the MICBIAS outputs and the HPAMP outputs.

| Datasheet | Revision 3.3 | | 01-Feb-2019 |
|-----------|---------------------|--|-------------|
|-----------|---------------------|--|-------------|

DA7217

Ultra-Low Power Stereo Codec

4.7.2 VDD_IO

VDD_IO is the supply pin for the digital input/output signals.

4.7.3 VDD_MIC

VDD_MIC is the supply pin for the MICBIAS outputs.

4.8 Ground Pins

4.8.1 GND

GND is one of the two ground reference pins (the other is GND_CP) on the device. Connect this pin to a ground plane as close as possible to the device.

4.8.2 **GND_CP**

GND_CP is one of the two ground reference pins (the other is GND) on the device. Connect this pin to a ground plane as close as possible to the device.

Datasheet

5 Absolute Maximum Ratings

Table 3: Absolute Maximum Ratings (Note 1)

| Parameter | Description | Conditions | Min | Max | Unit |
|--------------------|--------------------------------|---|------|-----------------------------|------|
| | Storage temperature | | -65 | +165 | °C |
| Ta | Operating temperature | | -40 | +85 | °C |
| V _{DD} | Main supply voltage | | -0.3 | +2.75 | V |
| V _{DD_IO} | Digital IO supply voltage | | -0.3 | +5.5 | V |
| VDD_MIC | Microphone bias supply voltage | | -0.3 | +5.5 | V |
| Vddio | Digital IO pins | SDA, SCL, AD, BCLK, WCLK, DATIN, DATOUT, MCLK, nIRQ | -0.3 | V _{DD_IO} + 0.3 | V |
| | Digital microphone IO pins | DMIC1CLK, DMIC1IN | -0.3 | VMICBIAS1 + 0.3 | V |
| | Digital microphone IO pins | DMIC2CLK, DMIC2IN | -0.3 | V _{MICBIAS2} + 0.3 | V |
| | Analog input pins | MIC1_P, MIC1_N, MIC2_P, MIC2_N | -0.3 | V _{DD} + 0.3 | V |
| | Package thermal resistance | | 60 | | °CW |
| Vesd_hbm | ESD susceptibility | Human body model (HBM) | | 2 | kV |

Note 1 Stresses beyond those listed under 'Absolute maximum ratings' may cause permanent damage to the device. These are stress ratings only, so functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specification are not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

6 Recommended Operating Conditions

Table 4: Recommended Operating Conditions

| Parameter | Description | Conditions | Min | Тур | Max | Unit |
|--------------------|--------------------------------|------------|------|-----|-------|------|
| Ta | Operating temperature | | -25 | | +85 | °C |
| V _{DD} | Main supply voltage | | +1.7 | | +2.65 | V |
| V _{DD_IO} | Digital IO supply voltage | | +1.5 | | +3.6 | V |
| VDD_MIC | Microphone bias supply voltage | | +1.8 | | +3.6 | V |

7 Electrical Characteristics

Unless otherwise stated, test conditions are as follows: $V_{DD} = V_{DD_{-}IO} = 1.8 \text{ V}, V_{DD_{-}MIC} = 3.3 \text{ V}, V_{DDDIG} = 1.05 \text{ V}, T_a = 25 \text{ °C}, \text{MCLK} = 12.288 \text{ MHz}, \text{SR} = 48 \text{ kHz}, \text{PLL} = \text{Bypass mode}, \text{Slave mode}.$

Table 5: Power Consumption

| Description | Conditions (Note 1) | Min | Тур | Max | Unit |
|---|---|-----|-----|-----|------|
| Powerdown mode | | | 2.5 | 7 | μA |
| Digital playback to headphone, no load | DACL/R to HP_L/R, quiescent | | 4 | | mW |
| Digital playback to headphone, with load | DACL/R to HP_L/R, 32 Ω load, 0.1 mW at 0 dBFS | | 7.7 | | mW |
| Microphone stereo record | MICL/R to ADCL/R | | 2.5 | | mW |
| Microphone stereo record and digital playback to Headphone, no load | MICL/R to ADCL/R and DACL/R to HP_L/R, quiescent | | 5.5 | | mW |
| Microphone stereo record and digital playback to headphone, with load | MICL/R to ADCL/R and DACL/R to HP_L/R, 32 Ω load, 0.1 mW at 0 dBFS | | 8.8 | | mW |

Note 1 $V_{DD} = V_{DD_IO} = V_{DD_MIC} = 1.8 V$

Table 6: Electrical Characteristics: Microphone Bias

| Description | Condition | Min | Тур | Max | Unit |
|------------------------------|---|----------|-----|-----|-------------------|
| Programmable output voltage | No load, V _{DD_MIC} > V _{MICBIAS} + 200 mV | 1.6 | | 3.0 | V |
| Output voltage step | | | 200 | | mV |
| Output current | Output voltage droop < 50 mV | 2 | | | mA |
| Power supply rejection ratio | 20 Hz to 2 kHz 2 kHz to 20 kHz | 70 50 | | | dB |
| Output voltage noise | V _{MICBIAS} ≤ 2.2 V | | 5 | | μV _{RMS} |

Datasheet

9 Functional Description

DA7217 is a high-performance, low-power audio codec optimized for use in headsets or wearable devices.

It contains two analog microphone-to-ADC and/or up to four digital microphone-to-input filter paths, and a DAI for input and output.

DA7217 has differential headphone outputs for use inside headset devices, offering excellent left to right channel separation and common mode noise rejection. The other chip in this family, the DA7218, has single-ended headphone outputs, and has been designed with headphone-detect for use in accessories.

The digital engine input includes a high pass filter, automatic level control (ALC), and level detection. The output stage has a high pass filter, a 5-band EQ, and a 5-stage biquad filter.

The digital engine also has a dynamic range extension (DRE) block, and a tone generator that supports dual tone multi-frequency (DTMF).

The flexible digital mixer allows any or all of the seven inputs (four input filters, the tone generator, and DAI left and right inputs) to be routed to any or all of the six digital outputs (left and right output filters, and DAI outputs). There is an independently programmable gain on each of the 42 possible paths.

9.1 Device Operation

9.1.1 Power Modes

The DA7217 codec has two operating modes:

STANDBY – The device is asleep with all internal circuits disabled, but all register states are retained.

ACTIVE – The device is awake and ready to perform audio functions. Blocks can be enabled as required.

9.1.1.1 STANDBY Mode

In STANDBY mode, both the reference voltage generator and the reference oscillator are shut down so no audio functions are possible. All audio paths must be shut down before entering STANDBY mode (system_active = 0), as the transition to STANDBY mode is immediate and is not pop-free.

9.1.1.2 ACTIVE Mode

To put the device in ACTIVE mode, write system_active = 1. On entering ACTIVE mode, the reference voltage generator and reference oscillator are automatically enabled.

9.2 Input Paths

9.2.1 Microphone Inputs

The DA7217 analog inputs consist of two independent signal chains, each including two amplifiers and an ADC as shown in Figure 7.

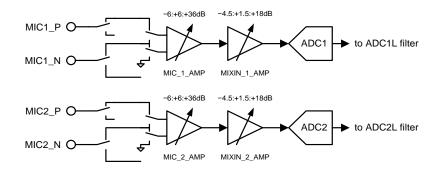

Figure 7: Analog Inputs Block Diagram

The two microphone amplifiers can be configured in

- fully differential mode for improved common-mode noise rejection
- pseudo-differential mode
- single-ended mode (MIC1|2_P or MIC1|2_N)

All configurations are illustrated in Figure 8.

Digital microphone connection details are described in section 9.2.1.3.

9.2.1.1 Microphone Biases

The DA7217 codec has two independently controlled microphone bias outputs.

Low Noise (Normal) Mode

Each bias output can be independently programmed from 1.6 V to 3.0 V in 0.2 V steps using micbias_1_level and micbias_2_level in MICBIAS_CTRL.

Each microphone bias level can only be changed while the associated MICBIAS circuit is disabled (micbias_1_en = 0 for MICBIAS1 or micbias_2_en = 0 for MICBIAS2).

Low-Power Mode

Both microphone bias circuits can also be used as low-power voltage sources optimized for always-on microphones. In low-power mode the output voltage is fixed at 1.2 V. Low-power mode is enabled by setting the micbias_1_lp_mode = 1 in the MICBIAS_CTRL register.

MICBIAS1 is enabled by setting micbias_1_en = 1.

The second microphone bias circuit (MICBIAS2) is controlled in the same way.

Low-power mode can only be changed while the MICBIAS circuits are disabled (micbias_1_en = 0 for low-power mode on MICBIAS1, and micbias_2_en = 0 for low-power mode on MICBIAS2).

| micbias_1_level micbias_2_level | Output Voltage in Low-Noise Mode micbias_1 2_lp_mode = 0 (V) | Output Voltage in Low-Power Mode micbias_1 2_lp_mode = 1 (V) |

DA7217

Ultra-Low Power Stereo Codec

9.2.1.2 Microphone Amplifier

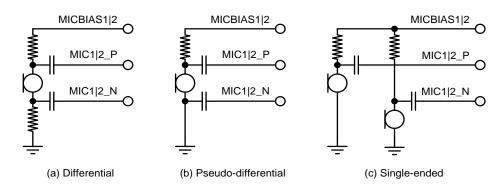

Figure 8: Analog Microphone Configurations

The configuration of the first microphone amplifier (MIC_1_CTRL) is specified using mic_1_amp_in_sel. It is enabled by setting mic_1_amp_en = 1, and is muted by setting mic_1_amp_mute_en = 1.

The gain of the amplifier can be set in the range of -6 dB to +36 dB in 6 dB steps using mic_1_amp_gain (see Table 26 :).

The second microphone amplifier (MIC_2_CTRL) is controlled in the same way.

| mic_1_amp_gain mic_2_amp_gain | Amplifier Gain (dB) |
|----------------------------------|---------------------|
| 000 | -6 |
| 001 | 0 |
| 010 | 6 |
| 011 | 12 |
| 100 | 18 |
| 101 | 24 |
| 110 | 30 |
| 111 | 36 |

Table 26 : MIC_1_GAIN and MIC_2_GAIN Gain Settings

9.2.1.3 Digital Microphones

The DA7217 can support up to four digital microphones by reusing the MIC1_P and MIC_2P pins as clock outputs, and the MIC1_N and MIC_2N pins as digital data inputs.

The IO voltage level of DMIC1 is set by the voltage present on MICBIAS1 and the IO voltage level of DMIC2 is set by the voltage present on MICBIAS2. This voltage can be either an output of the MICBIAS LDO or, for minimum power consumption, the IO voltage of the DMIC can be connected as an input on the appropriate MICBIAS pin.

The first DMIC input is controlled using the DMIC_1_CTRL register. The left channel is enabled using dmic_11_en and the right channel using dmic_1r_en. The DMIC clock rate can be set using dmic_1_clk_rate.

DMIC_1 data is sampled on both the rising and the falling edges of the DMIC clock. The register field dmic_1_data_sel determines which of the rising and the falling edges corresponds to the left channel, and which to the right.

The register field dmic_1_samplephase controls whether the sample point for the DMIC data is on the DMICCLCK edges (dmic_1_samplephase = 0) or at the midpoint between the DMICCLCK edges (dmic_1_samplephase = 1).

The second DMIC input is controlled in the same way using DMIC_2_CTRL.

| Function | Degister Dite | Bit Setting | | | |
|--|--|--|--|--|--|
| Function | Register Bits | 0 | 1 | | |
| Digital microphone enable/disable | dmic_1r_en dmic_1I_en dmic_2I_en dmic_2r_en | DMIC is disabled | DMIC is enabled | | |
| Digital microphone clock rate | dmic_l_clk_rate dmic_2_clk_rate | 3.072 MHz or 2.8224 MHz | 1.536 MHz or 1.4112 MHz | | |
| Digital microphone sample phase | dmic_1_samplephase dmic_2_samplephase | Data sampled on the clock edges | Data sampled between the clock edges | | |
| Digital microphone left/right data selection | dmic_1_data_sel dmic_2_data_sel | Rising edge = left Falling edge = right | Rising edge = right Falling edge = left | | |

9.2.1.4 Input Amplifiers

The two input amplifiers provide an additional gain stage between the microphone amplifiers (see section 9.2.1.2 and Figure 7) and the ADC inputs. The input amplifier ($MIXIN_1_CTRL$) is enabled by setting mixin_1_amp_en = 1.

The gain can be set in the range of -4.5 dB to +18 dB in 1.5 dB steps using MIXIN_1_GAIN. It is recommended that gain updates be ramped through all intermediate values by setting mixin_1_amp_ramp_en = 1. This ramp setting overrides the settings of mixin_1_amp_zc_en.

As an alternative to zero-cross synchronization, gain updates can be synchronized with signal zerocrossings by setting $mixin_1_amp_zc_en = 1$. If no zero-crossing is detected within the timeout period of approximately 100 ms, the update is applied unconditionally.

The amplifier can be muted using mixin_1_amp_mute_en.The single input to the first amplifier can be deselected by setting mixin_1_mix_sel = 0.

The second input amplifier (MIXIN_2_CTRL) is controlled in the same manner as MIXIN_1_CTRL.

9.2.2 Analog to Digital Converters

The DA7217 codec contains the stereo audio analog to digital converters (ADCs). These can run either in low-power mode for always-on applications, or in high performance mode for other applications.

Each ADC is automatically enabled whenever the input filters are enabled and digital microphones are not enabled.

Not all sample rates are supported in all modes. Table 29 describes which sample rates are supported in each mode.

| Sample Rate (kHz) | Low Pow adc_lp_n | | Normal Mode adc_lp_mode = 0 | | | |
|-------------------|-------------------------------|---------------|--------------------------------|--------------|--|--|
| | voice_en = 1 | voice_en = 0 | voice_en = 1 | voice_en = 0 | | |

| 88.200/96.0 | Not supported | Not supported | Not supported | Supported | | |

Table 29: Supported Sample Rates in Different Modes

9.2.2.1 High Performance Mode

In normal (high performance) mode ($adc_lp_mode = 0$), the ADCs are clocked at a fixed rate of either 3.072 MHz or 2.8224 MHz, depending on the required input sample rate (SR1).

9.2.2.2 Low-Power Mode

The low-power mode of operation is designed for always-on applications. In low-power mode, the ADCs are clocked at half the 'normal' (high-performance) rate, that is, at either 1.5360 MHz or 1.4112 MHz. Low-power mode is set in both ADCs by setting $adc_lp_mode = 1$. In this mode there is a small increase in distortion.

9.2.2.3 Anti-Alias Filters

The anti-alias filters at the front-end of the ADC are enabled by default. The anti-alias filters can be disabled to save power by setting $adc_1_aaf_en = 0$ for channel 1, or $adc_2_aaf_en = 0$ for channel 2.

9.3 Digital Engine

The DA7217 chip contains a digital engine that performs the signal processing and also provides overall system control. Within the digital engine, all seven possible input signals can be mixed and output to any of the six possible outputs. See Figure 9 for a visual representation of this.

The output signals from either of the two ADCs or any of the four digital microphones are passed to the input filter block. The filter block includes a high-pass filter for wind noise suppression, an automatic level control, and input level detection.

The signals from the input filters are sent to the digital mixer where they can be combined with signals from the tone generator and the DAI, and routed to the output filters and the DAI. The output filters contain a high-pass filter for DC offset removal, a fixed 5-band equalizer, and a flexible 5-stage biguad filter to adjust the sound of the output signals.

There is also a sidetone path that can take one signal from either the ADCs or the digital microphones and perform filtering using three biquad sections before passing the signal straight to the output filters.

The digital engine contains a DRE module that can be used to automatically swap analog and digital gains on the input and output signal paths in order to maximize the dynamic range of the codec.

Finally a system controller module is included to ensure correct sequencing of the events required to bring up and shut down signal paths without creating pops and clicks.

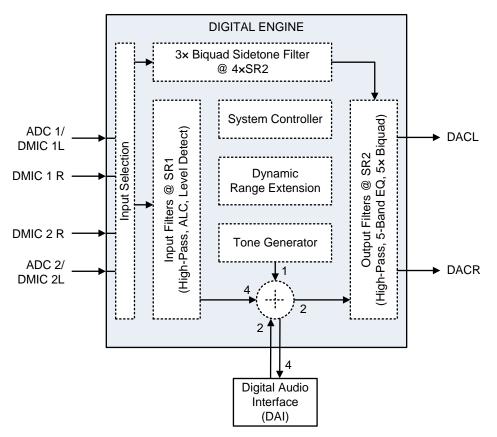

Figure 9: Digital Engine Block Diagram

9.3.1 Input Processing

9.3.1.1 Input Filters

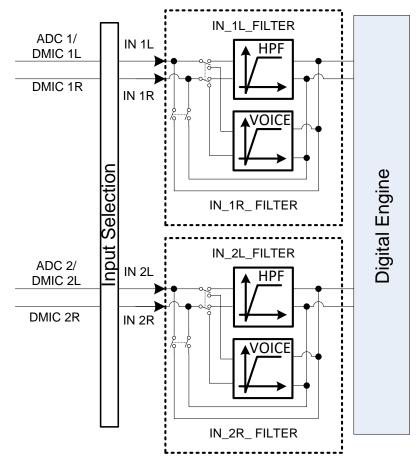

Figure 10: Input Filters Block Diagram

There are two stereo pairs of input filters (IN_1L_FILTER_CTRL and IN_1R_FILTER_CTRL, and IN_2L_FILTER_CTRL and IN_2R_FILTER_CTRL) that can be used to process signals from either the two mono ADCs, or from the two stereo digital microphone inputs. The input (ADC or DMIC) to the input filters is selected using dmic_1l_en (or dmic_1r_en) and dmic_2l_en (or dmic_2r_en).

If an ADC input is selected, the analog part of the ADC is enabled whenever the DMIC has not been enabled and the connected input filter has been enabled using one of the filter enabling bits (in_11_filter_en, in_1r_filter_en, in_21_filter_en, and in_2r_filter_en).

Left and right channels of the two input filters can be controlled independently. The left channel of the first input filter is enabled using in_11_filter_en. It is muted using in_11_mute_en and gain-ramping is enabled using in_11_ramp_en. The gain can be set in the range of -83.25 dB to +12 dB in +0.75 dB steps using in_11_digital_gain.

The right channel and the second input filter channels are all controlled in the same way.

9.3.1.2 High-Pass Filter

The DA7217 contains two stereo input high-pass filters (HPFs). The first filter is controlled using IN_1_HPF_FILTER_CTRL and IN_2_HPF_FILTER_CTRL to remove any DC components from the incoming audio. This filter operates at all sample rates. For this first filter, in music mode in_1_voice_en must be set to 0 and the HPF corner frequency is set using in_1_audio_hpf_corner.

A second high pass filter is available when the sample rate is 32 kHz or lower for voice filtering. This filter is controlled using in_1_voice_en and in_2_voice_en. It has a wider range of corner frequencies to help remove low frequency artefacts such as wind noise.

In voice mode, in_1_voice_en must = 1 in which case the HPF corner frequency is set using in_1_voice_en.

The value of the HPF corner frequency also depends on the input sample rate (SR1) as shown in Table 31 (ADC in high power mode) and Table 32 (ADC in low power mode). Note that when operating in ADC low power mode ($adc_lp_mode = 1$), the voice filter is only available at a sample rate of 8 kHz. Similarly the audio filter will not operate at sample rates of 32 kHz, 88.2 kHz, or 96 kHz.

The sample rates available in the different ADC power modes are summarized in Table 31 for the ADC in high-power mode ($adc_lp_mode = 0$), and Table 32 for the ADC in low-power mode ($adc_lp_mode = 1$).

9.3.1.3 Automatic Level Control

For improved sound recordings of signals with a large volume range, the DA7217 offers a fullyconfigurable automatic recording level control (ALC) for microphone inputs. This is enabled via the ALC_CTRL1, and can be enabled independently on any of the four input channels. The ALC monitors the digital signal after the ADC and adjusts the microphones' analog and digital gain to maintain a constant recording level, regardless of the analog input signal level.

Operation of ALC is illustrated in Figure 11. When the input signal volume is high, the ALC system will reduce the overall gain until the output volume is below the specified maximum value. When the input signal volume is low, the ALC will increase the gain until the output volume increases above the specified minimum value. If the output signal is within the desired signal level (between the specified minimum and maximum levels), the ALC does nothing.

The minimum and the maximum thresholds that trigger a gain change of the ALC are programmed by the alc_threshold_min and alc_threshold_max controls.

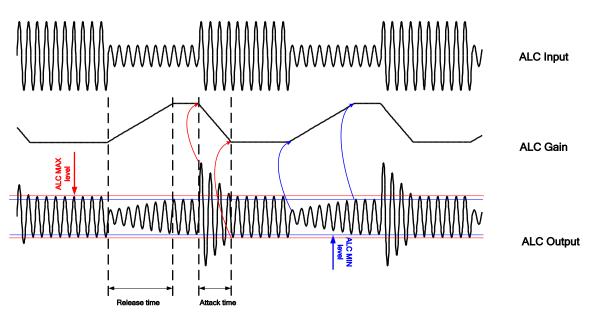

Figure 11: Principle of Operation of the ALC

The ALC can operate in two modes; Digital-Only mode and Hybrid (combined analog and digital gain) mode.

In Digital-Only mode only the digital gain in the ADC is altered. Note that although the ALC is controlling the gain, it does not modify any of the registers in_1l_digital_gain, in_1r_digital_gain, in_2l_digital_gain, or in_2r_digital_gain. These registers are ignored while the ALC is in operation. The minimum and maximum levels of digital gain that can be applied by the ALC are controlled using alc_atten_max and alc_gain_max.

When using analog microphones, Hybrid mode can be enabled using alc_sync_mode. See section 9.3.1.5 for details on ALC calibration in Hybrid mode.

In Hybrid mode, the total gain is made up of an analog gain (which is applied to the microphone amplifiers) and a digital gain, (which is implemented in the filtering stage). The ALC block monitors and controls the gain of the microphone and the ADC. Note that although the ALC is controlling the gain, it does not modify any of the registers mixin_1_amp_gain or mixin_2_amp_gain, nor does it modify any of the digital gain registers in_11_digital_gain, in_1r_digital_gain, in_21_digital_gain, or in_2r_digital_gain. These registers are ignored while the ALC is in operation.

| Dataa | haat |
|-------|------|
| Datas | neet |
| Parao | |

Similarly the minimum and maximum levels of analog gain are controlled by alc_ana_gain_min and alc_ana_gain_max. The rates at which the gain is changed are defined by the attack and decay rates in register ALC_CTRL2. When attacking, the gain decreases with alc_attack rate. When decaying, the gain increases with alc_release rate.

Hybrid mode should be used whenever analog microphones are being used. Digital-Only mode should be used whenever digital microphones are being used.

The hold-time is defined by alc_hold in the ALC_CTRL3 register. This controls the length of time that the system maintains the current gain level before starting to decay. This prevents unwanted changes in the recording level when there is a short-lived 'spike' in input volume, for example when recording speech.

Typically the attack rate should be much faster than the decay rate. To avoid clipping it is necessary to reduce rapidly increasing waveforms as quickly as possible, whereas fast release times will result in the signal appearing to 'pump'. The ALC also has an anti-clip function that applies a very fast attack rate when the input signal is close to full-scale. This prevents clipping of the signal by reducing the signal gain at a faster rate than would normally be applied. The anti-clip function is enabled using alc_anticlip_en, and the trigger threshold is set in the range 0.034 dB/Fs to 0.272 dB/Fs using alc_anticlip_step.

A recording noise-gate feature is provided to avoid increasing the gain of the channel when there is no signal, or when only a noise signal is present. Boosting a signal on which only noise is present is known as 'noise pumping', the noise-gate prevents this. Whenever the level of the input signal drops below the noise threshold configured in alc_noise, the channel gain remains constant.

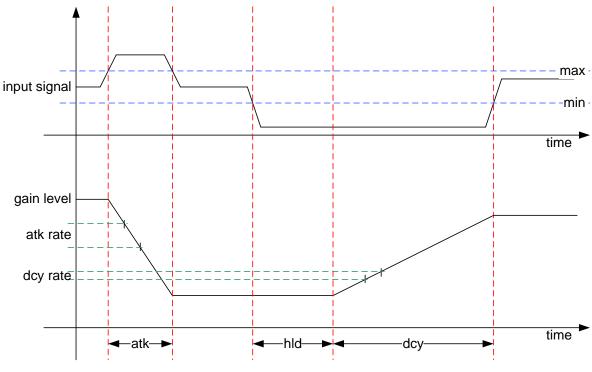

Figure 12: Attack, Delay and Hold Parameters

9.3.1.4 Input Dynamic Range Extension

When using analog microphones, the input dynamic range extension (DRE) automatically swaps the analog and digital gains to maximize the dynamic range at all times.

| D - | tas | | - 4 |
|------------|------|----|-----|
| 112 | Tac | ne | OT. |
| Du | La S | | |

The DRE block, like the Hybrid-mode ALC, controls both the analog MICAMP gain and the digital gain. However it applies equal and opposite adjustments to analog and digital gains so that total path gain remains constant while the input dynamic range is increased.

DRE can be enabled for either or both ADCs using the ags_enable bits. The trigger level for the DRE can be set in the range of -90 dB to 0 dB in 6 dB steps using ags_trigger. The maximum attenuation that can be applied by the DRE can be set in the range of 0 dB to 36 dB in 6 dB steps using ags_att_max. There is also a timeout of 0.1 s that can be enabled using ags_timeout_en, and a mechanism to prevent clipping that can be enabled using ags_anticlip_en. Note that the input DRE cannot be used with ALC. Only one of these functions can be used at any one time.

9.3.1.5 Automatic Level Control and Input Dynamic Range Extension Calibration

When using the ALC in Hybrid mode or when using the input DRE, the DC offset at the output of the MICAMPs must be compensated for to prevent audible effects when the gains are changed. This compensation is performed automatically if the following sequence is followed:

- 1. Enable the required MICAMP(s) unmuted.
- 2. Mute the MICAMP(s). Note that it is important to enable the MICAMPS unmuted before using them in this step.
- 3. Enable the required MIXIN_1|2_AMP(s) and ADC(s) unmuted.
- 4. Enable the DAI or set the PC to Freerun mode.
- 5. Set calib_auto_en to 1 to start the calibration. This bit will clear to 0 once the calibration is complete.
- 6. Set calib_offset_en to 1.
- 7. Enable the ALC in Hybrid mode or the DRE. Note that ALC and input DRE are mutually exclusive, and only one should be enabled at any one time.
- 8. Unmute the MICAMP(s).

9.3.1.6 Level Detection

Level detection can be used to signal to the host processor (via the nIRQ pin) that the input signal has exceeded the threshold level determined by lvl_det_level. Level detection can be enabled on any or all of the four input filter channels using the lvl_det_en bits.

The threshold used for level detection can be programmed in the range of 1/128 full-scale to full-scale using lvl_det_level.

9.3.2 Sidetone Processing

There is a mono, low-latency filter channel between inputs and outputs for implementing a sidetone path. The input signal to any one of the four input channels (from DMIC or ADC) can also be routed to the sidetone channel using sidetone_in_select.

The output from the sidetone channel can be added to left or right (or both) output filters using outfilt_st_1l_src and outfilt_st_1r_src.

The sidetone filter itself contains a three-stage biquad filter that can be used to provide custom filtering of the input signal.

The biquad filter also has a programmable gain stage to adjust the level of the sidetone signal. This is controlled by sidetone_gain, and provides gain in the range -42 dB to +4.5 dB in 1.5 dB steps.

The sidetone path is enabled using sidetone_filter_en. and muted using sidetone_mute_en.

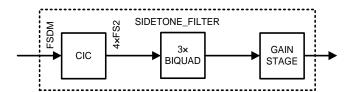

Figure 13: Sidetone Filter Block Diagram

Datasheet

Revision 3.3

The sidetone biquad filter can be used to provide custom filtering, for example microphone frequency response. Each of the three biquad stages has five 16-bit coefficients a0, a1, a2, b1 and b2 (see Figure 21). For the three stages, the coefficients are numbered a00, a01 etc. as shown in Figure 14:

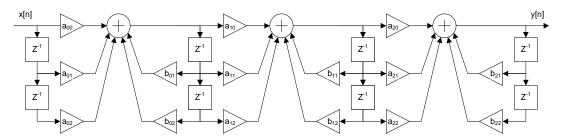

Figure 14: Cascade of Three Biquad Filter Stages

The coefficients are stored using 8-bit registers in a dedicated address space. They are programmed by first writing the coefficient data value to sidetone_biq_3stage_data and then the coefficient address to sidetone_biq_3stage_addr. The address location for each of the coefficients is described in Table 33: Each of the 16-bit coefficients is two's complement values that are programmed in the range of -2 (0x8000) to +2 (0x7FFF). It is the responsibility of the user to ensure that filter transfer function corresponding to the programmed coefficients is stable.

Datasheet

9.3.3 Tone Generator

The tone generator contains two independent Sine Wave Generators (SWGs). Each SWG can generate a sine wave at a frequency (FREQ) from approximately 1 Hz to 12 kHz according to the programmed 16-bit value:

- FREQ[15:0] = 2¹⁶ * f_{SWG}/12000, for SR2 = (8, 12, 16, 24, 32, 48,96) kHz
- FREQ[15:0] = 2¹⁶ * f_{SWG}/11025, for SR2 = (11.025, 22.05, 44.1, 88.2) kHz

The DA7217 should not be programmed with frequency greater than the Nyquist frequency.

Nyquist frequency = SR2/2

For the first SWG, the FREQ value is stored in two 8-bit registers as freq1_u = FREQ[15:8] and freq1_l = FREQ[7:0]. The second SWG frequency is programmed in the same way using freq2_u and freq2_l. The output of the tone generator can come from either of the SWGs, or from a combination of both of them as specified by swg_sel. In addition the tone generator can produce standard Dual Tone Multi-Frequency (DTMF) tones using the two SWGs if dtmf_en = 1 and the required keypad value is programmed in dtmf_reg as shown in Table 34.

| | SWG1 Frequency (Hz) | | | | | | |
|----------------|---------------------|------|---------|------|--|--|--|
| SWG2 Freq (Hz) | 1209 | 1336 | 1477 | 1633 | | | |
| 697 | 0x1 | 0x2 | 0x3 | 0xA | | | |
| 770 | 0x4 | 0x5 | 0x6 | 0xB | | | |
| 852 | 0x7 | 0x8 | 0x9 | 0xC | | | |
| 941 | 0xE (*) | 0x0 | 0xF (#) | 0xD | | | |

Table 34: DTMF Tones Corresponding to dtmf_reg Value

The tone generator can produce 1, 2, 3, 4, 8, 16, or 32 beeps, or a continuous beep, as determined by beep_cycles. Each beep has an on period from 10 ms to 2 s as programmed in beep_on_per and an off period from 10 ms to 2 s as programmed in beep_off_per. The tone generator is started by setting the start_stopn bit, and is halted by clearing this bit. If start_stopn is cleared, the tone generator stops at the completion of the current beep cycle or at the next zero-cross if the number of beeps is set to continuous (beep_cycles = 110 or = 111). The start_stopn bit is automatically cleared once the programmed number of beep cycles has been completed.

The tone generator can also be used to produce an S-ramp by setting swg_sel to 0x03. System Controller

The system controller (SC) automates the sequencing of the multiple blocks required to set up one or more particular audio paths. It is an optional feature, and operates by performing register writes with optimal sequencing and timing, thus eliminating pops and clicks.

The inputs are controlled using SYSTEM_MODES_INPUT, and the outputs are controlled using SYSTEM_MODES_OUTPUT. Writing to the mode_submit field of either of these registers will cause the system controller (SC) to process both input and output paths.

When the SC is activated by asserting the mode_submit field, all of the register-writes that are required by the selected sub systems are performed automatically. Each sub-system is brought up, or down, in the correct order to avoid pops and clicks. In addition, within each sub system, the component parts are brought up in the correct pop-free and click-free sequence.

9.3.4 Output Processing

9.3.4.1 Output Filters

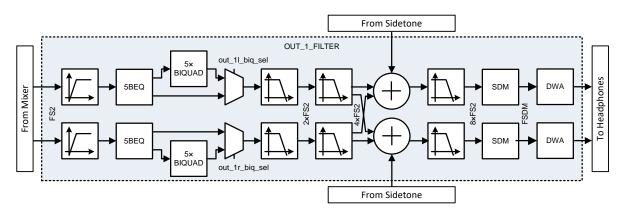

Figure 15: Output Filters Block Diagram

There is a stereo output filter chain that is used to process signals to be sent to the stereo DAC. The signals from the digital mixer (at SR2 rate) can be processed through a high-pass filter, a fixed 5-band equalizer and a 5-stage biquad filter. They can also be combined with signals from the sidetone filter (at 4 * SR2 rate).

Left and right channels of the output filter can be controlled independently. The left channel of the output filter is enabled using out_11_filter_en and is muted using out_11_mute_en. Gain ramping is enabled using out_11_ramp_en.

If out_1I_subrange_en is also set, the ramping process will step though much finer gain increments. The 5-stage biquad filter is selected using out_1I_biq_5stage_sel. The gain of the left channel can be set in the range of -83.25 dB to +108 dB in 0.75 dB steps using OUT_1L_GAIN.

The right channel of the output filter is controlled in the same way.

9.3.4.2 High-Pass Filter

The output high-pass filters (HPFs) are controlled using OUT_1_HPF_FILTER_CTRL. In music mode out_1_voice_en must be set to 0 and the HPF corner frequency is set using out_1_audio_hpf_corner. In voice mode, out_1_voice_en must be set to 1, in which case the HPF corner frequency is set using out_1_voice_hpf_corner.

The value of the HPF corner frequency also depends on the output sample rate (SR2) as shown in Table 35.

The right channel of the HPF is controlled in the same way.

Datasheet

9.3.4.3 5-Band Equalizer

The output filters can provide gain or attenuation in each of five separate (fixed) frequency bands using the 5-band equalizer (EQ). The equalizer, for both left and right channels, is enabled using out_1_eq_en.

The gain or attenuation of the first frequency band is programmable from -10.5 dB to 12.0 dB in 1.5 dB steps using out_1_eq_band1. The other four bands are programmable in the same way using out_1_eq_band2, out_1_eq_band3, out_1_eq_band4, and out_1_eq_band5. The center or cut-off frequency of each of the five bands depends on the output sample rate (SR2) as shown in Table 37.

The 5-band EQ and the 5-band biquad filter can be used at the same time for greater filtering control.

Table 37: Output 5-band Equalizer Centre and Cut-Off Frequencies

For equalizer bands 1 and 5, the cut-off frequency depends on the gain setting. The figures quoted in this table refer to the -1 dB point with the band gain set to -3 dB

| 600 | Center/Cut-Off Frequency (Hz) at Programmed Setting | | | | | | | |
|--------------|---|------------------|------------------|------------------|-------------------|--|--|--|

NOTE

The 5-band equalizer is only available for sample rates up to 48 kHz. The frequency response of the 5-band equalizer at sample rate of 48 kHz is shown graphically in Figure 16 to Figure 20:

The cut-off for equalizer bands 1 and 5 is dependent on gain setting. The figures quoted in Table 37 refer to the -1 dB point with the band gain set to -3 dB

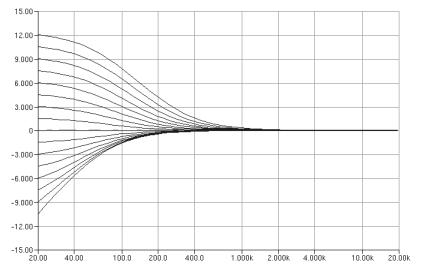

Figure 16: Equalizer Filter Band 1 Frequency Response at FS = 48 kHz

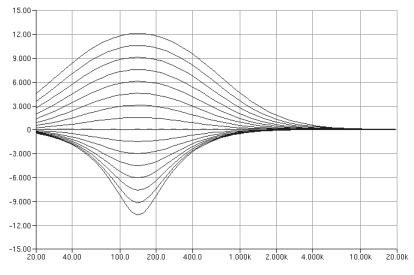

Figure 17: Equalizer Filter Band 2 Frequency Response at FS = 48 kHz

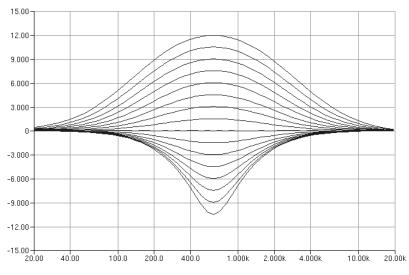

Figure 18: Equalizer Filter Band 3 Frequency Response at FS = 48 kHz

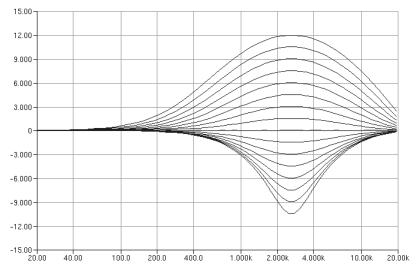

Figure 19: Equalizer Filter Band 4 Frequency Response at FS = 48 kHz

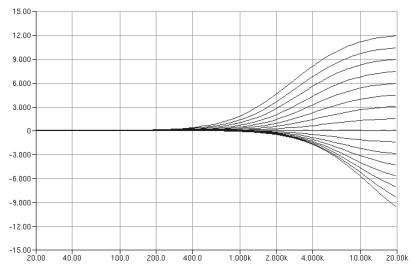

Figure 20: Equalizer Filter Band 5 Frequency Response at FS = 48 kHz

9.3.4.4 5-Stage Biquad Filter

The stereo 5-stage biquad filter can be used to provide more flexible filtering of the output signal than can be achieved using the 5-band equalizer. The biquad filters can be used for the implementation of low-pass, high-pass or notch filters.

The 5-band EQ and the 5-band biquad filter can be used at the same time for greater filtering control.

The biquad filter is enabled using out_1_biq_5stage_filter_en and can be muted using out_1_biq_5stage_mute_en.

The biquad filter on each channel can be selected independently using out_1I_biq_5stage_sel and out_1r_biq_5stage_sel in the OUT_1L_FILTER_CTRL and OUT_1R_FILTER_CTRL registers.

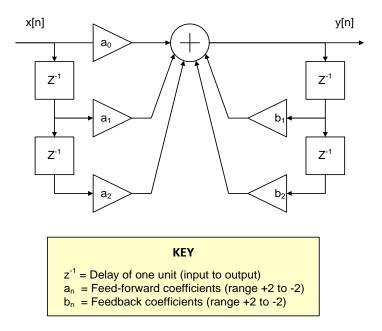

Figure 21: Single Biquad Filter Stage

Each of the five biquad stages has five 16-bit coefficients a0, a1, a2, b1 and b2 as shown in Figure 21. For the five stages the coefficients are numbered a00, a01 and so on as shown in Figure 22.

The filter sections are implemented using a direct form one architecture which implements the transfer function shown in Figure 21:

$$H(z) = \frac{a_0 + a_1 z^{-1} + a_2 z^{-2} + a_3 z - 3 + a_4 z - 4}{1 - b_1 z^{-1} - b_2 z^{-2}}$$

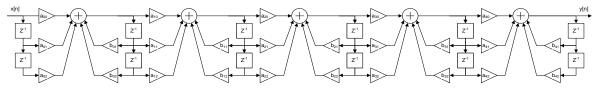

Figure 22: Cascade of Five Biquad Filter Stages

The biquad filters in both left and right channels share the same set of coefficients.

Each of the coefficients is stored using two 8-bit registers in a dedicated address space. All of the coefficients are programmed by first writing the coefficient data value to OUT_1_BIQ_5STAGE_DATA and then the coefficient address to OUT_1_BIQ_5STAGE_ADDR. The address location for each of the coefficients is described in Table 38.

Each of the 16-bit coefficients are two's complement values that can be programmed in the range of -2 (0x8000) to +2 (0x7FFF(0)). Checks should be made to ensure that the pre-programmed coefficients result in a stable transfer filter function.

The full numeric range of the coefficients is -2 to +1.999938964843750.

9.3.4.5 Output Dynamic Range Extension

The output dynamic range extension (DRE) block extends the range of the DA7217.

DRE can be enabled on either left, right or both output channels using dgs_enable. The input signal level at which the DRE starts swapping gains can be set in the range of -90 dB to 0 dB in 6 dB steps using dgs_signal_lvl. To prevent clipping, the input signal level at which all of the applied DRE steps are removed can be set in the range of -42 dB to 0 dB in 6 dB steps using dgs_anticlip_lvl. The maximum number of 1.5 dB gain steps that the DRE is allowed to apply can be controlled using dgs_steps.

The response time of the leaky integrator used to track the signal level at the input of the DRE is determined by the fraction of the signal added at each step. The fall rate is set by the fraction added when the signal is smaller than the current average, which can be programmed in the range 1/65536 to 1/4 using dgs_fall_coeff. The rise rate is set by the fraction added when the signal is larger than the current average, which can be programmed in the range 1/16384 to 1 using dgs_rise_coeff.

Ramping of any changes in gain levels is enabled by setting dgs_ramp_en = 1. When ramping is being performed, the changes in gain are made in 1.5 dB steps, with the maximum number of 1.5 dB steps controlled by dgs_steps.

Finer control of the ramping steps is provided if dgs_subr_en = 1. If dgs_subr_en = 1, each gain change of 1.5 dB is performed in smaller steps.

It is possible to disable the ramping of the 1.5 dB gain steps by setting dgs_ramp_en = 0, and similarly it is possible to disable the sub-ranging between the 1.5 dB gain steps by setting dgs_subr_en = 0. Note that clearing either of these two bits is likely to produce unacceptable audio artefacts such as pops and clicks.

9.3.4.6 DAC Noise Gate

The DAC noise gate can be used to automatically mute the outputs when the average signal level at the output of both left and right channel DACs falls below a programmed noise threshold for longer than a programmed hold time.

The DAC noise gate is enabled using dac_ng_en. The threshold below which the noise gate is activated can be set in the range of -102 dB to -60 dB in 6 dB steps using dac_ng_on_threshold. The

| _ | _ |
|-------|-------|
| Datac | hoot |
| Datas | neer |
| Pulus | IICCL |

threshold above which the noise gate deactivates can be set in the same range using dac_ng_off_threshold.

It is recommended to set dac_ng_off_threshold > dac_ng_on_threshold to provide some hysteresis.

The number of samples for which the DAC output signal must be below the on-threshold before the noise gate is activated can be set to 256, 512, 1024 or 2048 using dac_ng_setup_time. The noise gate is deactivated as soon as the signal level rises above the off threshold.

Prior to muting the output the gain is ramped down to minimum, and after un-muting the output the gain is ramped back up to its original value. The ramp rates can be adjusted using dac_ng_rampdn_rate and dac_ng_rampup_rate.

9.3.4.7 Digital Mixer

The DA7217 codec contains a flexible digital mixer. Any or all of the seven digital inputs (four input filters, one tone generator, and two DAI inputs) can be routed to any or all of the six digital outputs (Output Filter 1 and Output Filter 2, and four DAI outputs) with a programmable gain on each of the 42 possible paths.

The names of the registers that specify the data source, and the data output, take the form '<output target short name>_src'. Each of these 7-bit registers uses one of its bit positions to select a signal source. These registers and the bit positions corresponding to each of the seven possible signal source are listed in Table 39.

Example: Setting outdai_11_src[2] = 1 selects source data from Input Filter 2L (determined by bit position [2]) and passes it to Output DAI 1L.

The gain on each of the 42 signal paths (seven possible inputs to six possible outputs) are independently controllable using registers whose names take the form

`<output target short name>_<input source short name>_gain'. These register fields are listed in Table 40. Every register field uses the same set of settings to provide a gain range of -42 dB to 4.5 dB in -1.5 dB steps. The full set of possible gain settings for each register is listed in Table 41.

Example: Setting outdai_1l_infilt_2r_gain = 01001 provides -28.5 dB gain on the signal path Input Filter 2L to Output DAI 1L.

See Figure 23.for the input-to-output paths

Table 41: Gain Settings and Values for all Registers Listed in Table 40

9.3.4.8 Digital Gain

Input Channel Gain

The four input filter channels can be set to apply gain in the range of -83.25 dB to +12 dB in 0.75 dB steps by programming in_1l_digital_gain, in_1r_digital_gain, in_2l_digital_gain, and in_2r_digital_gain.

Output Channel Gain

The two output filter channels can be set to apply gain in the range of -83.25 dB to +108 dB in 0.75 dB steps by programming out_1l_digital_gain and out_1r_digital_gain.

9.4 Output Paths

9.4.1 Digital to Analog Converter

The DA7217 codec includes a stereo audio digital to analog converter (DAC). Left and right channels of the DAC are independently and automatically enabled whenever the corresponding output filter channel is enabled.

The DAC is clocked at 3.072 MHz or 2.8224 MHz depending on the output sample rate (SR2). Left and right channels of the DAC are independently and automatically enabled whenever the corresponding output filter channel is enabled.

9.4.2 Headphone Amplifiers

Each headphone path has one finely adjustable amplifier (MIXOUT_L_GAIN and MIXOUT_R_GAIN) providing a gain of -1.0 dB to 0 dB in 0.5 dB steps. These are followed by a more powerful headphone amplifier stage providing a gain of -57 dB to +6 dB in 1.5 dB steps. Together they provide a total gain range of -58 dB to +6 dB in 0.5 dB steps.

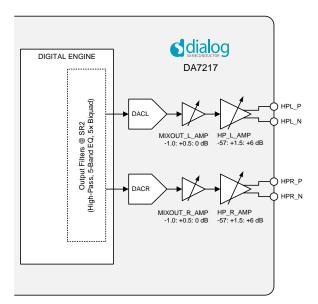

Figure 24: Headphone Output Paths

The left-channel amplifier (MIXOUT_L_CTRL) is enabled by setting mixout_l_amp_en = 1. The gain can be set in the range of -1.0 dB to 0 dB in 0.5 dB steps using mixout_l_amp_gain. This setting is static and is not synchronized with signal zero crossings and cannot be ramped. This amplifier is used to fine tune the overall analog gain level in the DAC to headphone path. The right channel output buffer (MIXOUT_R_CTRL) is controlled in the same manner.

The two finely adjustable amplifiers MIXOUT_L_GAIN and MIXOUT_R_GAIN offer no mixing capabilities. They allow additional fine-tuning of the gain on the headphone outputs from -1.0 dB to 0 dB in 0.5 dB steps.

The amplifiers are configured to operate differentially. The headphone loads are connected between HPL_P and HPL_N for the left headphone, and between HPR_P and HPR_N for the right.

The mode in which the headphone amplifiers operate is controlled using the HP_DIFF_CTRL register. The hp_amp_diff_mode_en bit **must** be set to 1 (for differential mode). The default setting of 0 is not supported in this device.

The headphone amplifiers can operate in either single-supply mode (no charge pump) or true-ground (charge pump) mode.

The supply mode can be set using hp_amp_single_supply_en. Single-supply mode is achieved by connecting HPCSP to VDD and HPCSN to GND on the PCB, and setting hp_amp_single_supply_en

| D | 4 | 4 |
|----|-----|----------|
| Da | tas | neet |

01-Feb-2019

DA7217

Ultra-Low Power Stereo Codec

to 1. This register bit is protected to prevent accidental damage to the device and must be unlocked by writing 0xC3 to HP_DIFF_UNLOCK.

The left-channel headphone amplifier (HP_L_CTRL) is enabled by setting hp_l_amp_en = 1. The output stage is enabled independently by setting hp_l_amp_oe = 1.

The amplifier gain can be set in the range of –57 dB to +6 dB in 1.5 dB steps using hp_l_amp_gain.

Gain updates can be ramped through all intermediate values by setting $hp_l_amp_ramp_en = 1$. This ramp setting overrides the settings of $hp_l_amp_zc_en$. To prevent zipper noise when gain ramping is selected, the gain is ramped through additional sub-range gain steps.

Alternatively, gain updates can be synchronized with signal zero-crossings by setting hp_l_amp_zc_en = 1. If no zero-crossing is detected within the timeout period, then the gain update is applied unconditionally. The timeout period is approximately 0.1 s, and is not user configurable.

The amplifier can be muted by setting hp_l_amp_mute_en = 1.

The amplifier can be put in its minimum gain configuration by setting $hp_l_amp_min_gain_en = 1$. If either zero-crossing or ramping are enabled when minimum gain is set, the ramping or the zero crossing will be performed while activating the minimum gain. The right-channel headphone amplifier (HP_R_CTRL) is controlled in the same manner.

Table 42: hp_l_amp_gain and hp_r_amp_gain Settings

9.4.3 Charge Pump Control

The charge pump is enabled by asserting cp_en in the CP_CTRL register. Once enabled, the charge pump can be controlled manually or automatically. When under manual control (cp_mchange = 00), the output voltage level is directly determined by cp_mod.

The amount of charge stored, and therefore the voltage generated, by the charge pump is controlled by the charge pump controller. As the power consumed by devices such as amplifiers is proportional to voltage, significant power savings are available by matching the charge pump's output with the system's power requirement.

Under automatic control, there are three modes of operation that are determined by the cp_mchange setting. All four modes (one manual and three automatic) are described in Table 43.

| Charge Pump Tracking Mode cp_mchange | Charge Pump Output Voltage | Details |
|--|---|--|
| 00 | Manual | The charge pump's output voltage is determined by the settings of cp_mod |
| 01 | Voltage level depends on the programmed gain setting | The charge pump controller monitors the PGA volume settings and generates the minimum voltage that is required to drive a full-scale signal at the current gain level |
| 10 | Voltage level depends on the DAC signal envelope | The charge pump controller monitors the DAC signal, and generates the voltage that is required to drive a full-scale output at the current DAC signal volume level |
| 11 | Voltage level depends on the signal magnitude and the programmed gain setting | The charge pump monitors both the programmed volume settings and the actual signal size, and generates the appropriate output voltage This is the most power-efficient mode of operation |

Table 43: Charge Pump Output Voltage Control

When cp_mchange is set to 10 (tracking DAC signal size, described in Table 43) or cp_mchange is set to 11 (tracking the output signal size), the charge pump switches its supply between the VDD rail and the VDD/2 rail depending on its power requirements. When low output voltages are needed, the charge pump saves power by using the lower-voltage VDD/2 rail.

The switching point between using the VDD rail and the VDD/2 rail is determined by the cp_thresh_vdd2 register setting. The switching points determined by cp_thresh_vdd2 vary between the two cp_mchange modes, and are summarized Table 44 and Table 45.

| cp_thresh_vdd2 Setting | Approximate Switching Point | Notes |
|------------------------|-----------------------------|--|
| 0x01 | -30 dBFS | Do not use. Very power-inefficient as nearly always VDD/1 |
| 0x03 | -24 dBFS | Not recommended. Very power-inefficient as nearly always VDD/1 |
| 0x07 | -18 dBFS | May be used but not power efficient |
| 0x0E | -12 dBFS | May be used |
| 0x10 | -10 dBFS | Recommended setting |
| 0x3F to 0x13 | | Reserved, do not use |

| cp_thresh_vdd2 Setting | Approximate Switching Point | Notes |
|------------------------|-----------------------------|---|
| 0x00 | Never | Not recommended. Always VDD/1 mode |
| 0x01 | Never | Not recommended. Always VDD/1 mode |
| 0x02 | -32 dBFS | Not recommended. Power-inefficient as nearly always VDD/1 |
| 0x03 | -24 dBFS | May be used |
| 0x04 | -20 dBFS | May be used |
| 0x05 | -17 dBFS | May be used |
| 0x06 | -15 dBFS | Recommended setting |
| 0x07 | -13 dBFS | May be used |
| 0x08 | -12 dBFS | May be used |
| 0x09 | -11 dBFS | May be used |
| 0x0A | -10 dBFS | May be used |
| 0x0B | -9 dBFS | Not recommended. VDD/2 begins to clip |
| 0x0C | Never | Not recommended. Always VDD/2 mode |
| 0x0D | Never | Not recommended. Always VDD/2 mode |
| 0x0E | Never | Not recommended. Always VDD/2 mode |
| 0x0F | Never | Not recommended. Always VDD/2 mode |

Table 45: cp_thresh_vdd2 Settings in Output Signal Tracking Mode (cp_mchange = 11)

9.4.3.1 Charge Pump Initial and Switching Current

At start-up, and when moving from VDD/2 to VDD/1 the charge pump output capacitors will be charged from the VDD supply rail. The initial current spike of 100 ns will be approximately 500 mA for a 1 μ F output capacitor. Ensure that the supply to VDD is capable of delivering this current. Placing a larger input capacitor on VDD will reduce the amount of instantaneous current pulled directly from the 1.8 V supply.Note that this does not apply to single supply mode operation.

Similarly, when moving from VDD/1 to VDD/2 the charge pump output capacitors will be discharged through the VDD supply rail. The initial current spike of 100 ns being sunk through VDD will be approximately 100 mA for a 1 μ F capacitor. Ensure that the supply to VDD is capable of sinking this current. Note that this does not apply to single supply mode operation.

9.4.4 Tracking the Demands on the Charge Pump Output

There are three points at which the demands on the charge pump can be tracked. These tracking points are determined by cp_mchange.

9.4.4.1 cp_mchange = 00 (Manual Mode)

If cp_mchange = 00, the voltage level is controlled by the cp_mod setting.

9.4.4.2 cp_mchange = 01 (Tracking the PGA Gain Setting)

If cp_mchange = 01, the PGA gain setting is tracked, and provides feedback to boost the clock frequency when necessary.

9.4.4.3 **cp_mchange = 10 (Tracking the DAC Signal Setting)**

If cp_mchange = 01, the size of the DAC signal is tracked, and provides the feedback to boost the clock frequency when necessary.

Datasheet

9.4.4.4 **cp_mchange = 11 (Tracking the Output Signal Magnitude)**

If cp_mchange = 01, the magnitude of the output signal is tracked, and provides the feedback to boost the clock frequency when necessary.

9.4.5 Specifying Clock Frequencies when Tracking the Charge Pump Output Demand

cp_fcontrol specifies the frequency of the charge pump clock. The frequency is fixed and is set manually if cp_mchange = 00 (see section 9.4.4.1). The available frequency settings are SYS_CLK/8 (the absolute maximum), and SYS_CLK/16, /32, /64 and /128. Where SYS_CLK is 12.288 MHz or 11.2896 MHz depending on sample rate.

If cp_mchange does not = 00, the charge pump load is monitored and the clock frequency adjusted accordingly to allow the charge pump to supply the required current. Clock frequency varies depending on the charge pump requirements, and the cp_fcontrol settings specify the minimum frequency at which the clock will run. The maximum frequency is always SYS_CLK/8.

In addition to the cp_fcontrol settings outlined above, and which specify the minimum clock frequency, there is an extra setting of cp_fcontrol = 101 which has no minimum frequency. At this setting, the clock frequency is under the complete control of the tracking and feedback mechanism. The frequency can vary from 0 Hz when there is no load on the charge pump and no component leakage, up to the maximum of SYS_CLK/8.

In general this setting can be left at its default value of 001.

9.4.6 Other Charge Pump Controls

When a higher charge pump output voltage is needed, the charge pump increases its output at the fastest rate possible given the controls and settings in that currently in place. Once the higher output voltage is no longer needed, the charge pump controller waits for a period determined by the cp_tau_delay setting before reducing the output voltage.

For best performance Dialog Semiconductor recommend setting cp_tau_delay to 16 ms or greater.

cp_small_switch_freq_en enables a low-load, low-power switching mode. If cp_small_switch_freq_en is enabled and cp_fcontrol is set to a value between 000 and 100, any feedback from the analog level detector results in a switch from low-power to full-power. Full-power is maintained for one cp_tau_delay period after the pulse, any subsequent pulses restart the cp_tau_delay period.

If $cp_fcontrol = 101$, the first feedback from the analog level detector primes the change to full-power mode. If another pulse occurs within 32 clock cycles of the first feedback from the analog level detector, full power is enabled for one cp_tau_delay period.

9.4.7 True-Ground Supply Mode

In true-ground supply mode, the charge pump must be enabled to generate the ground-centered supply rails for the amplifiers.

9.5 Phase Locked Loop

The DA7217 contains a Phase Locked Loop (PLL) that can be used to generate the required 11.2896 MHz or 12.288 MHz internal system clock when a frequency of between 2 and 54 MHz is applied to MCLK. This allows sharing of clocks between devices in an application, reducing total system cost. For example, the codec may operate from common 13 MHz or 19.2 MHz system clock frequency.

9.5.1 PLL Bypass Mode

If an MCLK signal (of [11.2896, 12.288, 22.5792, 24.576, 45.1584, or 49.152] MHz) that is synchronous with WCLK and BCLK is available, the PLL is not required and should be disabled to save power. PLL bypass mode is activated by setting pll_mode = 00.

In this mode the PLL is bypassed and an audio frequency clock is applied to the MCLK pin of the codec. The required clock frequency depends on the sample rate at which the audio DACs and ADCs are operating. These clock frequencies are summarized in Table 46 for the range of DAC and ADC sample rates that can be configured using the SR register.

Datasheet

| Table 40. Comm | In Data Control Do | | | |
|-----------------|--------------------|-------------------|----------------|-------------------|
| I able 46: Samp | le Rate Control Re | gister and Corres | ponding System | n Clock Frequency |

| Sample Rate, FS (kHz) | SR Register | System Clock Frequency (MHz) |
|-----------------------|-------------|------------------------------|
| 8 | 0001 | 12.288 |
| 11.025 | 0010 | 11.2896 |
| 12 | 0011 | 12.288 |
| 16 | 0101 | 12.288 |
| 22.05 | 0110 | 11.2896 |
| 24 | 0111 | 12.288 |
| 32 | 1001 | 12.288 |
| 44.1 | 1010 | 11.2896 |
| 48 | 1011 | 12.288 |
| 88.2 | 1110 | 11.2896 |
| 96 | 1111 | 12.288 |

If digital playback or record is required in bypass mode then the MCLK frequency should be set to (11.2896, 12.288, 22.5792, 24.576, 45.1584, or 49.152)MHz and pll_indiv should be programmed accordingly.

If no valid MCLK is detected, the output of the internal reference oscillator is used instead. However in this case only analog bypass paths may be used.

9.5.2 Normal PLL Mode (DAI Master)

The PLL is enabled by asserting pll_mode = 01. Once the PLL is enabled and has achieved phase lock, PLL bypass mode is disabled and the output of the PLL is used as the system clock.

The PLL input divider register (pll_indiv) is used to reduce the PLL reference frequency (2 MHz to 54 MHz) to the usable range of 2 MHz to 4.5 MHz as shown in Table 47, this reduces the PLL reference frequency according to the following equation:

FREF = FMCLK ÷ N

Table 47: PLL Input Divider

| MCLK Input Frequency (MHz) | Input Divider (÷N) | pll_indiv Register (0x27 [3:2]) |
|----------------------------|--------------------|---------------------------------|
| 2 to 4.5 | ÷1 | 000 |
| 4.5 to 9 | ÷2 | 001 |
| 9 to 18 | ÷4 | 010 |
| 18 to 36 | ÷8 | 011 |
| 36 to 54 | ÷16 | 100 |

The value of the PLL feedback divider is used to set the voltage controlled oscillator (VCO) frequency to eight times the required system clock frequency (see Table 46).

FVCO = FREF * PLL feedback divider

The value of the PLL feedback divider is an unsigned number in the range of 0 to 128. It consists of seven integer bits and thirteen fractional bits split across three registers:

- PLL_INTEGER holds the seven integer bits
- PLL_FRAC_BOT holds the top bits (MSB) of the fractional part of the divisor
- PLL_FRAC_BOT holds the bottom bits (LSB) of the fractional part of the divisor

Datasheet

9.5.3 Example Calculation of the Feedback Divider Setting:

Example: A codec operating with a sample rate (F_s) = 48 kHz and a reference input clock frequency of 12.288 MHz. The required output frequency is 98.304 MHz.

The reference clock input = 12.288 MHz, which falls in the range 10-20 MHz, so pll_indiv must be set to 0b010 dividing the reference input frequency by 4 (see Table 48).

The formula for calculating the feedback divider is:

Feedback divider (F) = VCO output frequency * input divider (pll_indiv) / reference input clock

Therefore Feedback divider (F) = (98.304 * 4) / 12.288 = 32

So:

- pll_fbdiv_integer (holding the seven integer bits) = 0x20
- pll_fbdiv_frac_top (holding the top bits (MSB) of the fractional part of the divisor) = 0x00
- pll_fbdiv_frac_bot (holding the bottom bits (LSB) of the fractional part of the divisor) = 0x00

Table 48 shows example register settings that will configure the PLL when using a 13 MHz, 15 MHz or 19.2 MHz clock. Note that any MCLK input frequency between 2 MHz and 54 MHz is supported. pll_indiv must be used to reduce the PLL reference frequency to the usable range of 2 MHz to 5 MHz as shown in Table 48.

| MCLK Input Frequency (MHz) | System Clock Frequency (MHz) | pll_mode Register | PLL_FRAC_TOP Register | PLL_FRAC_BOT Register | PLL_INTEGER Register |
|----------------------------------|------------------------------------|----------------------|--------------------------|--------------------------|-------------------------|
| 13 | 11.2896 | 0x01 | 0x19 | 0x45 | 0x1B |
| 13 | 12.288 | 0x01 | 0x07 | 0xEA | 0x1E |
| 15 | 11.2896 | 0x01 | 0x02 | 0xB4 | 0x18 |
| 15 | 12.288 | 0x01 | 0x06 | 0xDC | 0x1A |
| 19.2 | 11.2896 | 0x01 | 0x1A | 0x1C | 0x12 |
| 19.2 | 12.288 | 0x01 | 0x0F | 0x5C | 0x14 |

Table 48: Example PLL Configurations

9.5.4 Sample Rate Matching PLL Mode (DAI Slave)

Sample rate matching (SRM) mode enables the PLL output clock to be synchronized to the incoming WCLK signal on the DAI. The SRM PLL mode is enabled by setting pll_mode = 10.

When using the DAI in slave mode with the SRM enabled, removing and re-applying the DAI interface word clock WCLK may cause the PLL lock to be lost. To re-lock the PLL disable the SRM (pll_mode = 00), reset the PLL by re-writing to register PLL_INTEGER, and then re-enable the SRM (pll_mode = 10) after the DAI WCLK has been reapplied.

When switching sample rates between 44.1 kHz and 48 kHz (or between the multiples of these sample rates), SRM must be disabled then re enabled using register bit pll_mode.

squarer circuit.

Ultra-Low Power Stereo Codec

9.5.5 MCLK Input

MCLK is the master clock input which must be in the range of 2 MHz to 54 MHz.

MCLK can be applied as a full-amplitude square wave, or as a low-amplitude sine wave (if the MCLK squarer circuit has been enabled). The clock squarer circuit is enabled by writing pll_mclk_sqr_en = 1. The clock squarer circuit allows a sine wave or other low amplitude clock (down to 300 mVpp) to be applied to the chip. The MCLK input is AC coupled on chip when using the clock

9.5.5.1 MCLK Detection

A clock detection circuit will set bit [0] of pll_srm_status = 1 whenever the applied MCLK frequency is above the minimum detection frequency of approximately 1 MHz. Whenever this bit is High, the MCLK signal is selected as the clock input to the PLL.

9.5.6 Audio Reference Oscillator

For best audio performance, a system clock within the specified range is required. The DA7217 codec has an internal reference oscillator that provides the system clock when there is no valid MCLK signal.

The reference oscillator is automatically enabled whenever the codec is in ACTIVE mode and the MCLK frequency is below the absolute minimum frequency of 1 MHz. When the codec enters STANDBY mode, the oscillator is automatically disabled to save power.

9.5.6.1 Oscillator Calibration

The reference oscillator can be calibrated for use in low-power applications where no MCLK signal is supplied but where the system clock needs to be reasonably accurate. For example when using the level detection, the device can be set to automatically stream data to the host. If the oscillator has been calibrated then the DAI clocks will run within 5 % of the nominal frequency, allowing the data to be processed correctly by the host. To perform this calibration, the device requires a valid WCLK signal on the DAI (in either master or slave mode). The SRM block uses this as a reference against which to tune the oscillator. See section 9.5.6.2 for the calibration procedure.

The entire calibration block is enabled by setting pll_refosc_cal_en = 1. This enables both the initial calibration of the reference oscillator and the later use of the calibrated oscillator.

As long as the reference oscillator block has been enabled, the oscillator can be calibrated by writing 1 to pll_refosc_cal_start. Once the calibration has been completed, the pll_refosc_cal_start bit will return a 0 value. The 5-bit calibration value is stored in pll_refosc_cal_ctrl.

The reference oscillator runs automatically when in ACTIVE mode and when there is no valid MCLK signal. In STANDBY mode, the oscillator is automatically disabled to save power.

9.5.6.2 Procedure for Calibrating the Reference Oscillator

- 1. Apply a valid WCLK frequency
- 2. Set register PLL_REFOSC_CAL (address 0x98) = 0x80
- 3. The reference oscillator is now calibrated and will run whenever it is required

9.5.7 Internal System Clock

The internal system clock (SYSCLK) from which all other clocks are derived is normally one of two possible frequencies:

- 12.288 MHz for SR1 and SR2 from the 48 kHz family (8, 12, 16, 24, 32, 48, 96 kHz)
- 11.2896 MHz for SR1 and SR2 from the 44.1kHz family (11.025, 22.05, 44.1, 88.2 kHz)

The only exception to this is when the DAI is not used. In this case there is no requirement for a specific internal system clock frequency.

9.6 Reference Generation

9.6.1 Voltage References

The audio circuits use supply-derived references of 0.45*VDD (VMID) and 0.9*VDD (DACREF). There is also bandgap-derived fixed voltage reference of 1.2 V (VREF). All three voltage references require off-chip decoupling capacitors (see section 12 for further details).

Both VREF and VMID are automatically enabled whenever the device enters ACTIVE mode. They are automatically disabled when entering STANDBY mode.

The VMID reference comes from a high-resistance voltage divider, which combines with the decoupling capacitor to create a large RC (resistance-capacitance) time constant. This ensures a noise-free VMID reference, however the charge time is longer.

The bandgap reference VREF also takes time to charge its decoupling capacitor, but an internal timer ensures that no circuit that requires VREF is enabled until VREF has reached 1.2 V.

The DACREF voltage reference is produced from VMID by a times-two buffer so is capable of charging its decoupling capacitor quickly.

9.6.2 Bias Currents

DA7217 has a master bias current generation block that is enabled by default using the bias_en bit. Master bias current generation is set to on by default. Each sub-system has its own local current generation block, which is automatically enabled whenever any of its sub-blocks are enabled.

9.6.3 Voltage Levels

9.6.3.1 Digital Regulator

The digital engine is supplied from VDD. An internal LDO regulator can produce the internal rail VDDDIG. The regulator is controlled using the LDO_CTRL register and is enabled using the Ido_en bit. VDDDIG must not be used to drive external circuitry.

When the LDO is disabled, the regulator is in bypass mode and VDDDIG is shorted to VDD.

When the LDO is enabled, VDDDIG is regulated by the setting of Ido_en (see Table 49:).

Table 49: Audio Sub-System Digital LDO Level

| Ido_level_select Setting | LDO Level (V) |
|--------------------------|---------------|
| 00 | 1.05 |
| 01 | 1.10 |
| 10 | 1.20 |
| 11 | 1.40 |

9.6.3.2 Digital Input/Output Pins Voltage Level

The digital input/output (I/O) pins can be set to operate in either a high voltage (2.5 V to 3.6 V) or low voltage (1.5 V to 2.5 V) range using the io_voltage_level bit. This bit should be set to the relevant value based on the IO voltage level of the host.

9.7 I²C Control Interface

The DA7217 is completely software-controlled from the host via register writes. The DA7217 provides an I²C compliant serial control interface to access these registers. Data is shifted into or out of the DA7217 under the control of the host processor, which also provides the serial clock.

The I²C clock is supplied by the SCL line and the bi-directional I²C data is carried by the SDA line. The I²C interface is open-drain supporting multiple devices on a single line. The bus lines have to be pulled High by external pull-up resistors (1 k Ω to 20 k Ω range). The attached devices only drive the bus lines Low by connecting them to ground. This means that two devices cannot conflict if they drive the bus simultaneously.

Table 50: Device 7-Bit I²C Slave Addresses

| Pin AD | Device I ² C Address |
|--------|---------------------------------|
| High | 1B |
| Low | 1A |

In standard/fast mode the highest frequency of the bus is 1 MHz. The exact frequency can be determined by the application and does not have any relation to the DA7217 internal clock signals. DA7217 will follow the host clock speed within the described limitations and does not initiate any clock arbitration or slow down.

In high-speed mode the maximum frequency of the bus can be increased up to 3.4 MHz. This mode is supported if the SCL line is driven with a push-pull stage from the host and if the host enables an external 3 mA pull-up at the SDA pin to decrease the rise time of the data. In this mode the SDA line on DA7217 is able to sink up to 12 mA. In all other respects the high speed mode behaves as the standard/fast mode. Communication on the I²C bus always takes place between two devices, one acting as the master and the other as the slave. The DA7217 will only operate as a SLAVE in I²C communication.

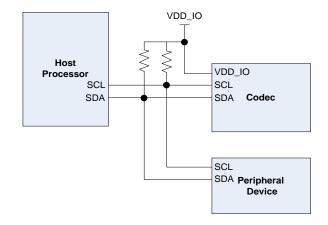

Figure 25: Schematic of the I²C Control Interface Bus

All data is transmitted across the I²C bus in groups of eight bits. To send a bit the SDA line is driven to the intended state while the SDA is Low (a LOW on SDA indicates a zero bit). Once the SDA has settled, the SCL line is brought HIGH and then LOW. This pulse on SCL clocks the SDA bit into the receiver's shift register.

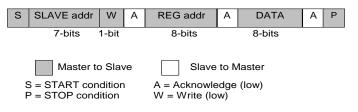

A two byte serial protocol is used containing one byte for address and one byte for data. Data and address transfer is transmitted MSB first for both read and write operations. All transmission begins with the START condition from the master while the bus is in the IDLE state (the bus is free). It is initiated by a HIGH to LOW transition on the SDA line while the SCL is in the HIGH state (a STOP condition is indicated by a LOW to HIGH transition on the SDA line while the SCL line is in the HIGH state).

Figure 26: Timing of I²C START and STOP Conditions

The I²C bus is monitored by DA7217 for a valid SLAVE address whenever the interface is enabled. It responds with an Acknowledge immediately when it receives its own slave address. The Acknowledge is achieved by pulling the SDA line LOW during the following clock cycle (white blocks marked with 'A' in Figure 27 to Figure 30).

The protocol for a register write from master to slave consists of a start condition, a slave address with read/write bit and the 8-bit register address followed by eight bits of data terminated by a STOP condition (the DA7217 responds to all bytes with an Acknowledge). This is illustrated in Figure 27.

When the host reads data from a register it first has to write access DA7217 with the target register address and then read access DA7217 with a repeated START, or alternatively a second START

| D- | 4 | | |
|-----|------|------|---|
| 112 | itas | s ne | ю |
| | | | |

01-Feb-2019

condition. After receiving the data the host sends a Not Acknowledge (NAK) and terminates the transmission with a STOP condition:

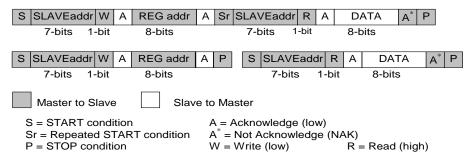

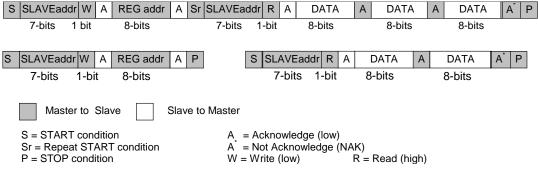

Figure 28: Examples of the I²C Byte Read (SDA line)

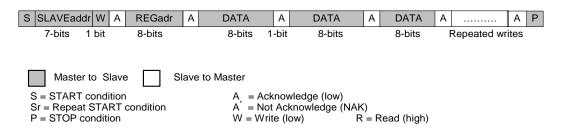

Consecutive (Page mode) Read-out mode (cif_i2c_write_mode = 0) is initiated from the master by sending an Acknowledge instead of Not Acknowledge (NAK) after receipt of the data word. The I²C control block then increments the address pointer to the next I²C address and sends the data to the master. This enables an unlimited read of data bytes until the master sends a NAK directly after the receipt of data, followed by a subsequent STOP condition. If a non-existent I²C address is read out, the DA7217 will return code zero.

The slave address after the Repeated START condition must be the same as the previous slave address.

Consecutive-write-mode (cif_i2c_write_mode = 0) is supported if the Master sends several data bytes following a slave register address. The I²C control block then increments the address pointer to the next I²C address, stores the received data and sends an Acknowledge until the master sends the STOP condition.

An alternative Repeated-write mode that uses non-consecutive slave register addresses is available using the cif_i2c_write_mode register. In this Repeat mode (cif_i2c_write_mode = 1), the slave can be configured to support a host's repeated write operations into several non-consecutive registers. Data is stored at the previously received register address. If a new START or STOP condition occurs within a message, the bus returns to IDLE mode. This is illustrated in Figure 31.

Figure 31: I²C Repeated Write (SDA Line)

In Page mode (cif_i2c_write_mode = 0), both Page mode reads and writes using auto incremented addresses, and Repeat mode reads and writes using non auto-incremented addresses, are supported. In Repeat mode (cif_i2c_write_mode = 1) however, only Repeat mode reads and writes are supported.

9.8 Digital Audio Interface

DA7217 provides one digital audio interface (DAI) to input DAC data or to output ADC data. It is enabled by asserting dai_en. The DAI provides flexible routing options allowing it to be connected to different signal paths as desired in each application.

The DAI consists of a four-wire serial interface, with bit clock (BCLK), word clock (WCLK), data-in (DATIN) and data-out (DATOUT) pins. Both Master and Slave clock modes are supported by the DA7217. Master mode is enabled by setting register dai_clk_en = 1. In Master mode, the bit clock and word clock signals are outputs from the codec. In Slave mode these are inputs to the codec.

In Master mode the frame length is configured using the dai_clk_enfield. In Slave mode this register is not used.

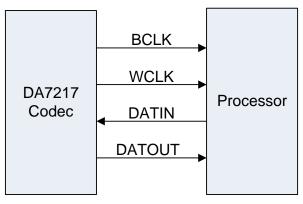

Figure 32: Master Mode (dai_clk_en = 1)

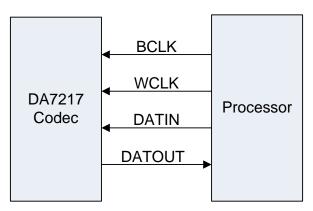

Figure 33: Slave Mode (dai_clk_en = 0)

| Datasheet | Revision 3.3 | 01-Fel |
|-----------|--------------|--------|
| | | |

b-2019

The internal serialized DAI data is 24 bits wide. Serial data that is not 24 bits wide is either shortened or zero-filled at input to, or at output from, the DAI's internal 24-bit data width. The serial data word length can be configured to be 16, 20, 24 or 32 bits wide using the dai_word_length register bits.

Four different data formats are supported by the DAI. The data format is determined by the setting of the dai_format register bits.

- I²S mode
- Left justified mode
- Right justified mode
- DSP mode

Time division multiplexing (TDM) is available in any of these modes to support the case where multiple devices are communicating simultaneously on the same bus. TDM is enabled by asserting the dai_tdm_mode_en bit.

9.8.1 DAI Channels

The DAI supports one to four channels, even in non-TDM modes. The number of channels required is specified by setting dai_ch_num bit which controls the position of the channels as shown in Figure 34.

| BCLK | | | |
|------------------|-----------------------|-----------------------|--|
| WCLK_ | | | |
| DATIN/ DATOUT | Channel 1L | | Channel 1L DAI_CH_NUM = 1 |
| DATIN/ DATOUT | Channel 1L | Channel 1R | Channel 1L DAI_CH_NUM = 2 |
| DATIN/ DATOUT | Channel 1L Channel 2L | Channel 1R | Channel 1L Channel 2L — DAI_CH_NUM = 3 |
| DATIN/ DATOUT | Channel 1L Channel 2L | Channel 1R Channel 2R | Channel 1L Channel 2L — DAI_CH_NUM = 4 |

Figure 34: Effect of dai_ch_num Bit on DAI Channel Positions (Non-TDM Mode)

In TDM mode, each of the four channels can be individually enabled using the dai_tdm_mode_en bit as shown in Figure 35.

| BCLK | | | | | 1 | | | | | | | | | | | | L | | | |

Datasheet

9.8.2 DAI WCLK Tristate Mode

For systems that use the BCLK output of DA7217 as a reference clock, it is possible to tristate the WCLK signal even when BCLK is acting as an output. This is done by enabling DAI Master mode (dai_clk_en = 1) and WCLK tristate (dai_wclk_tri_state = 1).

9.9 Interrupt Control

The nIRQ output can be used to signal to the host that an event has been detected by the codec. The event that triggered the interrupt can be revealed by reading the EVENT register. Events can be excluded from generating interrupts using the EVENT_MASK register.

9.9.1 Level Detect Events

The input level-detect event status can be seen in lvl_det_event , and cleared by writing $lvl_det_event = 1$. Level-detect events can be excluded by setting $lvl_det_event_msk = 1$.

9.10 System Settings

9.10.1 Sample Rate

The inputs (ADC) and the outputs (DAC) can be set to operate at independent sample rates using sr_adc and sr_dac. The only condition is that either the ADC sample rate or the DAC sample rate must be an integer or multiple of the other. The DAI will operate at whichever of the ADC or DAC sample rates is faster, and samples for the slower of the two will be repeated on the DAI.

9.10.2 Gain Ramp Rate

The rate at which all gains are ramped is controlled by the one register field gain_ramp_rate. The four possible settings and ramping rates controllable by the GAIN_RAMP_CTRL register are:

Table 51: Ramp Rate Settings Applicable to All Ramp-Enabled Gains

| gain_ramp_rate Setting | Ramping Rate (Note 1) | | |
|------------------------|---------------------------------|--|--|
| 00 | 0 = nominal rate * 8 (fastest) | | |
| 01 | 1 = nominal rate | | |
| 10 | 2 = nominal rate / 8 | | |
| 11 | 3 = nominal rate / 16 (slowest) | | |

Note 1 Nominal rate = 0.88 ms/dB

9.10.3 Program Counter Control

The program counter runs from the internal system clock and needs to be synchronized with the DAI so that data is sampled and delivered at the correct time with respect to the DAI clocks. Synchronization behavior is controlled using the PC_COUNT register.

The program counter can be set to automatically resync to the DAI using pc_resync_auto. It can be set to freerun without the need for DAI clocks using pc_freerun.

9.10.4 Soft Reset

The device can be reset (all register values reset to their default values) by writing cif_reg_soft_reset = 0x80.

This is an abrupt reset. To avoid pops and clicks, all audio paths must be shut down prior to issuing a soft reset.

Table 108: DGS_RISE_FALL (Page 0: 0x00000056)

| Bit | Mode | Symbol | Description | Reset |
|-----|------|----------------|--|-------|
| 6:4 | R/W | dgs_fall_coeff | Control volume estimation Leaky-integrator fall rate. This register sets the fraction of the input signal that is used to calculate the rolling average for all input channels in the DAC Gain Swap (DGS) when the input signal is smaller than signal average. 000 = 1/4 001 = 1/16 010 = 1/64 011 = 1/256 100 = 1/1024 101 = 1/4096 110 = 1/16384 111 = 1/65536 | 0x5 |
| 2:0 | R/W | dgs_rise_coeff | Control volume estimation Leaky-integrator rise rate. This register sets the fraction of the input signal that is used to calculate the rolling average for all input channels in the DAC Gain Swap (DGS) when the current input is larger than current average. 001 = 1/1 (average == signal) 010 = 1/16 011 = 1/64 100 = 1/256 101 = 1/1024 110 = 1/4096 111 = 1/16384 | 0x0 |

Table 109: DGS_SYNC_DELAY (Page 0: 0x00000057)

| Bit | Mode | Symbol | Description | Reset |
|-----|------|----------------|---|-------|
| 7:0 | R/W | dgs_sync_delay | User-defined sync-delay measured in Fs*8 clk periods. This delay is applied between Digital and Analogue gain updates to match the datapath delay through the DAC from the point of Digital gain application to the Analogue gain application. The delay is measured from the start of the frame in which the Digital gain is applied. | 0xA3 |

Table 110: DGS_SYNC_DELAY2 (Page 0: 0x00000058)

| Bit | Mode | Symbol | Description | Reset |
|-----|------|-----------------|---|-------|
| 7:0 | R/W | dgs_sync_delay2 | User-defined sync-delay measured in Fs*8 clk periods (exactly as dgs_sync_delay), but this delay setting is applied when the data-delay has been reduced due to operating at faster sample rates of: 88/96k (non-low-power) 44/48k (low-power) This delay is applied between Digital and Analogue gain updates to match the datapath delay through the DAC from the point of Digital gain application to the Analogue gain application. The delay is measured from the start of the frame in which the Digital gain is applied. The switch to this delay value is performed automatically. | 0x31 |

Table 111: DGS_SYNC_DELAY3 (Page 0: 0x00000059)

| Bit | Mode | Symbol | Description | Reset |
|-----|------|-----------------|--|-------|
| 6:0 | R/W | dgs_sync_delay3 | User-defined sync-delay measured in Fs*16 clk periods (similar to dgs_sync_delay), but this delay setting is applied when the data-delay has been reduced due to operating in voice filter modes where the DGS operates on Fs*2 data. This delay is applied between Digital and Analogue gain updates to match the datapath delay through the DAC from the point of Digital gain application to the Analogue gain application. The delay is measured from the start of the frame in which the Digital gain is applied. | 0x11 |

| Bit | Mode | Symbol | Description | Reset |
|-----|------|------------------|--|-------|
| 7:4 | R/W | dgs_signal_lvl | Trigger Level for application of gain. Once input drops below this level, the DGS will start applying the calculated gain-swaps. 0000 = 0 dB (swaps started immediately) 0001 = -6 dB 0010 = -12 dB continuing in -6 dB steps to 1110 = -86 dB 1111 = -90 dB | 0x0 |
| 2:0 | R/W | dgs_anticlip_lvl | Trigger Level for the Anti-clip feature. Once input rises above this level, the DAC Gain Swap (DGS) will turn off immediately, removing all steps to prevent clipping. This parameter should not need to be changed from the default. 000 = 0 dB 001 = -6 dB 010 = -12 dB continuing in -6 dB steps to 110 = -36 dB 111 = -42 dB | 0x1 |

Table 112: DGS_LEVELS (Page 0: 0x0000005A)

Table 113: DGS_GAIN_CTRL (Page 0: 0x0000005B)

| Bit | Mode | Symbol | Description | Reset |
|-----|------|-------------|---|-------|
| 6 | R/W | dgs_subr_en | DGS Gain-subrange Mode. If DAC Gain Swapping (DGS) ramping is enabled, DGS normally ramps the gain in 1.5 dB steps. Setting this register field reduces the ramp step-size so there are no audible artifacts. | 0x1 |
| | | | 0 = Gain-ramping is performed in 1.5 dB steps 1 = Gain-ramping is performed in more gradual steps without audible artifacts Note that this register only has an effect if dgs_ramp_en = 1 | |
| 5 | R/W | dgs_ramp_en | DGS Gain-Ramping control 0 = Ramping is disabled. The gain steps are applied immediately 1 = Ramping is enabled. The gain steps are ramped in 1.5 dB increments (or in 0.5 dB steps if dgs_sub_en is set) | 0x1 |
| 4:0 | R/W | dgs_steps | Maximum number of DAC Gain Swap (DGS) steps of 1.5 dB to apply. If sub-ranging is active, this setting still applies to the number of 1.5 dB steps to apply, and not to the number of sub-ranging steps. | 0x14 |

13 Ordering Information

The ordering number consists of the part number followed by a suffix indicating the packing method. For details and availability, please consult Dialog Semiconductor's customer portal or your local sales representative.

Table 262: Ordering Information (Samples)

| Part Number | Package | Shipment Form | Pack Quantity |
|--------------|---------------------------------|--|---------------|
| DA7217-00U32 | 32-bump WL-CSP Pb free/green | Tape and Reel (mini reel) (engineering samples only - not for mass production) | 100/1000 |
| DA7217-00U36 | 32-bump WL-CSP Pb free/green | Tray/Waffle Pack (engineering samples only - not for mass production) | 77 |

Table 263: Ordering Information (Production)

| Part Number | Package | Shipment Form | Pack Quantity |
|--------------|---------------------------------|---------------------------------|---------------|
| DA7217-00U32 | 32-bump WL-CSP Pb free/green | Tape and Reel (13 inch reel) | 7500 |

Appendix A Applications Information

A.1 Codec Initialization

Depending on the specific application, some general settings need to be set. Examples of these settings include the sample rate, the PLL, and the DAI. Then the amplifiers, the mixers and channels of the ADC/DAC have to be configured and enabled via their respective control registers.

An example sequence is shown below:

- 1. Configure clock mode as required for operation, (for example PLL or PLL bypass).
- 2. Configure the DAI.
- 3. Configure the charge pump if the headphone path is in use.
- 4. Set input and output mixer paths and gains.
- 5. Enable input and output paths using the Level 2 System Controller (SLC2).

A.2 Automatic Level Control Calibration

When using the automatic level control (ALC or AGS) in sync-mode the DC offset between the digital and analog PGAs must be cancelled. This is performed automatically if the following procedure is performed:

- 1. Enable microphone amplifiers unmuted.
- 2. Mute microphones.
- 3. Enable input mixer and ADC unmuted.
- 4. Enable AIF interface.
- 5. Set calib_auto_en in CALIB_CTRL to '1' (CALIB_CTRL = 0x44). This bit will auto-clear when calibration is complete.
- 6. When calibration is complete, enable the ALC with alc_sync_mode (ALC_CTRL1 = 0x30) and calib_offset_en (CALIB_CTRL = 0x44).
- 7. Unmute microphones.

Appendix B Components

The following recommended components are examples selected from requirements of a typical application. The electrical characteristics (that is, the supported voltage/current ranges) have to be cross-checked and component types may need to be adapted for the individual needs of the target circuitry.

B.1 Audio Inputs

Table 264: Audio Inputs

| Pin Name | Ball No. | Power Domain | Description | Туре |
|-----------------|--|--------------|---|-----------------------------------|
| MIC1_P/DMIC1CLK | _P/DMIC1CLK A15 VDD / Single-ended mic | | Differential mic. input 1 (positive) / Single-ended mic. input 1 (left) Or Digital microphone 1 clock | Analog input or digital output |
| MIC1_N/DMIC1N | B14 | VDD | Differential mic. input 1 (negative) / Single-ended mic. input 2 (left) Or Digital microphone 1 data | Analog input or digital input |
| MIC2_P/DMIC2CLK | IIC2_P/DMIC2CLK D16 VDD | | Differential mic. input 2 (positive) / Single-ended mic. input 1 (right) Or Digital microphone 2 clock | Analog input or digital output |
| MIC2_N/DMIC2IN | C15 | VDD | Differential mic. input 2 (negative) / Single-ended mic. input 2 (right) Or Digital microphone 2 data | Analog input or digital input |

The DA7217 microphone inputs can be configured to accommodate single-ended or differential analog microphones, line inputs or digital microphones.

When using the inputs in an analog configuration, a DC blocking capacitor is required for each used input. The choice of capacitor is determined by the filter that is formed between that capacitor and the input impedance of the input pin which can be found in Table 6, the Microphone amplifier electrical characteristics section of the datasheet.

$$C = \frac{1}{2\pi . R. F_c}$$

Where Fc is the 3 dB cut off frequency of the low pass filter (typically 20 Hz for audio applications). A 1 μ F capacitor is suitable for most applications.

Due to their high stability tantalum capacitors are particularly suitable for this application. Ceramic equivalents with an X5R dielectric are recommended as a cost effective alternative. Care should be taken to ensure that the desired capacitance is maintained over operating temperature and voltage.

Z5U dielectric ceramics should be avoided due to their susceptibility to microphonic effects.

Unused inputs can be left floating or connected via a capacitor to ground.

When the inputs are configured for digital microphones, these pins can be routed directly to a digital microphones clock and data lines. In stereo mode they can be connected to two digital microphones for each data/clock pair to allow up to four digital microphones to be connected to the device. Each data lane is configured to receive data on the rising clock edge for one channel, and on the falling edge for the other channel. The clock output operates at 1.536 MHz or 1.4112 MHz, or at 3.072 MHz or 2.8224 MHz. The appropriate layout considerations for clock signals should be followed.

B.2 Microphone Bias

Table 265: Microphone Bias

| Pin Name | Bump/Pin | Power Domain | Description | Туре | |
|----------|----------|--------------|--------------------------|---------------|--|
| MICBIAS1 | B12 | VDD_MIC | Microphone bias output 1 | Analog output | |
| MICBIAS2 | B16 | VDD_MIC | Microphone bias output 2 | Analog output | |

A 1 μ F capacitor to GND should be used to decouple the MICBIAS output.

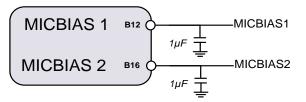

Figure 38: MICBIAS Decoupling

B.3 Audio Outputs

Table 266: DA7217 Headphone Outputs

| Pin Name | Bump/Pin | Power Domain | Description | Туре |
|----------|----------|--------------|---|---------------|
| HPL_P | A5 | VDD | Differential headphone output (left) positive | Analog output |
| HPL_N | B6 | VDD | Differential headphone output (left) negative | Analog output |
| HPR_P | B4 | VDD | Differential headphone output (right) positive | Analog output |
| HPR_N | A3 | VDD | Differential headphone output (right) negative | Analog output |

DA7217 contains a stereo differential headphone amplifier. For optimum noise immunity each headphone channels P and N connections should be routed together and connected differentially across the headphone load. In this configuration the differential routing cancels common mode noise on the headphone from the PCB.

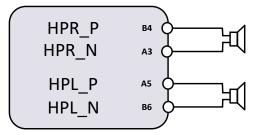

Figure 39: DA7217 Recommended Headphone Layout

B.4 Headphone Charge Pump

Table 267: Headphone Charge Pump

| Pin Name | Bump/Pin | Power Domain | Description | Туре |
|----------|----------|--------------|---------------------------------------|-------------|
| HPCSP | A1 | VDD | Charge pump reservoir capacitor (pos) | Charge pump |
| HPCSN | D2 | VDD | Charge pump reservoir capacitor (neg) | Charge pump |
| HPCFP | C1 | VDD | Charge pump flying capacitor (pos) | Charge pump |
| HPCFN | C3 | VDD | Charge pump flying capacitor (neg) | Charge pump |

A 1 μ F reservoir capacitor is required between the HPCSP and GND and between HPCSN and GND when the charge pump is used. For best performance the capacitors should be fitted as near to the device as possible.

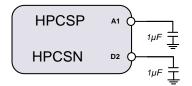

Figure 40: Charge Pump Decoupling

A 1 μ F flying capacitor is required between HPCFP and HPCFN. For best performance the capacitor should be fitted as near to the device as possible.

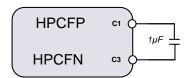

Figure 41: Charge Pump Flying Capacitor

To ensure stable charge pump operation the effective series resistance of the flying capacitor should be kept to a minimum. This can be achieved by selecting an appropriate capacitor dielectric (X5R, X7R) and ensuring that the capacitor is placed as near to the device as possible. Ideally the connection between the pins and the capacitor should not run through any vias. Connect on top layer of PCB only.

B.4.1 Single Supply Mode

When using the device in Single supply mode the charge pump is not used. HPCSP becomes the positive supply for the headphone amplifier (usually tied to VDD) and the HPCSN ball becomes the negative supply for the headphone amplifier (tied to GND). A 1 µF reservoir capacitor is required between the HPCSP and GND.

In Single supply mode the HPCFP and HPCFN pins should be left floating.

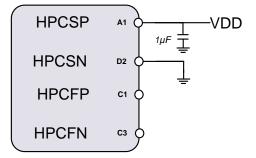

Figure 42: Single Supply Mode Operation

| Datasheet | Revision 3.3 | 01-Feb-2019 |
|-----------|--------------|-------------|
| | | |

B.5 Digital Interfaces

Table 268: Digital Interfaces – I²C

| Pin Name | Bump/Pin | Power Domain | Description | Туре |
|----------|----------|--------------|-------------------------------------|---------------------------|
| SDA | D12 | VDD_IO | I ² C bidirectional data | Digital input / output |
| SCL | C11 | VDD_IO | I ² C clock input | Digital input |

The I²C data and clock lines are powered from VDD_IO. Both I²C line require a pull up to VDD_IO. The value of this pull up is dependent on I²C bus speed, bus length and supply voltage. A 2.2 k Ω resistor is satisfactory in most applications.

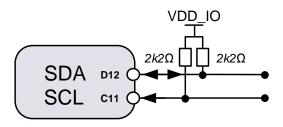

Figure 43: I²C Pull Ups

Table 269: Digital Interfaces - I²S

| Pin Name | Bump/Pin | Power Domain | Description | Туре |
|----------|----------|--------------|-----------------------------|---------------------------|
| DATIN | C7 | VDD_IO | DAI data input | Digital input |
| DATOUT | C9 | VDD_IO | DAI data output | Digital output |
| BCLK | D6 | VDD_IO | DAI bit clock | Digital input / output |
| WCLK | D8 | VDD_IO | DAI word clock (L/R select) | Digital input / output |
| MCLK | D10 | VDD_IO | Master clock | Digital input |

The DAI interface pins should be treated as clock signals and the appropriate layout rules for routing clocks should be adhered to.

Datasheet

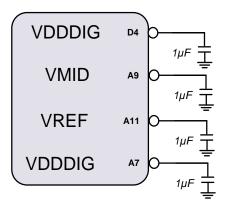

B.6 References

Table 270: References

| Pin Name | Bump/Pin | Power Domain Description | | Туре |
|----------|----------|--------------------------|------------------------------------|-----------|
| VDDDIG | D4 | VDD | Digital supply reference capacitor | Reference |
| VMID | A9 | VDD | Audio mid-rail reference capacitor | Reference |
| VREF | A11 | VDD | Bandgap reference capacitor | Reference |
| DACREF | A7 | VDD | Audio DAC reference capacitor | Reference |

A 1 μ F capacitor should be connected between each of the references and GND. For best performance the capacitors should be fitted as near to the device as possible.

B.7 Supplies

Table 271: Power Supplies

| Pin Name | Bump/Pin | Power Domain | Description | Туре |
|----------|----------|---------------------------|---|--------------|
| VDD | B8 | Min: 1.7 V Max: 2.65 V | Supply for analog circuits / Supply for headphone charge pump | Power supply |
| VDD_IO | C5 | Min: 1.5 V Max: 3.6 V | Supply for digital interfaces | Power supply |
| VDD_MIC | A13 | Min: 1.8 V Max: 3.6 V | Supply for microphone bias circuits | Power supply |

Decoupling capacitors are recommended between all supplies and GND. These capacitors should be located as near to the device as possible.

VDD B8
VDD_IO C5
VDD_MIC A13

$$1\mu F \pm 1.7V - 2.65 V$$

 $1\mu F \pm 1.5V - 3.6V$
 $1\mu F \pm 1.8V - 3.6V$

Figure 45: Power Supply Decoupling

B.8 Ground

Table 272: Ground

| Pin Name | Bump/Pin | Power Domain | Description | Туре |
|----------|----------|--------------|----------------------------|--------------|
| GND | B10 | | Analog ground | Power ground |
| GND_CP | B2 | | Charge pump/digital ground | Power ground |

GND and GND_CP should be connected directly to the system ground.

B.9 Capacitor Selection

Ceramic capacitors are manufactured with a variety of dielectrics, each with a different behavior over temperature and applied voltage. Capacitors must have a dielectric adequate to ensure the minimum capacitance over the necessary temperature range, dc bias conditions and low Equivalent Series Resistance (ESR). X5R or X7R dielectrics with a voltage rating of 6.3 V or 10 V are recommended for best performance. Y5V and Z5U dielectrics are not recommended for use because of their poor temperature and dc bias characteristics.

The worst-case capacitance accounting for capacitor variation over temperature, component tolerance, and voltage is calculated using the following equation:

$$C_{EFF} = C_{OUT} x (1 - TEMPCO) x (1 - TOL)$$

Where: CEFF is the effective capacitance at the operating voltage. TEMPCO is the worst-case capacitor temperature coefficient. TOL is the worst-case component tolerance. These figures can be found in the manufacturer's datasheet.

In the example below, the worst-case temperature coefficient (TEMPCO) over -55 °C to +85 °C is assumed to be 15 %. The tolerance of the capacitor (TOL) is assumed to be 10 %, and COUT is 0.65 μ F at 1.8 V.

Substituting these values in the equation yields

$$C_{EFF} = 0.65 \mu F x (1 - 0.15) x (1 - 0.1) = 0.497 \mu F$$

| Application | Value | Size | Temp. Char. | Tolerance | Rated Voltage | Туре |
|--|----------|------|-----------------|-----------|------------------|-----------------------|
| VDD,VDD_IO, VDD_MIC, VDDDIG, DACREF, VMID,VREF, HPCFP/HPCFN, HPCSP, HPCSN, MICBIAS1, MICBIAS2 | 12x 1 µF | 0201 | X5R +/- 15 % | +/-10 % | 6.3 V | Murata GRM033R60J105M |

Table 273: Recommended Capacitor Types

Appendix C PCB Layout Guidelines

DA7217 uses Dialog Semiconductor's 'Route Easy™' technology allowing the device to be routed using conventional, low cost, PCB technology. All device balls are routable on the top level and conventional plated through hole vias can be used throughout.

This design is fully realizable using a 2-layer PCB however for optimum performance it is recommended that a 4-layer PCB is used with layers 2 and 3 as solid ground planes.

Decoupling and reference capacitors should be located as close to the device as possible and appropriately sized tracks should be used for all power connections.

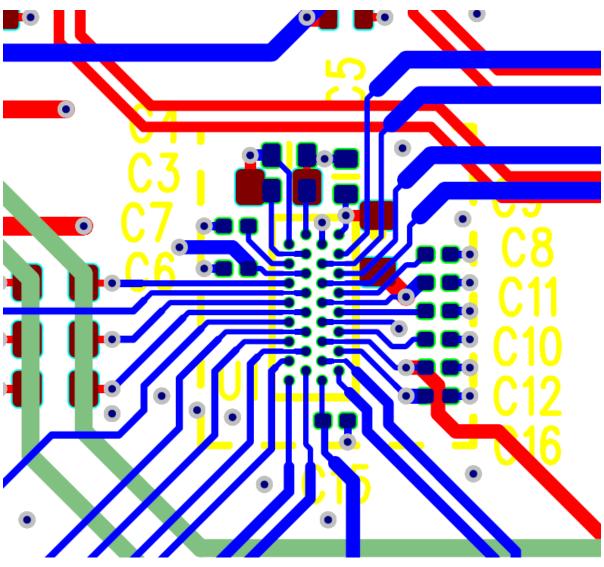

Figure 46: DA7217 Example Layout

C.1 Layout and Schematic Support

Copies of the evaluation board schematics and layout are available on request to aid in PCB development. Dialog Semiconductor also offer a schematic and layout review service for all designs utilizing Dialog's devices. Please contact your local Dialog Semiconductor office.

| D: | ats | ish | 00 | 4 |
|----|-----|------|----|---|
| | ate | 1311 | | |

C.2 General Recommendations

- Appropriate trace width and number of vias should be used for all power supply paths
- A common ground plane should be used, which allows proper electrical and thermal performance
- Noise-sensitive analog signals such as feedback lines or clock connections should be kept away from traces carrying pulsed analog or digital signals. This can be achieved by separation (distance) or by shielding with quiet signals or ground traces
- Decoupling capacitors should be X5R ceramics and should be placed as near to the device as possible
- Charge pump capacitors should be X5R ceramics and should be placed as near to the device as possible

Revision 3.3

01-Feb-2019

Общество с ограниченной ответственностью «МосЧип» ИНН 7719860671 / КПП 771901001 Адрес: 105318, г.Москва, ул.Щербаковская д.З, офис 1107

Данный компонент на территории Российской Федерации

Вы можете приобрести в компании MosChip.

Для оперативного оформления запроса Вам необходимо перейти по данной ссылке:

http://moschip.ru/get-element

Вы можете разместить у нас заказ для любого Вашего проекта, будь то серийное производство или разработка единичного прибора.

В нашем ассортименте представлены ведущие мировые производители активных и пассивных электронных компонентов.

Нашей специализацией является поставка электронной компонентной базы двойного назначения, продукции таких производителей как XILINX, Intel (ex.ALTERA), Vicor, Microchip, Texas Instruments, Analog Devices, Mini-Circuits, Amphenol, Glenair.

Сотрудничество с глобальными дистрибьюторами электронных компонентов, предоставляет возможность заказывать и получать с международных складов практически любой перечень компонентов в оптимальные для Вас сроки.

На всех этапах разработки и производства наши партнеры могут получить квалифицированную поддержку опытных инженеров.

Система менеджмента качества компании отвечает требованиям в соответствии с ГОСТ Р ИСО 9001, ГОСТ РВ 0015-002 и ЭС РД 009
