

5 V, 16 Kbit (2 Kb x 8) ZEROPOWER[®] SRAM**Features**

- Integrated, ultra low power SRAM and power-fail control circuit
- Unlimited WRITE cycles
- READ cycle time equals WRITE cycle time
- Automatic power-fail chip deselect and WRITE protection
- WRITE protect voltages (V_{PFD} = power-fail deselect voltage):
 - M48Z02: $V_{\text{CC}} = 4.75$ to 5.5 V;
 $4.5 \text{ V} \leq V_{\text{PFD}} \leq 4.75 \text{ V}$
 - M48Z12: $V_{\text{CC}} = 4.5$ to 5.5 V;
 $4.2 \text{ V} \leq V_{\text{PFD}} \leq 4.5 \text{ V}$
- Self-contained battery in the CAPHAT[™] DIP package
- Pin and function compatible with JEDEC standard 2 K x 8 SRAMs
- RoHS compliant
 - Lead-free second level interconnect

1 Description

The M48Z02/12 ZEROPOWER[®] RAM is a 2 K x 8 non-volatile static RAM which is pin and function compatible with the DS1220.

A special 24-pin, 600 mil DIP CAPHAT[™] package houses the M48Z02/12 silicon with a long-life lithium button cell to form a highly integrated battery-backed memory solution.

The M48Z02/12 button cell has sufficient capacity and storage life to maintain data functionality for an accumulated time period of at least 10 years in the absence of power over commercial operating temperature range.

The M48Z02/12 is a non-volatile pin and function equivalent to any JEDEC standard 2 K x 8 SRAM. It also easily fits into many ROM, EPROM, and EEPROM sockets, providing the non-volatility of PROMs without any requirement for special WRITE timing or limitations on the number of WRITES that can be performed.

2 Operation modes

The M48Z02/12 also has its own power-fail detect circuit. The control circuitry constantly monitors the single 5 V supply for an out of tolerance condition. When V_{CC} is out of tolerance, the circuit write protects the SRAM, providing a high degree of data security in the midst of unpredictable system operation brought on by low V_{CC} . As V_{CC} falls below approximately 3 V, the control circuitry connects the battery which maintains data operation until valid power returns.

1. See [Table 10 on page 16](#) for details.

Note: $X = V_{IH}$ or V_{IL} ; V_{SO} = battery backup switchover voltage.

2.1 READ mode

The M48Z02/12 is in the READ mode whenever \bar{W} (WRITE enable) is high and \bar{E} (chip enable) is low. The device architecture allows ripple-through access of data from eight of 16,384 locations in the static storage array. Thus, the unique address specified by the 11 Address Inputs defines which one of the 2,048 bytes of data is to be accessed. Valid data will be available at the data I/O pins within address access time (t_{AVQV}) after the last address input signal is stable, providing that the \bar{E} and \bar{G} access times are also satisfied. If the \bar{E} and \bar{G} access times are not met, valid data will be available after the latter of the chip enable access time (t_{ELQV}) or output enable access time (t_{GLQV}).

The state of the eight three-state data I/O signals is controlled by \bar{E} and \bar{G} . If the outputs are activated before t_{AVQV} , the data lines will be driven to an indeterminate state until t_{AVQV} . If the address inputs are changed while \bar{E} and \bar{G} remain active, output data will remain valid for output data hold time (t_{AXQX}) but will go indeterminate until the next address access.

Note: WRITE enable (\bar{W}) = high.

1. Valid for ambient operating temperature: $T_A = 0$ to 70 °C or -40 to 85 °C; $V_{CC} = 4.75$ to 5.5 V or 4.5 to 5.5 V (except where noted).

2.2 WRITE mode

The M48Z02/12 is in the WRITE mode whenever \bar{W} and \bar{E} are active. The start of a WRITE is referenced from the latter occurring falling edge of \bar{W} or \bar{E} . A WRITE is terminated by the earlier rising edge of \bar{W} or \bar{E} . The addresses must be held valid throughout the cycle. \bar{E} or \bar{W} must return high for a minimum of t_{EHAX} from chip enable or t_{WHAX} from WRITE enable prior to the initiation of another READ or WRITE cycle. Data-in must be valid t_{DVWH} prior to the end of WRITE and remain valid for t_{WHDX} afterward. \bar{G} should be kept high during WRITE cycles to avoid bus contention; although, if the output bus has been activated by a low on \bar{E} and \bar{G} , a low on \bar{W} will disable the outputs t_{WLQZ} after \bar{W} falls.

1. Valid for ambient operating temperature: T_A = 0 to 70 °C or -40 to 85 °C; V_{CC} = 4.75 to 5.5 V or 4.5 to 5.5 V (except where noted).

2.3 Data retention mode

With valid V_{CC} applied, the M48Z02/12 operates as a conventional BYTEWIDE™ static RAM. Should the supply voltage decay, the RAM will automatically power-fail deselect, write protecting itself when V_{CC} falls within the V_{PFD} (max), V_{PFD} (min) window. All outputs become high impedance, and all inputs are treated as “don't care.”

Note: A power failure during a WRITE cycle may corrupt data at the currently addressed location, but does not jeopardize the rest of the RAM's content. At voltages below V_{PFD} (min), the user can be assured the memory will be in a write protected state, provided the V_{CC} fall time is not less than t_F. The M48Z02/12 may respond to transient noise spikes on V_{CC} that reach into the deselect window during the time the device is sampling V_{CC}. Therefore, decoupling of the power supply lines is recommended.

The power switching circuit connects external V_{CC} to the RAM and disconnects the battery when V_{CC} rises above V_{SO}. As V_{CC} rises, the battery voltage is checked. If the voltage is too low, an internal Battery Not OK (BOK) flag will be set. The BOK flag can be checked after power up. If the BOK flag is set, the first WRITE attempted will be blocked. The flag is automatically cleared after the first WRITE, and normal RAM operation resumes. [Figure 7 on page 11](#) illustrates how a BOK check routine could be structured.

For more information on a battery storage life refer to the application note AN1012.

Figure 7. Checking the $\overline{\text{BOK}}$ flag status

2.4 V_{CC} noise and negative going transients

I_{CC} transients, including those produced by output switching, can produce voltage fluctuations, resulting in spikes on the V_{CC} bus. These transients can be reduced if capacitors are used to store energy which stabilizes the V_{CC} bus. The energy stored in the bypass capacitors will be released as low going spikes are generated or energy will be absorbed when overshoots occur. A ceramic bypass capacitor value of 0.1 μF (as shown in [Figure 8](#)) is recommended in order to provide the needed filtering.

In addition to transients that are caused by normal SRAM operation, power cycling can generate negative voltage spikes on V_{CC} that drive it to values below V_{SS} by as much as one volt. These negative spikes can cause data corruption in the SRAM while in battery backup mode. To protect from these voltage spikes, STMicroelectronics recommends connecting a Schottky diode from V_{CC} to V_{SS} (cathode connected to V_{CC}, anode to V_{SS}). Schottky diode 1N5817 is recommended for through hole and MBR5120T3 is recommended for surface mount.

Figure 8. Supply voltage protection

3 Maximum ratings

Stressing the device above the rating listed in the absolute maximum ratings table may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 5. Absolute maximum ratings

| Symbol | Parameter | | Value | Unit |
|-----------------|---|---------|-----------|------|
| T_A | Ambient operating temperature | Grade 1 | 0 to 70 | °C |
| T_{STG} | Storage temperature (V_{CC} off, oscillator off) | | -40 to 85 | °C |
| $T_{SLD}^{(1)}$ | Lead solder temperature for 10 seconds | | 260 | °C |
| V_{IO} | Input or output voltages | | -0.3 to 7 | V |
| V_{CC} | Supply voltage | | -0.3 to 7 | V |
| I_O | Output current | | 20 | mA |
| P_D | Power dissipation | | 1 | W |

1. Soldering temperature of the IC leads is to not exceed 260 °C for 10 seconds. Furthermore, the devices shall not be exposed to IR reflow nor preheat cycles (as performed as part of wave soldering). ST recommends the devices be hand-soldered or placed in sockets to avoid heat damage to the batteries.

Caution: *Negative undershoots below -0.3 V are not allowed on any pin while in the battery backup mode.*

4 DC and AC parameters

This section summarizes the operating and measurement conditions, as well as the DC and AC characteristics of the device. The parameters in the following DC and AC characteristic tables are derived from tests performed under the measurement conditions listed in [Table 6: Operating and AC measurement conditions](#). Designers should check that the operating conditions in their projects match the measurement conditions when using the quoted parameters.

- Valid for ambient operating temperature: $T_A = 0$ to 70 °C; $V_{CC} = 4.75$ to 5.5 V or 4.5 to 5.5 V (except where noted).
- Outputs deselected.

Figure 10. Power down/up mode AC waveforms

Note: *Inputs may or may not be recognized at this time. Caution should be taken to keep \bar{E} high as V_{CC} rises past $V_{PFD} (min)$. Some systems may perform inadvertent WRITE cycles after V_{CC} rises above $V_{PFD} (min)$ but before normal system operations begin. Even though a power on reset is being applied to the processor, a reset condition may not occur until after the system is running.*

| t_{REC} | \overline{E} or \overline{W} at V_{IH} after power up | 2 | - | ms |

- Valid for ambient operating temperature: $T_A = 0$ to 70 °C; $V_{CC} = 4.75$ to 5.5 V or 4.5 to 5.5 V (except where noted).
- V_{PFD} (max) to V_{PFD} (min) fall time of less than t_F may result in deselection/write protection not occurring until $200 \mu s$ after V_{CC} passes V_{PFD} (min).
- V_{PFD} (min) to V_{SS} fall time of less than t_{FB} may cause corruption of RAM data.
