Atmel ATA6833/ATA6834

BLDC Motor Driver and LIN System Basis Chip

DATASHEET

Features

- Atmel ATA6833 temperature range T_J = 150°C
- Atmel ATA6834 extended temperature range T_J = 200°C
- Direct driving of 6 external NMOS transistors with a maximum switching frequency of 50kHz
- Integrated charge pump to provide gate voltages for high-side drivers and to supply the gate of the external battery reverse protection NMOS
- Built-in 5V/3.3V voltage regulator with current limitation
- Reset signal for the microcontroller
- Sleep Mode with supply current of typically < 45µA
- Wake-up via LIN bus or high voltage input
- Programmable window watchdog
- Battery overvoltage protection and battery undervoltage management
- Overtemperature warning and protection (shutdown)
- 200mA peak current for each output driver
- LIN transceiver conformal to LIN 2.1 and SAEJ2602-2 with outstanding EMC and ESD performance
- QFN48 package 7mm × 7mm

1. Description

The Atmel® ATA6833 and Atmel ATA6834 are system basis chips for three-phase brushless DC motor controllers designed in Atmel's state-of-the-art 0.8µm SOI technology SMART-I.S.™1. In combination with a microcontroller and six discrete power MOSFETs, the system basis chip forms a BLDC motor control unit for automotive applications. In addition, the circuits provide a 3.3V/5V linear regulator and a window watchdog.

The circuit includes various control and protection functions like overvoltage and overtemperature protection, short circuit detection, and undervoltage management. Thanks to these function blocks, the driver fulfils a maximum of safety requirements and offers a high integration level to save cost and space in various applications. The target applications are most suitable for the automotive market due to the robust technology and the high qualification level. Atmel ATA6834, in particular, is designed for applications in a high-temperature environment.

41	L2	O	Gate voltage H-bridge, low-side 2
42	L3	O	Gate voltage H-bridge, low-side 3
43	PGND	I	Power ground for H-bridge and charge pump
44	VCC	O	5V/100mA supply for microcontroller
45	NC		Connect to GND
46	VBAT	I	Supply voltage for IC core (after reverse protection)
47	EN2	I	High voltage enable input
48	VBATSW	O	100Ω PMOS switch from V_{BAT}

3. Functional Description

3.1 Power Supply Unit with Supervisor Functions

3.1.1 Power Supply

The IC has to be supplied by a reverse-protected battery voltage. To prevent damage to the IC, proper external protection circuitry has to be added. It is recommended to use at least one capacitor combination of storage and RF capacitors behind the reverse protection circuitry, which is connected close to the VBAT and GND pins of the IC.

A fully integrated low-power and low-drop regulator (VINT regulator), stabilized by an external blocking capacitor, provides the necessary low-voltage supply needed for the wake-up process. A trimmed low-power band gap is used as reference for the VINT regulator as well as for the VCC regulator. All internal blocks are supplied by VINT regulator. VINT regulator must not be used for any external supply purposes.

Nothing inside the IC except the logic interface to the external microcontroller is supplied by the 5V/3.3V VCC regulator.

Both voltage regulators are checked by a “power-good comparator”, which keeps the whole chip in reset as long as the internal supply voltage (VINT regulator output) is too low and generates a reset for the external microcontroller if the output voltage of the VCC regulator is not sufficient.

3.1.2 VBatt Switch

This high-voltage switch provides the battery voltage at pin VBATSW for various purposes. It is switched ON after power on reset when the IC transits to Active Mode and it will only turn OFF when the IC changes to Sleep Mode. Watchdog resets do not have an effect on the switch. The switch can be used for measuring purposes as well as to switch on external voltage regulators.

3.1.3 Voltage Supervisor

This function is implemented to protect the IC and the external power MOS transistors from damage due to overvoltage on PBAT input. In the event of overvoltage (V_{THOV}) or undervoltage (V_{THUV}), the external NMOS motor driver transistors will be switched off. The failure state will be flagged on DG2 pin. It is recommended to block PBAT with an external RF capacitor to suppress high frequency disturbances.

3.1.4 Temperature Supervisor

An integrated temperature sensor prevents the IC from overheating. If the temperature is above the overtemperature pre-warning threshold $T_{JPW\ set}$, the diagnostic pin DG3 will be switched to HIGH to signal this event to the external microcontroller. The microcontroller should take actions to reduce the power dissipation in the IC. If the temperature rises above the overtemperature shutdown threshold $T_{J\ switch\ off}$, the VCC regulator and all output drivers together with the LIN transceiver will be switched OFF immediately and the /RESET signal will go LOW. Both thresholds have a built-in hysteresis to avoid oscillations. The IC will return to normal operation (Active Mode) when it has cooled down below the shutdown threshold. When the junction temperature drops below the pre-warning threshold, bit DG3 will be switched LOW.

3.2 Active Mode and Sleep Mode

The IC has two modes: Sleep Mode and Active Mode. Switching between the modes is described below. By default the IC starts in Active Mode (which means normal operation) after power-on. A *Go to Sleep* procedure switches the IC from Active Mode to Sleep Mode (standby). A *Go to Active* procedure brings the IC back from Sleep Mode to Active Mode. When in Sleep Mode the internal 5V supply (VINT regulator), the EN2 pin input structure, and a certain part of the LIN receiver remain active to ensure a proper startup of the system. The VCC regulator is turned off.

The *Go to Sleep* and *Go to Active* procedures are implemented as follows:

Go to Sleep

Pin EN1 is a low-voltage input supplied by the VCC regulator. It is ESD protected by diodes against VCC and GND. Thus the input voltage at pin EN1 must not go below GND or exceed the output voltage of the VCC regulator. A transition from HIGH to LOW followed by a permanent LOW signal for a minimum time period $t_{gotosleep}$ (typical 10µs) at pin EN1 switches the IC to Sleep Mode as the EN1 is edge triggered. V_{CC} is switched off in Sleep Mode. It is recommended to keep EN1 LOW during normal operation.

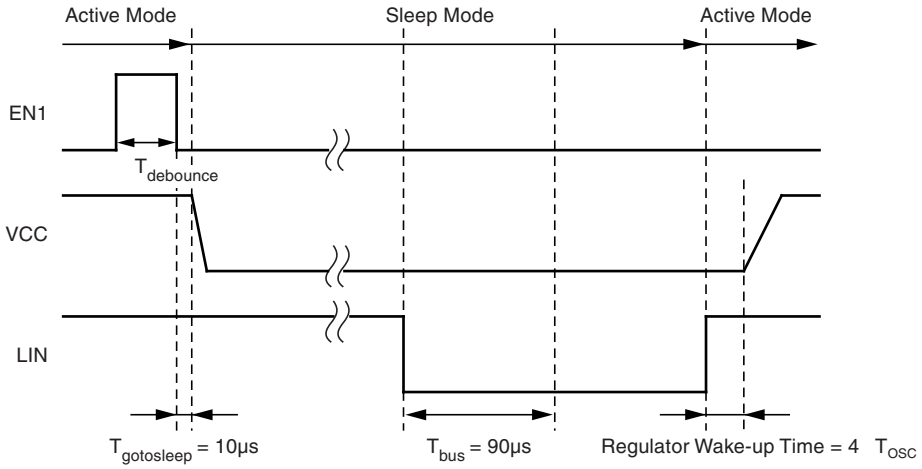
Go to Active Using Pin EN2

Pin EN2 is a high-voltage input for external wake-up signals. Its input structure consists of a comparator with a built-in hysteresis. It is ESD-protected by diodes against GND and V_{BAT}, B, and for this reason the applied input voltage must not go below GND or exceed V_{BAT}. Pulling EN2 up to V_{BAT} switches the IC to Active Mode. EN2 is debounced and edge triggered.

Go to Active Using the LIN Interface

Using the LIN interface provides a second possibility to wake-up the IC (see Figure 3-1). A falling edge at pin LIN followed by a dominant bus level maintained for a minimum time period (T_{bus}) and ending with a rising edge leads to a remote wake-up request. The device switches from Sleep Mode to Active Mode. The VCC regulator is activated and the internal LIN slave termination resistor is switched on.

Figure 3-1. Wake-up Using the LIN Interface



3.3 5V/3.3V VCC Regulator

The 5V/3.3V regulator is fully integrated. It requires an external electrolytic capacitor in the range of 2.2µF up to 10µF and with an ESR in the range from 2Ω to 15Ω for stability (see Figure 3-2). The output voltage can be configured as either 5V or 3.3V by connecting pin VMODE to either pin VINT or GND. Since the regulator is not designed to be switched between both output voltages during operation, it is advisable to hard-wire VMODE pin. The logic levels of the microcontroller interface are adapted to the VCC regulator output voltage. The maximum output current (I_{OS1}) of the regulator is 100mA. For T_J > 150°C the I_{OS1} of Atmel® ATA6834 is reduced to 80mA. The VCC regulator has a built-in short circuit protection. A comparator checks the output voltage of the VCC regulator and keeps the external microcontroller in reset as long as the voltage is below the lower operation minimum (shown in Figure 3-3).

Figure 3-2. ESR versus Load Current for External Capacitors with Different Values

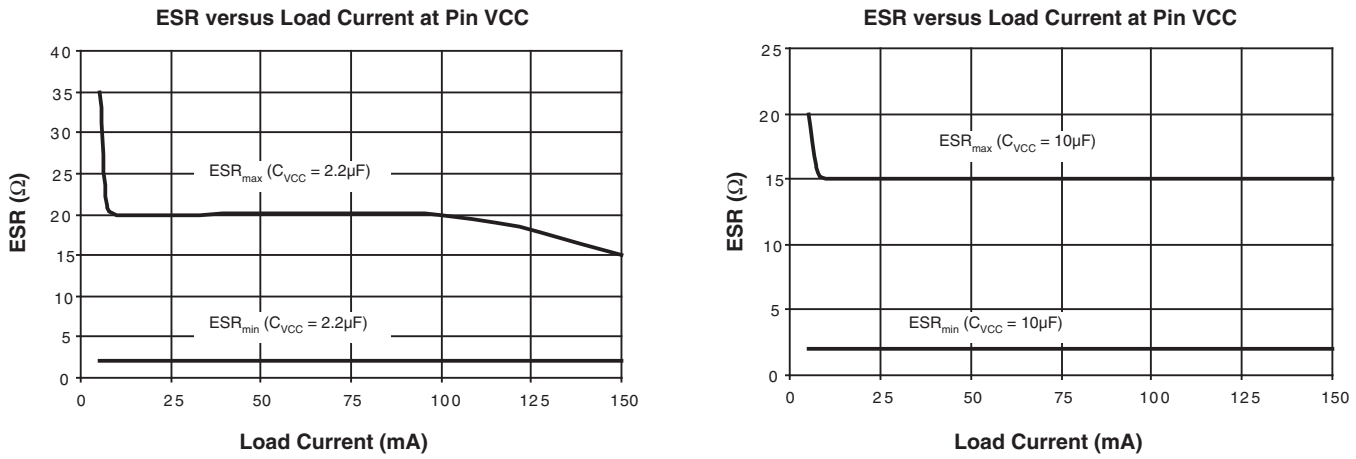


Figure 3-3. /RESET as Function of the VCC Output Voltage

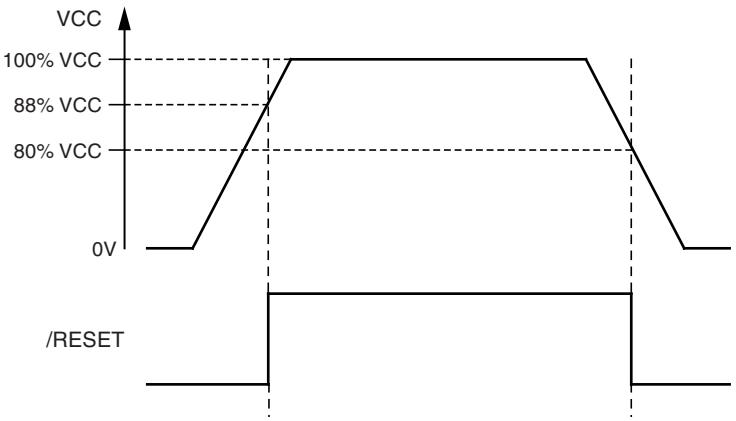
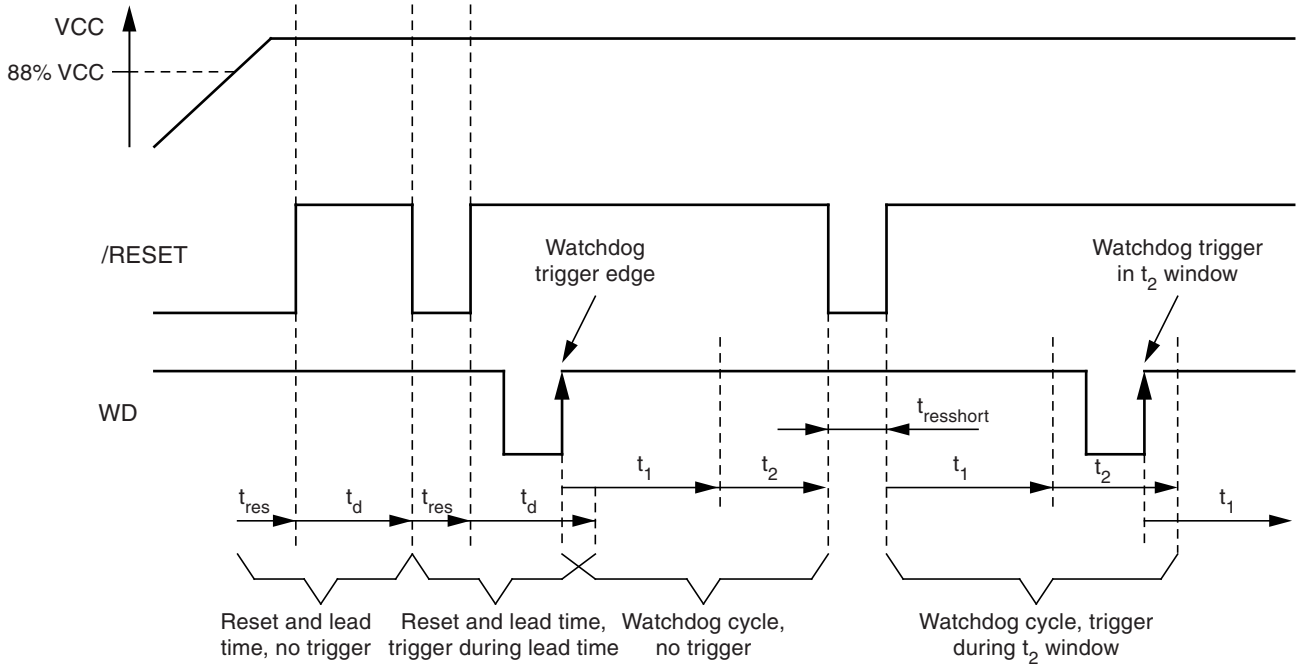


3.4 Reset and Watchdog Management

The watchdog timing is based on the trimmed internal watchdog oscillator. Its period time T_{OSC} is determined by the external resistor R_{WD}. A HIGH signal on WDD pin enables the watchdog function; a LOW signal disables it. Since WDD pin is equipped with an internal pull-up resistor the watchdog is enabled by default. In order to keep the current consumption as low as possible the watchdog is switched off during Sleep Mode.

The timing diagram in Figure 3-4 shows the watchdog and external reset timing.

Figure 3-4. Timing Diagram of the Watchdog in Conjunction with the /RESET Signal



After power-up of the VCC regulator (VCC output exceeds 88% of its nominal value) /RESET output stays LOW for the timeout period t_{res} (typical 10ms). Subsequently /RESET output switches to HIGH. During the following time t_d (typical 500ms) a rising edge at the input WD is expected otherwise another external reset will be triggered.

When the watchdog has been correctly triggered for the first time, normal watch-dog operation begins. A normal watchdog cycle consists of two time sections t_1 and t_2 followed by a short pulse for the time $t_{resshort}$ at /RESET if no valid trigger has been applied at pin WD during t_2. Rising edges on WD pin during t_1 also cause a short pulse on /RESET. Start for such a cycle is always the time of the last rising edge either on WD pin or on /RESET pin.

If the watchdog is disabled (WDD = LOW), only the initial reset for the time t_{res} after power-up will be generated.

Additional resets will be generated if the VCC output voltage drops below 80% of its nominal value.

The following example demonstrates how to calculate the timing scheme for valid watchdog trigger pulses, which the external microcontroller has to provide in order to prevent undesired resets.

Example:

Using an external resistor R_{WD} = 33 kΩ ±1% results in typical parameters as follows:

T_{OSC} = 12.4µs

$t_1 = 980 \times T_{OSC}$ = 12.1ms ±10%

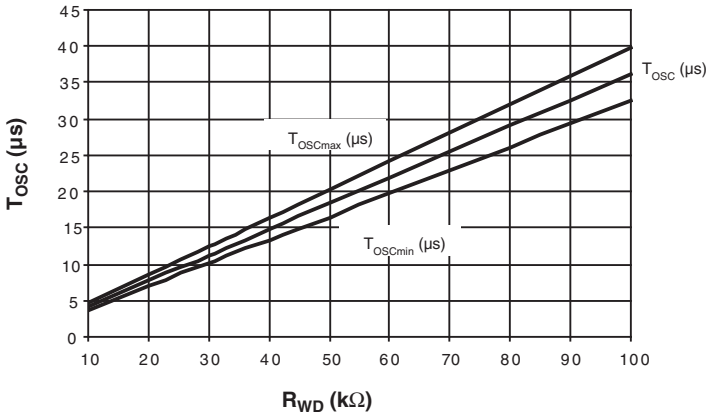
$t_2 = 780 \times T_{OSC}$ = 9.6ms ±10%

$t_1 + t_2$ = 21.7ms ±10%

Hence, the minimum time the external microcontroller has to wait before pin WD can be triggered is in worst case $t_{min} = 1.1 \times t_1$ = 13.3ms. The maximum time for the watchdog trigger on WD pin is $t_{max} = 0.9 \times (t_1 + t_2)$ = 19.5ms. Thus watchdog trigger input must remain within $t_{max} - t_{min}$ = 6.2ms.

Other values can be set up by picking a different resistor value for R_{WD}. The dependency of T_{OSC} on the value of R_{WD} is shown in Figure 3-5.

Figure 3-5. T_{OSC} versus R_{WD}



The tolerance of T_{OSC} is ±10% for resistors R_{WD} with maximum ±1% in tolerance.

3.5 Charge Pump

A charge pump has been implemented in order to provide sufficient voltage to operate the external high-side power-NMOS transistors and the VG regulator, which drives the low-side Power-NMOS transistors. The charge pump output voltage at CPOUT pin is controlled to settle typically about 15V above the voltage at pin PBAT. A built-in supervisor circuit checks if the output voltage is sufficient to operate the VG regulator and external Power-NMOS transistors. The output voltage is accepted as good when it rises above VCP_{CPGOOD}. A charge pump failure is flagged at DG2 if this minimum can not be reached or if the output voltage drops below the lower threshold of VCP_{CPGOOD} due to overloading.

The two shuffle capacitors should have the same value. The value of the reservoir capacitor should be at least twice the value of one shuffle capacitor. Two external shuffle capacitors and an external reservoir capacitor have to be provided. The typical values for the two shuffle capacitor is 100nF, and for the reservoir capacitor is 470nF. All capacitors should be ceramic. It is advisable to pick a reservoir capacitor with twice or three-times the size of the two equally-sized shuffle capacitors. The greater the capacitors, the greater the output current capability.

3.6 VG Regulator

The VG regulator provides a stable voltage to supply the low-side gate drivers and to deliver sufficient voltage for the external low-side Power-NMOS transistors. Typically the output voltage is 12V. In order to guarantee reliable operation even with a low battery voltage, the VG regulator is supplied by the charge pump output. For stability, an external ceramic capacitor of typically 470nF has to be provided. There is no internal supervision of the VG output voltage.

3.7 Output Drivers and Control Inputs IL1-IL3, IH1-IH3

This IC offers six push-pull output drivers for the external low-side and high-side power-NMOS transistors. To guarantee reliable operation, the low-side drivers are supplied by the VG regulator while the high-side drivers are supplied directly by the charge pump. All drivers are designed to operate at switching frequencies in the range of DC up to 50kHz. The maximum gate charge that can be delivered to each external Power-NMOS transistor at 50kHz is 100nC.

The output drivers are directly controlled by the digital input pins IL1 to IL3 and IH1 to IH3 (see Table 3-1). All pins are equipped with an internal pull-down resistor. To operate the output drivers properly the following requirements have to be fulfilled:

1. Device is in Active Mode.
2. In case of watchdog is enabled, at least one valid watchdog trigger has been accepted.
3. The voltage at pin PBAT lies within its operation range. Neither undervoltage nor overvoltage is present.
4. The charge pump output voltage has been accepted as good, thus it exceeded VCP_{CPGOOD}.
5. No overtemperature shutdown has occurred.

If a short circuit is detected by one of the sense inputs S1 to S3, the output drivers will be switched off after a debounce time of 6 µs and the output DG1 will be flagged (see also Section 3.8 “Short Circuit Detection” on page 10). The output drivers will be enabled again and DG1 will be cleared with a rising edge at one of the control inputs (IL1 to IL3, IH1 to IH3).

Additional logic prevents short circuits due to switching on one power-NMOS transistor while the opposite one in the same branch is switched on already.

Table 3-1. Status of the Output Drivers Depending on the Control Inputs

Mode	Control Inputs IL(1..3)	Control Inputs IH(1..3)	Driver Stage for External Power MOS L(1..3), H(1..3)	Comments
Sleep	X	X	OFF	Sleep Mode
Active	0	0	OFF	
Active	1	0	L(1..3) ON, H(1..3) OFF	
Active	0	1	H(1..3) ON, L(1..3) OFF	
Active	1	1	OFF	Shoot-through protection

3.8 Short Circuit Detection

Short circuits in the motor bridge circuitry are sensed by S1 to S3 inputs. Internal comparators monitor the voltage differences between the drain and the source terminals of the external power-NMOS transistors. If one transistor switches on and its drain-source voltage exceeds V_{SC} threshold (typically 4V) after a blanking time t_{SC} (typically 6µs, see Figure 3-6), a short circuit in this branch will be detected. In this case, all output drivers will be switched off immediately and pin DG1 will be set to HIGH. With a rising edge at any of the pins IL1 to IL3 or IH1 to IH3, the diagnostic output DG1will be reset and the drivers can be switched on again.

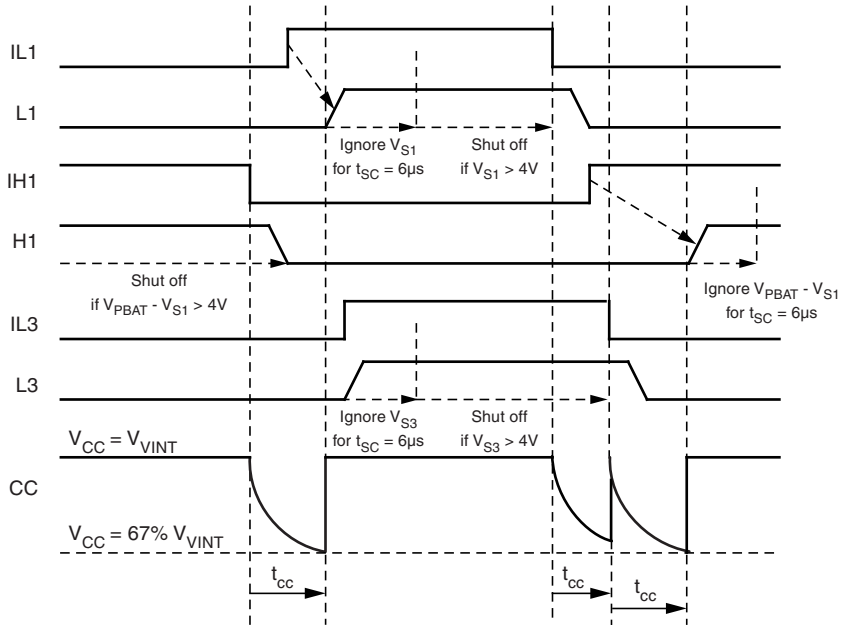
3.9 Cross Conduction Timer

In order to prevent damage of the motor bridge due to peak currents a non-overlapping phase for switching the power-NMOS transistors is mandatory. Therefore, a cross conduction timer has been implemented to prevent switching on any output driver for a time t_{CC} after any other driver has been switched off. This also accounts for toggling any other driver after a short circuit was detected. An external RC parallel combination defines the value for t_{CC} and can be estimated as follows:

$t_{CC} = K_{CC} \times R_{CC}$ (kΩ) $\times C_{CC}$ (nF), K_{CC} is specified in Section 8. “Electrical Characteristics” on page 15.

The RC combination is connected between CC and GND pins. When one of the drivers has been switched off the RC combination is charged to 5V (VINT) and discharged with its time constant. Any low to high transition at the control inputs will be masked out at the driver outputs until the voltage at CC pin drops below 67% of its initial value (VINT). The timer will be re-triggered at any time by any falling edge at the control inputs. This is shown in the following figure.

Figure 3-6. Interaction of Short Circuit Detection and Cross Conduction Timer



At least 5kW minimum and 5nF at maximum should be used as values for the RC combination. 10kW is recommended. If the non-overlapping phase is controlled by the external microcontroller, it is possible to do without the external capacitor. The minimum time t_{CC} is defined by the parasitic capacitance at CC pin.

3.10 Diagnostic Outputs D1 - D3

As mentioned in the sections above, the diagnostic outputs DG1 to DG3 are used to signal failures. This is summarized in the following table.

Note: This is only valid for VCC > $V_{tHRESHLow}$. Otherwise all diagnostic outputs will be tristated.

Table 3-2. Status of the Diagnostic Outputs (Normal Operation)

Device Status					Diagnostic Outputs			Comments
CPOK	OT1	OV	UV	SC	DG1	DG2	DG3	
0	X	X	X	X	–	1	–	Charge pump failure
X	1	X	X	X	–	–	1	Overtemperature prewarning
X	X	1	X	X	–	1	–	Overvoltage
X	X	X	1	X	–	1	–	Undervoltage
X	X	X	X	1	1	–	–	Short circuit

Note: X represents: no effect)
OT1: overtemperature warning
OV: overvoltage of PBAT
UV: undervoltage of PBAT
SC: short circuit
CPOK: charge pump OK

In order to differentiate between LIN and EN2 wake-up, DG1 output will be set to LOW or HIGH respectively. LOW indicates wake-up by LIN, HIGH indicates wake-up by EN2. DG1 output will be cleared by the first valid watchdog trigger after wake-up or by the first rising edge at one of the control inputs (IL1 to IL3 and IH1 toIH3) if the watchdog is disabled.

Table 3-3. Indicating Wake-up Source

Diagnostic Outputs			Wake-up Source
DG1	DG2	DG3	
1	–	–	EN2
0	–	–	LIN

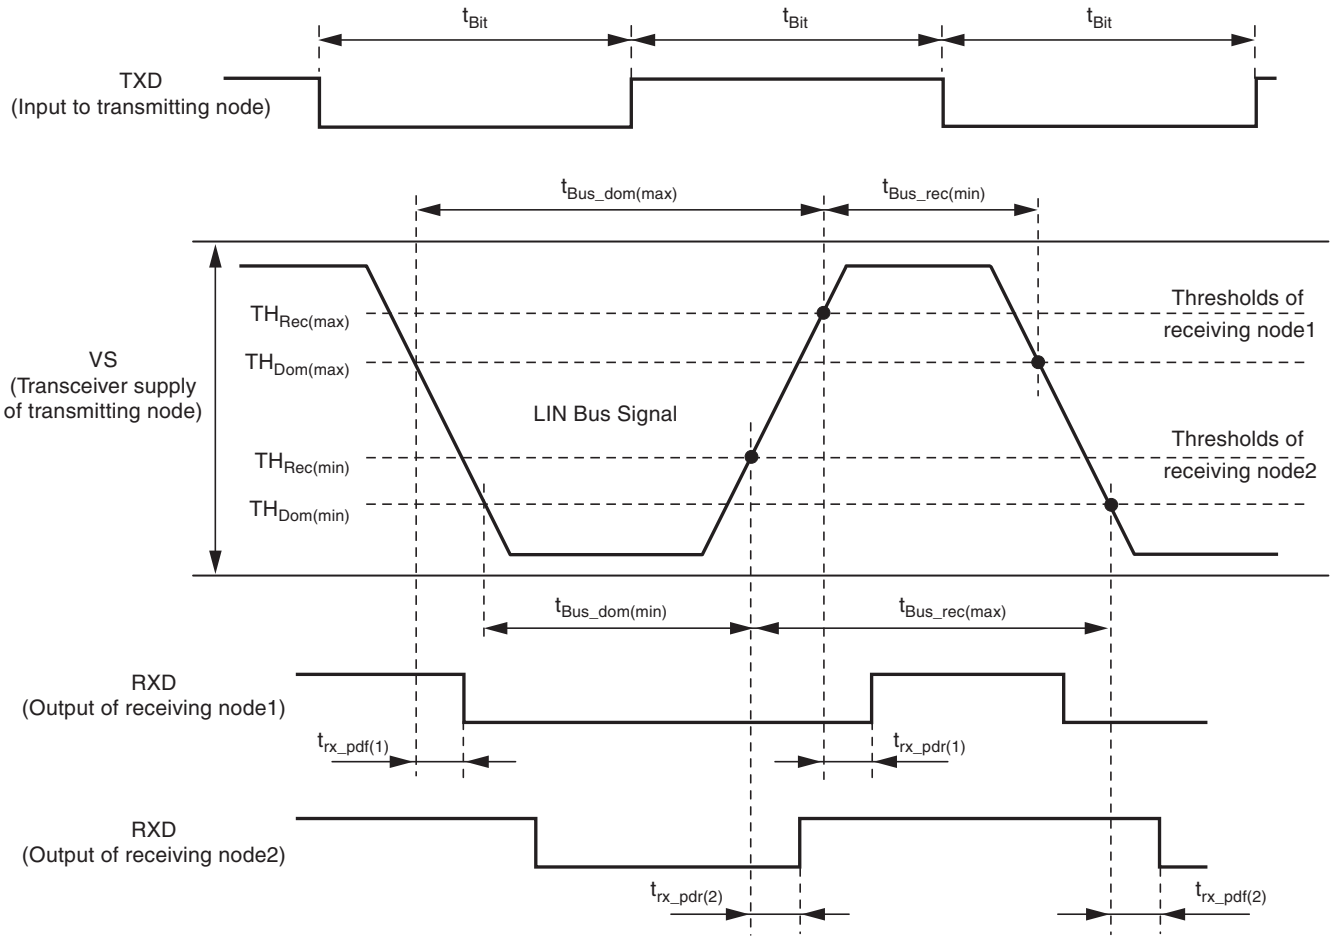
3.11 LIN Transceiver

Atmel® ATA6833 and Atmel ATA6834 include a fully integrated LIN transceiver complying with LIN specification 2.1 and SAEJ2602 2. The transceiver consists of a low-side driver with slew rate control, wave shaping, current limiting, and a high voltage comparator followed by a debouncing unit in the receiver.

During transmission, the data applied at pin TXD will be transferred to the bus driver to generate a bus signal on LIN pin. TXD input has an internal pull-up resistor.

To minimize the electromagnetic emission of the bus line, the bus driver has a built-in slew rate control and wave-shaping unit. The transmission will be aborted by a thermal shutdown or by a transition to Sleep Mode.

Figure 3-7. Definition of Bus Timing Parameters



The recessive BUS level is generated from the integrated 30kΩ pull-up resistor in series with an active diode. This diode protects against reverse currents on the bus line in case of a voltage difference between the bus line and VSUP ($V_{BUS} > V_{SUP}$). No additional termination resistor is necessary to use the IC as a LIN slave. If this IC is used as a LIN master, the LIN pin is terminated by an external 1kΩ resistor in series with a diode to VBAT.

As PWM communication directly over the LIN transceiver in both directions is possible, there is no TXD timeout feature implemented in the LIN transceiver.

4. Absolute Maximum Ratings

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

All voltages are referenced to pin GND. (xxx) Values for the Atmel® ATA6834.

Parameters	Pin	Symbol	Min.	Max.	Unit
Input voltage	PGND	V_{PGND}	–0.3	+0.3	V
Negative input current	VBAT	IVBAT	–15		mA
Negative input current	PBAT	IPBAT	–20		mA
Supply voltage	VBAT	V_{VBAT}		+40	V
Supply voltage	PBAT	V_{PBAT}		+40	V
Logic output voltage	/RESET, DG1, DG2, DG3, RXD	$V_{/RESET}$, V_{DG1}, V_{DG2}, V_{DG3}, V_{RXD}	–0.3	V_{VCC} + 0.3	V
Logic input voltage	IL1-3, IH1-3, WD, WDD, EN1, TXD	V_{IL1-3}, V_{IH1-3}, V_{WD}, V_{EN1}, V_{TXD}	–0.3	V_{VCC} + 0.3	V

	Lx, Hx	I_{Lx_R}, I_{Hx_R}	–1		mA

Note: Estimated values take T_J > 150°C into account.

5. Thermal Resistance

Parameters	Symbol	Value	Unit
Thermal resistance junction to heat slug	R_{thjc}	< 5	K/W
Thermal resistance junction to ambient when heat slug is soldered to PCB	R_{thja}	25	K/W

6. Operating Range

The operating conditions define the limits for functional operation and parametric characteristics of the device. Functionality outside these limits is not implied unless otherwise stated explicitly. (xxx) Values for the Atmel® ATA6834

Parameters	Symbol	Min	Max	Unit
Operating supply voltage(1)	V_{VBAT}	5.5	V_{THOV}(4)	V
Operating supply voltage(2)	V_{VBAT}	4.3	5.5	V
Operating supply voltage(3)	V_{VBAT}	V_{THOV}	40	V
Ambient temperature range	T_A	–40	+150	°C
Junction temperature range	T_J	–40	+150 (200)	°C

Notes: 1. Full functionality
2. Output drivers are switched off, extended range for parameters for voltage regulators
3. Output drivers and charge pump are switched off

7. Noise and Surge Immunity, ESD and Latch-up

Parameters	Standard and Test Conditions	Value
Conducted interferences	ISO 7637-1	Level 4(1)
Conducted disturbances	CISP25	Level 5
ESD according to IBEE LIN EMC - Pins LIN, PBAT, VBAT - Pin EN2 (33kΩ serial resistor)	Test specification 1.0 following IEC 61000-4-2	 ±6 kV ±5 kV
ESD HBM with 1.5kΩ/100pF	ESD- STM5.1-2001 JESD22-A114E 2007 CEI/IEC 60749-26: 2006 AEC-Q100-002-Ref_D	±2 kV
ESD HBM with 1.5kΩ/100pF Pins EN2, LIN, PBAT, VBAT against GND	ESD- STM5.1-2001 JESD22-A114E 2007 CEI/IEC 60749-26: 2006 AEC-Q100-002-Ref_D	±8 kV
ESD CDM (field induced method)	ESD STM5.3.1 - 1999	±500V

Note: 1. Test pulse 5: $V_{bat\ max}$ = 40V

Static latch-up tested according to AEC-Q100-004 and JESD78.

- 3 to 6 samples, 0 failures
- Electrical post-stress testing at room temperature

In test, the voltage at the pins VBAT, LIN, CP, VBATSW, Hx, and Sx must not exceed 45V when not able to drive the specified current.

8. Electrical Characteristics

All parameters given are valid for 5.5V ≤ V_{VBAT} ≤ 18V and for –40°C ≤ T_J ≤ 150°C (200°C) unless stated otherwise. All values refer to PIN GND. (xxx) Values for the Atmel® ATA6834.

No.	Parameters	Test Conditions	Pin	Symbol	Min.	Typ.	Max.	Unit	Type*

9. Application

This section describes the principal application for which the ATA6833/ATA6834 was designed.

Figure 9-1. Typical Application

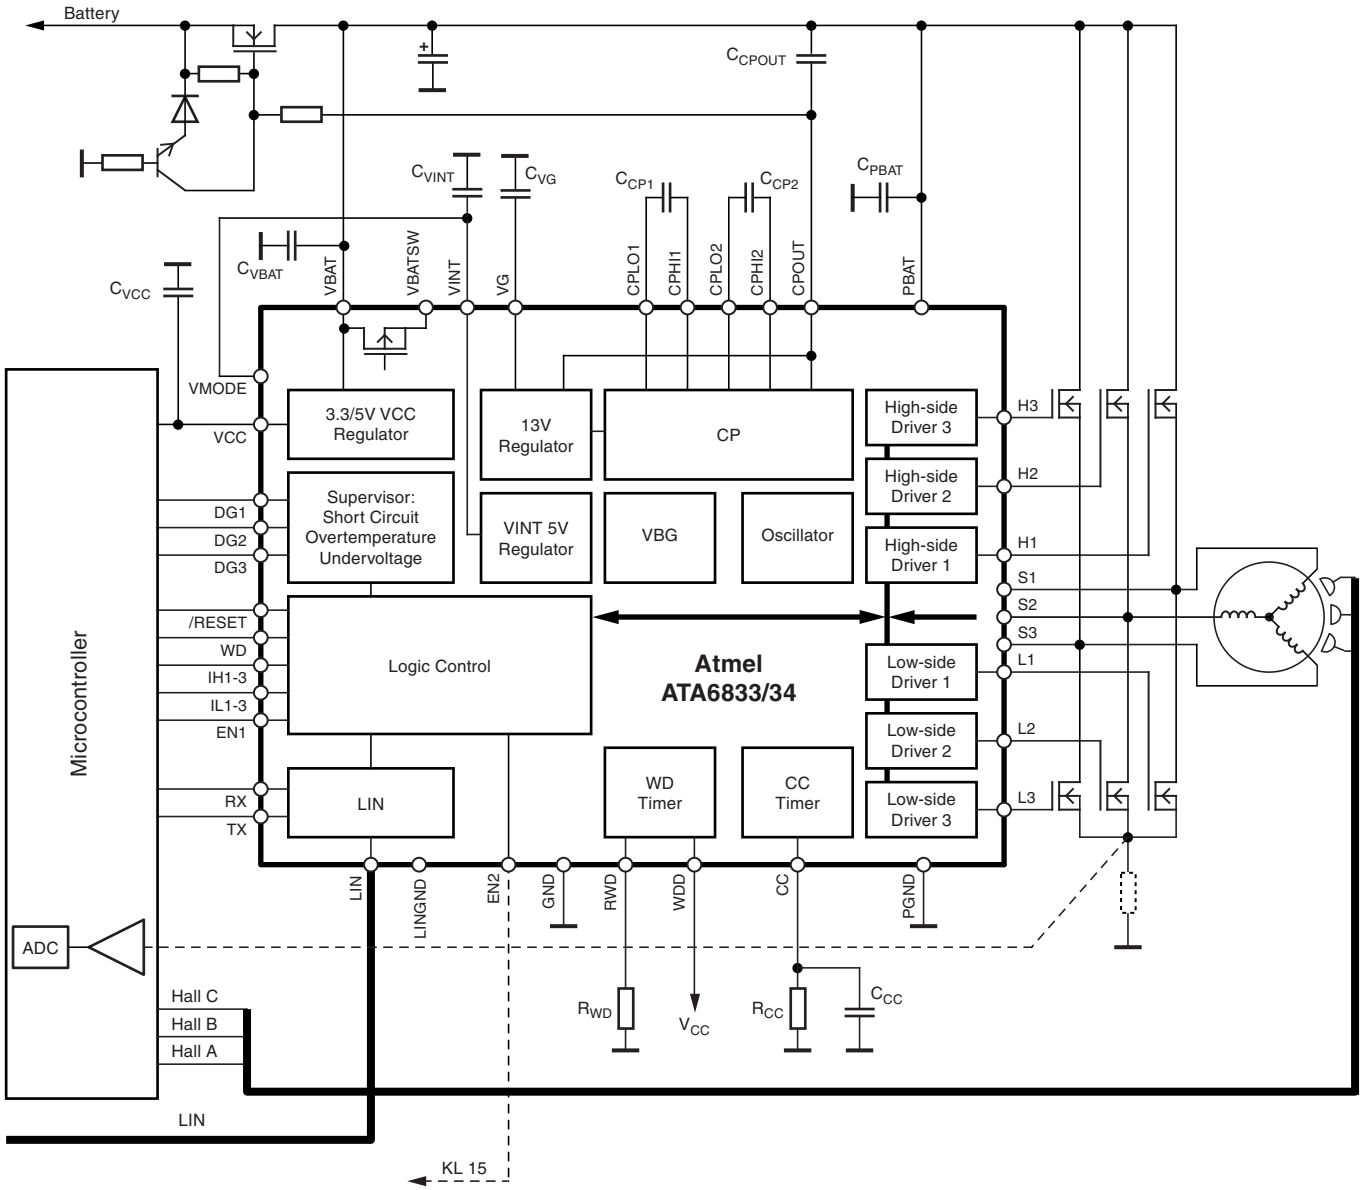

Table 9-1. Typical External Components

Component	Function	Min.	Typical	Max.
CVINT	Blocking capacitor at VINT	100nF	220nF/10V	470nF
C_{VCC}	Blocking capacitor at VCC	1.5µF		10µF
ESL (C_{VCC})	Serial inductance to C_{VCC} including PCB	1nH		20nH
ESR (C_{VCC})	Serial resistance to C_{VCC} including PCB	2Ω		15Ω
CVG	Blocking capacitor at VG	220nF	470nF, 25V	1µF
CCP1	Charge pump shuffle capacitor	47nF	220nF/25V	470nF
CCP2	Charge pump shuffle capacitor	47nF	220nF/25V	470nF
CCPOUT	Charge pump reservoir capacitor	220nF	470nF, 25V	1µF
RRWD	Resistor defining internal bias currents for watchdog oscillator	10kΩ	33kΩ	91kΩ
RCC	Cross conduction time definition resistor	5kΩ	10kΩ	
CCC	Cross conduction time definition capacitor		330pF	5nF
C_{VBAT}	Blocking capacitor VBAT		100nF	
C_{PBAT}	Blocking capacitor PBAT		100nF	

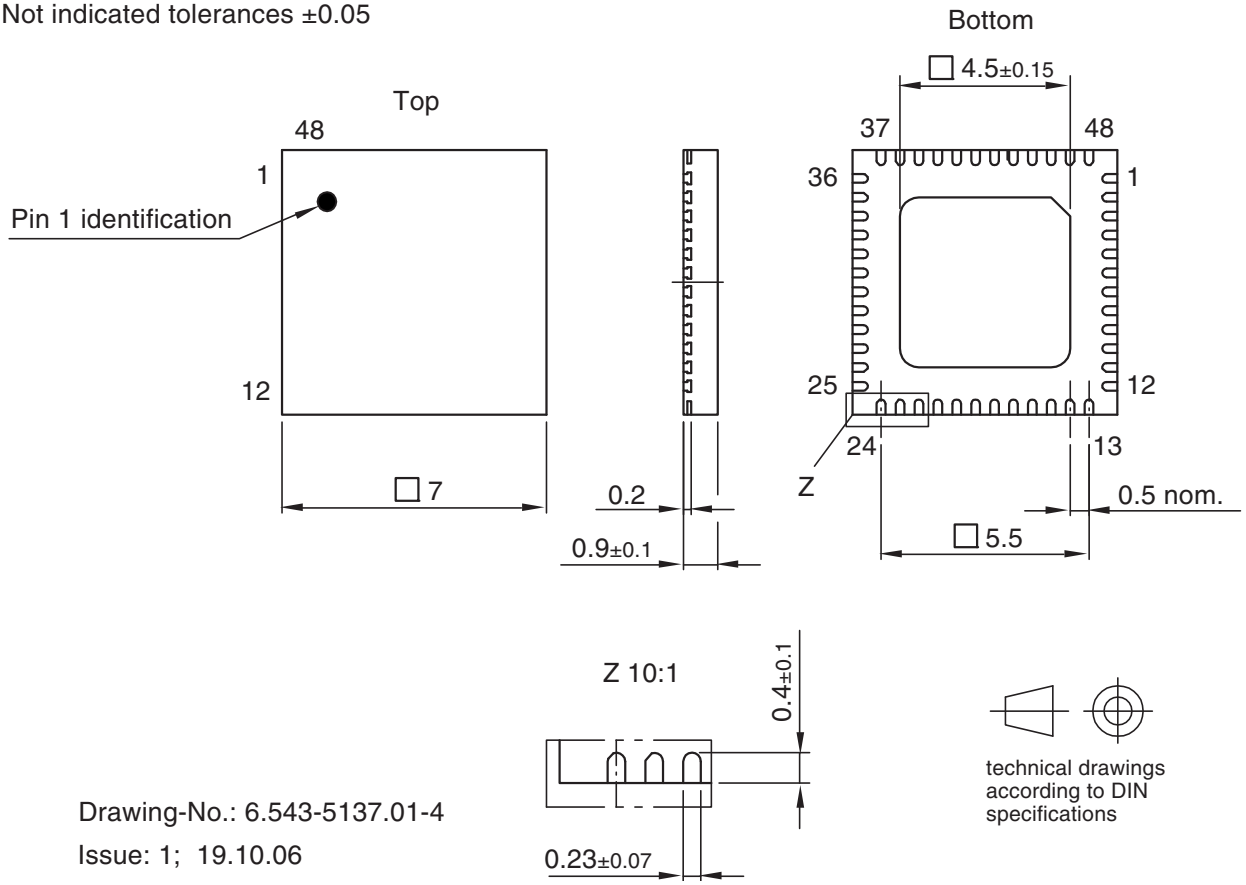
10. Ordering Information

Extended Type Number	Package	Remarks
ATA6833-PLQW	QFN48	
ATA6834-PLQW	QFN48	

11. Package Information

Package: VQFN_7 x 7_48L
Exposed pad 4.5 x 4.5
Dimensions in mm

Not indicated tolerances ±0.05



Drawing-No.: 6.543-5137.01-4
Issue: 1; 19.10.06

technical drawings
according to DIN
specifications

12. Revision History

Please note that the following page numbers referred to in this section refer to the specific revision mentioned, not to this document.

Revision No.	History
9122I-AUTO-03/12	• Section 4 “Absolute Maximum Ratings” on page 13 changed
9122H-AUTO-08/11	• Page 9: Example test changed and text under figure 3-5 added • El. Characteristics table, page 17, row 3.8 changed • El. Characteristics table, page 22, row 8.27 changed • Page 23: Typ. Application drawing changed • Page 24: Table 9-1 rows C_{VBAT} and C_{PBAT} added
9122G-AUTO-10/10	• Section 8 “Electrical Characteristics” numbers 8.23 and 8.24 on page 21 changed
9122E-AUTO-02/10	• Page 12: Note added • Page 21: El. Char. Table: rows 8.11 and 8.12 changed
9122D-AUTO-09/09	• Section 4 “Absolute Maximum Ratings” on page 14 changed • Section 8 “Electrical Characteristics” numbers 2.7, 2.8, 3.1, 3.2, 4.20, 4.21, 6.4, 8.19, 8.20, 8.23, 8.24 and 8.27 on pages 16 to 22 changed
9122C-AUTO-04/09	• Features on page 1 changed • Section 7 “Noise and Surge Immunity, ESD and Latch-up” on page 15 changed
9122B-AUTO-10/08	• Put datasheet in the latest template • Section 8 “Electrical Characteristics” on pages 15 to 21 changed
