

## ISL6527, ISL6527A

Single Synchronous Buck Pulse-Width Modulation (PWM) Controller

FN9056  
Rev 11.00  
Sep 29, 2015

The ISL6527, ISL6527A make simple work out of implementing a complete control and protection scheme for a DC/DC step-down converter. Designed to drive N-Channel MOSFETs in a synchronous buck topology, the ISL6527, ISL6527A integrate the control, output adjustment, monitoring and protection functions into a single package.

The ISL6527, ISL6527A provide simple, single feedback loop, voltage-mode control with fast transient response. The output voltage can be regulated to as low as the provided external reference. A fixed frequency oscillator reduces design complexity, while balancing typical application cost and efficiency.

The error amplifier features a 15MHz gain-bandwidth product and 6V/ $\mu$ s slew rate, which enables high converter bandwidth for fast transient performance. The resulting PWM duty cycles range from 0% to 100%.

Protection from overcurrent conditions is provided by monitoring the  $r_{DS(ON)}$  of the upper MOSFET to inhibit PWM operation appropriately. This approach simplifies the implementation and improves efficiency by eliminating the need for a current sense resistor.

### Features

- Operates from 3.3V to 5V Input
- Utilizes an External Reference
- Drives N-Channel MOSFETs
- Simple Single-Loop Control Design
  - Voltage-Mode PWM Control
- Fast Transient Response
  - High Bandwidth Error Amplifier
  - Full 0% to 100% Duty Cycle
- Lossless, Programmable Overcurrent Protection
  - Uses Upper MOSFET's  $r_{DS(ON)}$
- Converter Can Source and Sink Current
- Small Converter Size
  - Internal Fixed Frequency Oscillator
    - ISL6527: 300kHz
    - ISL6527A: 600kHz
- Internal Soft-Start
- 14 Ld SOIC or 16 Ld 5x5 QFN
- QFN package:
  - Compliant to JEDEC PUB95 MO-220 QFN - Quad Flat No Leads - Package Outline
  - Near Chip-Scale Package Footprint, which Improves PCB Efficiency and has a Thinner Profile
- Pb-Free (RoHS compliant)

### Applications

- Power Supplies for Microprocessors
  - PCs
  - Embedded Controllers
- Subsystem Power Supplies
  - PCI/AGP/GTL+ Busses
  - ACPI Power Control
  - DDR SDRAM Bus Termination Supply
- Cable Modems, Set-Top Boxes, and DSL Modems
- DSP and Core Communications Processor Supplies
- Memory Supplies
- Personal Computer Peripherals
- Industrial Power Supplies
- 3.3V Input DC/DC Regulators
- Low Voltage Distributed Power Supplies

## Ordering Information

PART NUMBER (Note)	PART MARKING	TEMP RANGE (°C)	PACKAGE (Pb-Free)	PKG DWG. #
ISL6527ACBZ*	6527ACBZ	0 to +70	14 Ld SOIC	M14.15
ISL6527ACRZ* (No longer available, recommended replacement: ISL6527ACBZ, ISL6527ACBZ-T)	ISL6527 ACRZ	0 to +70	16 Ld 5x5 QFN	L16.5x5B

ISL6527AEVAL2	ISL6527A QFN Evaluation Board			

\*Add "-T" suffix for tape and reel. Please refer to TB347 for details on reel specifications.

NOTE: These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

## Pinouts

**Typical Application - 3.3V Input**

**Typical Application - 5V Input**

**Block Diagram**

## Functional Pin Description

### VCC

This pin provides the bias supply for the ISL6527, ISL6527A. Connect a well-decoupled 3.3V supply to this pin.

### COMP and FB

COMP and FB are two of the three available external pins of the error amplifier. The FB pin is the inverting input of the internal error amplifier and the COMP pin is the error amplifier output. These pins are used to compensate the voltage-control feedback loop of the converter.

### REF\_IN

This pin is the third available external pin of the error amplifier and represents the non-inverting input to the error amplifier. Connect the desired reference voltage to this pin. Voltage applied to this pin must not exceed 1.5V.

### GND

This pin represents the signal and power ground for the IC. Tie this pin to the ground island/plane through the lowest impedance connection available.

### PHASE

Connect this pin to the upper MOSFET's source. This pin is used to monitor the voltage drop across the upper MOSFET for overcurrent protection.

### UGATE

Connect this pin to the upper MOSFET's gate. This pin provides the PWM-controlled gate drive for the upper MOSFET. This pin is also monitored by the adaptive shoot-through protection circuitry to determine when the upper MOSFET has turned off.

### BOOT

This pin provides ground referenced bias voltage to the upper MOSFET driver. A bootstrap circuit is used to create a voltage suitable to drive a logic-level N-channel MOSFET.

### LGATE

Connect this pin to the lower MOSFET's gate. This pin provides the PWM-controlled gate drive for the lower MOSFET. This pin is also monitored by the adaptive shoot-through protection circuitry to determine when the lower MOSFET has turned off.

### OCSET/SD

Connect a resistor ( $R_{OCSET}$ ) from this pin to the drain of the upper MOSFET ( $V_{IN}$ ).  $R_{OCSET}$ , an internal 20 $\mu$ A current source ( $I_{OCSET}$ ), and the upper MOSFET ON-resistance ( $r_{DS(ON)}$ ) set the converter overcurrent (OC) trip point according to Equation 1:

$$I_{PEAK} = \frac{I_{OCSET} \times R_{OCSET}}{r_{DS(ON)}} \quad (\text{EQ. 1})$$

An overcurrent trip cycles the soft-start function.

Pulling OCSET/SD to a voltage level below 0.8V disables the controller. Disabling the ISL6527, ISL6527A causes the oscillator to stop, the LGATE and UGATE outputs to be held low, and the soft-start circuitry to re-arm.

### CT1 and CT2

These pins are the connections for the external charge pump capacitor. A minimum of a 0.1 $\mu$ F ceramic capacitor is recommended for proper operation of the IC.

### CPVOUT

This pin represents the output of the charge pump. The voltage at this pin is the bias voltage for the IC. Connect a decoupling capacitor from this pin to ground. The value of the decoupling capacitor should be at least 10x the value of the charge pump capacitor. This pin may be tied to the bootstrap circuit as the source for creating the BOOT voltage.

### CPGND

This pin represents the signal and power ground for the charge pump. Tie this pin to the ground island/plane through the lowest impedance connection available.

**Absolute Maximum Ratings**

Supply Voltage, VCC	+7V
Absolute Boot Voltage, V <sub>BOOT</sub>	+15.0V
Absolute Error Amplifier Input, V <sub>EA+</sub>	+1.5V
Upper Driver Supply Voltage, V <sub>BOOT</sub> - V <sub>PHASE</sub>	+7.0V
Input, Output or I/O Voltage	GND -0.3V to VCC +0.3V

**Operating Conditions**

Supply Voltage, VCC	+3.3V ±10%
Ambient Temperature Range	-40°C to +85°C
Junction Temperature Range	-40°C to +125°C

CAUTION: Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions may adversely impact product reliability and result in failures not covered by warranty.

## NOTES:

1.  $\theta_{JA}$  is measured with the component mounted on a high effective thermal conductivity test board in free air. See Tech Brief TB379 for details.
2.  $\theta_{JA}$  is measured in free air with the component mounted on a high effective thermal conductivity test board with "direct attach" features. See Tech Brief TB379.
3. For  $\theta_{JC}$ , the "case temp" location is the center of the exposed metal pad on the package underside.

**Thermal Information**

Thermal Resistance	$\theta_{JA}$ (°C/W)	$\theta_{JC}$ (°C/W)
SOIC Package (Note 1)	67	N/A
QFN Package (Notes 2, 3)	35	5
Maximum Junction Temperature	+150°C	
Maximum Storage Temperature Range	-65°C to +150°C	
Pb-free Reflow Profile	see link below

## Functional Description

### Initialization

The ISL6527, ISL6527A automatically initialize upon receipt of power. Special sequencing of the input supplies is not necessary. The Power-On Reset (POR) function continually monitors the the output voltage of the Charge Pump. During POR, the Charge Pump operates on a free running oscillator. Once the POR level is reached, the Charge Pump oscillator is synched to the PWM oscillator. The POR function also initiates the soft-start operation after the Charge Pump Output Voltage exceeds its POR threshold.

### Soft-Start

The POR function initiates the digital soft-start sequence. The PWM error amplifier reference is clamped to a level proportional to the soft-start voltage. As the soft-start voltage slews up, the PWM comparator generates PHASE pulses of increasing width that charge the output capacitor(s). This method provides a rapid and controlled output voltage rise. The soft-start sequence typically takes about 6.5ms when  $V_{REF\_IN}$  is 1.5V

If  $V_{REF\_IN}$  is less that 1.5V, the soft-start rise time will be proportionally smaller as shown in Equation 2:

$$\text{RiseTime} = t_{SS} \times \frac{V_{REFIN}}{1.5V} \quad (\text{EQ. 2})$$

Figure 1 shows the soft-start sequence for a typical application. At  $T_0$ , the +3.3V VCC voltage starts to ramp. At time  $t_1$ , the Charge Pump begins operation and the +5V CPVOUT IC bias voltage starts to ramp up. Once the voltage on CPVOUT crosses the POR threshold at time  $t_2$ , the output begins the soft-start sequence. The triangle waveform from the PWM oscillator is compared to the rising error amplifier output voltage. As the error amplifier voltage increases, the pulse-width on the UGATE pin increases to reach the steady-state duty cycle at time  $t_3$ .

FIGURE 1. SOFT-START INTERVAL

### Shoot-Through Protection

A shoot-through condition occurs when both the upper MOSFET and lower MOSFET are turned on simultaneously, effectively shorting the input voltage to ground. To protect the regulator from a shoot-through condition, the ISL6527, ISL6527A incorporate specialized circuitry, which insures that the complementary MOSFETs are not ON simultaneously.

The adaptive shoot-through protection utilized by the ISL6527, ISL6527A looks at the lower gate drive pin, LGATE, and the upper gate drive pin, UGATE, to determine whether a MOSFET is ON or OFF. If the voltage from UGATE or from LGATE to GND is less than 0.8V, then the respective MOSFET is defined as being OFF and the complementary MOSFET is turned ON. This method of shoot-through protection allows the regulator to sink or source current.

Since the voltage of the lower MOSFET gate and the upper MOSFET gate are being measured to determine the state of the MOSFET, the designer is encouraged to consider the repercussions of introducing external components between the gate drivers and their respective MOSFET gates before actually implementing such measures. Doing so may interfere with the shoot-through protection.

### Output Voltage Selection

The output voltage can be programmed to any level between  $V_{IN}$  and the supplied external reference. An external resistor divider is used to scale the output voltage relative to the reference voltage and feed it back to the inverting input of the error amplifier, see Figure 2. However, since the value of  $R_1$  affects the values of the rest of the compensation components, it is advisable to keep its value less than  $5k\Omega$ .  $R_4$  can be calculated based on Equation 3:

$$R_4 = \frac{R_1 \times V_{REF}}{V_{OUT1} - V_{REF}} \quad (EQ. 3)$$

If the output voltage desired is  $V_{REF}$ , simply route the output back to the FB pin through  $R_1$ , but do not populate  $R_4$ .

FIGURE 2. OUTPUT VOLTAGE SELECTION

### Overcurrent Protection

The overcurrent function protects the converter from a shorted output by using the upper MOSFET ON-resistance,  $r_{DS(ON)}$ , to monitor the current. This method enhances the converter's efficiency and reduces cost by eliminating a current sensing resistor.

The overcurrent function cycles the soft-start function in a hiccup mode to provide fault protection. A resistor ( $R_{OCSET}$ ) programs the overcurrent trip level (see Typical Application diagrams on page 3 and page 4). An internal  $20\mu A$  (typical) current sink develops a voltage across  $R_{OCSET}$  that is referenced to  $V_{IN}$ . When the voltage across the upper MOSFET (also referenced to  $V_{IN}$ ) exceeds the voltage across  $R_{OCSET}$ , the overcurrent function initiates a soft-start sequence.

Figure 3 illustrates the protection feature responding to an overcurrent event. At time  $t_0$ , an overcurrent condition is sensed across the upper MOSFET. As a result, the regulator

is quickly shutdown and the internal soft-start function begins producing soft-start ramps. The delay interval seen by the output is equivalent to three soft-start cycles. The fourth internal soft-start cycle initiates a normal soft-start ramp of the output, at time  $t_1$ . The output is brought back into regulation by time  $t_2$ , as long as the overcurrent event has cleared.

FIGURE 3. OVERCURRENT PROTECTION RESPONSE

Had the cause of the overcurrent still been present after the delay interval, the overcurrent condition would be sensed and the regulator would be shut down again for another delay interval of three soft-start cycles. The resulting hiccup mode style of protection would continue to repeat indefinitely.

The overcurrent function will trip at a peak inductor current ( $I_{PEAK}$ ) determined by Equation 4:

$$I_{PEAK} = \frac{I_{OCSET} \times R_{OCSET}}{r_{DS(ON)}} \quad (EQ. 4)$$

where  $I_{OCSET}$  is the internal OCSET current source ( $20\mu A$  typical). The OC trip point varies mainly due to the MOSFET  $r_{DS(ON)}$  variations. To avoid overcurrent tripping in the normal operating load range, find the  $R_{OCSET}$  resistor from the Equation 4 with:

1. The maximum  $r_{DS(ON)}$  at the highest junction temperature.
2. The minimum  $I_{OCSET}$  from the "Specification Table" on page 7.
3. Determine  $I_{PEAK}$  for  $I_{PEAK} > I_{OUT(MAX)} + \frac{(\Delta I)}{2}$ , where  $\Delta I$  is the output inductor ripple current.

For an equation for the ripple current see the section under component guidelines titled “Output Inductor Selection” on page 11.

A small ceramic capacitor should be placed in parallel with  $R_{OCSET}$  to smooth the voltage across  $R_{OCSET}$  in the presence of switching noise on the input voltage.

### **Current Sinking**

The ISL6527, ISL6527A incorporate a MOSFET shoot-through protection method, which allows a converter to sink current as well as source current. Care should be exercised when designing a converter with the ISL6527, ISL6527A when it is known that the converter may sink current.

When the converter is sinking current, it is behaving as a boost converter that is regulating its input voltage. This means that the converter is boosting current into the input rail of the regulator. If there is nowhere for this current to go, such as to other distributed loads on the rail or through a voltage limiting protection device, the capacitance on this rail will absorb the current. This situation will allow the voltage level of the input rail to increase. If the voltage level of the rail is boosted to a level that exceeds the maximum voltage rating of any components attached to the input rail, then those components may experience an irreversible failure or experience stress that may shorten their lifespan. Ensuring that there is a path for the current to flow other than the capacitance on the rail will prevent this failure mode.

### **External Reference**

The ISL6527, ISL6527A allow the designer to determine the reference voltage that is used. This allows the ISL6527, ISL6527A to be used in many specialized applications, such as the  $V_{TT}$  termination voltage in a DDR Memory power supply, which must track the  $V_{DDQ}$  voltage by 50%. Care must be taken to insure that this voltage does not exceed 1.5V.

## **Application Guidelines**

### **Layout Considerations**

Layout is very important in high frequency switching converter design. With power devices switching efficiently at 300kHz or 600kHz, the resulting current transitions from one device to another cause voltage spikes across the interconnecting impedances and parasitic circuit elements. These voltage spikes can degrade efficiency, radiate noise into the circuit, and lead to device over-voltage stress. Careful component layout and printed circuit board design minimizes the voltage spikes in the converters.

As an example, consider the turn-off transition of the PWM MOSFET. Prior to turn-off, the MOSFET is carrying the full load current. During turn-off, current stops flowing in the MOSFET and is picked up by the lower MOSFET. Any parasitic inductance in the switched current path generates

a large voltage spike during the switching interval. Careful component selection, tight layout of the critical components, and short, wide traces minimizes the magnitude of voltage spikes.

There are two sets of critical components in a DC/DC converter using the ISL6527, ISL6527A. The switching components are the most critical because they switch large amounts of energy, and therefore tend to generate large amounts of noise. Next, are the small signal components, which connect to sensitive nodes or supply critical bypass current and signal coupling.

A multi-layer printed circuit board is recommended. Figure 4 shows the connections of the critical components in the converter. Note that capacitors  $C_{IN}$  and  $C_{OUT}$  could each represent numerous physical capacitors. Dedicate one solid layer, usually a middle layer of the PC board, for a ground plane and make all critical component ground connections with vias to this layer. Dedicate another solid layer as a power plane and break this plane into smaller islands of common voltage levels. Keep the metal runs from the PHASE terminals to the output inductor short. The power plane should support the input power and output power nodes. Use copper filled polygons on the top and bottom circuit layers for the phase nodes. Use the remaining printed circuit layers for small signal wiring. The wiring traces from the GATE pins to the MOSFET gates should be kept short and wide enough to easily handle the 1A of drive current.

The switching components should be placed close to the ISL6527, ISL6527A first. Minimize the length of the connections between the input capacitors,  $C_{IN}$ , and the power switches by placing them nearby. Position both the ceramic and bulk input capacitors as close to the upper MOSFET drain as possible. Position the output inductor and output capacitors between the upper MOSFET and lower MOSFET and the load.

The critical small signal components include any bypass capacitors, feedback components, and compensation components. Position the bypass capacitor,  $C_{BP}$ , close to the VCC pin with a via directly to the ground plane. Place the PWM converter compensation components close to the FB and COMP pins. The feedback resistors for both regulators should also be located as close as possible to the relevant FB pin with vias tied straight to the ground plane as required.

### **Feedback Compensation**

Figure 5 highlights the voltage-mode control loop for a synchronous-rectified buck converter. The output voltage ( $V_{OUT}$ ) is regulated to the Reference voltage level. The error amplifier (Error Amp) output ( $V_{E/A}$ ) is compared with the oscillator (OSC) triangular wave to provide a pulse-width modulated (PWM) wave with an amplitude of  $V_{IN}$  at the PHASE node. The PWM wave is smoothed by the output filter ( $L_O$  and  $C_O$ ).

error amplifier gain bounds the compensation gain. Check the compensation gain at  $F_{P2}$  with the capabilities of the error amplifier. The closed loop gain is constructed on the graph of Figure 6 by adding the modulator gain (in dB) to the compensation gain (in dB). This is equivalent to multiplying the modulator transfer function to the compensation transfer function and plotting the gain.

The compensation gain uses external impedance networks  $Z_{FB}$  and  $Z_{IN}$  to provide a stable, high bandwidth (BW) overall loop. A stable control loop has a gain crossing with  $-20\text{dB/decade}$  slope and a phase margin greater than  $45^\circ$ . Include worst-case component variations when determining phase margin.

FIGURE 6. ASYMPTOTIC BODE PLOT OF CONVERTER GAIN

### Component Selection Guidelines

#### Charge Pump Capacitor Selection

A capacitor across pins CT1 and CT2 is required to create the proper bias voltage for the ISL6527, ISL6527A when operating the IC from 3.3V. Selecting the proper capacitance value is important so that the bias current draw and the current required by the MOSFET gates do not overburden the capacitor. A conservative approach is presented in Equation 11:

$$C_{PUMP} = \frac{I_{BiasAndGate}}{V_{CC} \times f_s} \times 1.5 \quad \text{(EQ. 11)}$$

#### Output Capacitor Selection

An output capacitor is required to filter the output and supply the load transient current. The filtering requirements are a function of the switching frequency and the ripple current. The load transient requirements are a function of the slew rate ( $di/dt$ ) and the magnitude of the transient load current. These requirements are generally met with a mix of capacitors and careful layout.

Modern digital ICs can produce high transient load slew rates. High frequency capacitors initially supply the transient and slow the current load rate seen by the bulk capacitors. The bulk filter capacitor values are generally determined by

the ESR (Effective Series Resistance) and voltage rating requirements rather than actual capacitance requirements.

High frequency decoupling capacitors should be placed as close to the power pins of the load as physically possible. Be careful not to add inductance in the circuit board wiring that could cancel the usefulness of these low inductance components. Consult with the manufacturer of the load on specific decoupling requirements.

Use only specialized low-ESR capacitors intended for switching-regulator applications for the bulk capacitors. The bulk capacitor's ESR will determine the output ripple voltage and the initial voltage drop after a high slew-rate transient. An aluminum electrolytic capacitor's ESR value is related to the case size with lower ESR available in larger case sizes. However, the Equivalent Series Inductance (ESL) of these capacitors increases with case size and can reduce the usefulness of the capacitor to high slew-rate transient loading. Unfortunately, ESL is not a specified parameter. Work with your capacitor supplier and measure the capacitor's impedance with frequency to select a suitable component. In most cases, multiple electrolytic capacitors of small case size perform better than a single large case capacitor.

#### Output Inductor Selection

The output inductor is selected to meet the output voltage ripple requirements and minimize the converter's response time to the load transient. The inductor value determines the converter's ripple current and the ripple voltage is a function of the ripple current. The ripple voltage and current are approximated by Equations 12 and 13:

$$\Delta I = \frac{V_{IN} - V_{OUT}}{f_s \times L} \times \frac{V_{OUT}}{V_{IN}} \quad \text{(EQ. 12)}$$

$$\Delta V_{OUT} = \Delta I \times ESR \quad \text{(EQ. 13)}$$

Increasing the value of inductance reduces the ripple current and voltage. However, the large inductance values reduce the converter's response time to a load transient.

One of the parameters limiting the converter's response to a load transient is the time required to change the inductor current. Given a sufficiently fast control loop design, the ISL6527, ISL6527A will provide either 0% or 100% duty cycle in response to a load transient. The response time is the time required to slew the inductor current from an initial current value to the transient current level. During this interval the difference between the inductor current and the transient current level must be supplied by the output capacitor. Minimizing the response time can minimize the output capacitance required.

The response time to a transient is different for the application of load and the removal of load. Equations 14 and 15 give the

approximate response time interval for application and removal of a transient load:

$$t_{\text{RISE}} = \frac{L \times I_{\text{TRAN}}}{V_{\text{IN}} - V_{\text{OUT}}} \quad (\text{EQ. 14})$$

$$t_{\text{FALL}} = \frac{L \times I_{\text{TRAN}}}{V_{\text{OUT}}} \quad (\text{EQ. 15})$$

where:  $I_{\text{TRAN}}$  is the transient load current step,  $t_{\text{RISE}}$  is the response time to the application of load, and  $t_{\text{FALL}}$  is the response time to the removal of load. The worst case response time can be either at the application or removal of load. Be sure to check both Equations 14 and 15 at the minimum and maximum output levels for the worst case response time.

### Input Capacitor Selection

Use a mix of input bypass capacitors to control the voltage overshoot across the MOSFETs. Use small ceramic capacitors for high frequency decoupling and bulk capacitors to supply the current needed each time  $Q_1$  turns on. Place the small ceramic capacitors physically close to the MOSFETs and between the drain of  $Q_1$  and the source of  $Q_2$ .

The important parameters for the bulk input capacitor are the voltage rating and the RMS current rating. For reliable operation, select the bulk capacitor with voltage and current ratings above the maximum input voltage and largest RMS current required by the circuit. The capacitor voltage rating should be at least 1.25x greater than the maximum input voltage and a voltage rating of 1.5x is a conservative guideline. The RMS current rating requirement for the input capacitor of a buck regulator is approximately 1/2 the DC load current.

The maximum RMS current required by the regulator may be closely approximated through Equation 16:

$$I_{\text{RMS MAX}} = \sqrt{\frac{V_{\text{OUT}}}{V_{\text{IN}}} \times \left( I_{\text{OUT MAX}}^2 + \frac{1}{12} \times \left( \frac{V_{\text{IN}} - V_{\text{OUT}}}{L \times f_s} \times \frac{V_{\text{OUT}}}{V_{\text{IN}}} \right)^2 \right)} \quad (\text{EQ. 16})$$

For a through-hole design, several electrolytic capacitors may be needed. For surface mount designs, solid tantalum capacitors can be used, but caution must be exercised with regard to the capacitor surge current rating. These capacitors must be capable of handling the surge-current at power-up. Some capacitor series available from reputable manufacturers are surge current tested.

### MOSFET Selection/Considerations

The ISL6527, ISL6527A require two N-Channel power MOSFETs. These should be selected based upon  $r_{\text{DS(ON)}}$ , gate supply requirements, and thermal management requirements.

In high-current applications, the MOSFET power dissipation, package selection and heatsink are the dominant design factors. The power dissipation includes two loss components; conduction loss and switching loss. The conduction losses are the largest component of power dissipation for both the upper and the lower MOSFETs. These losses are distributed between

the two MOSFETs according to duty factor. The switching losses seen when sourcing current will be different from the switching losses seen when sinking current. When sourcing current, the upper MOSFET realizes most of the switching losses. The lower switch realizes most of the switching losses when the converter is sinking current (see Equations 17 and 18). These equations assume linear voltage-current transitions and do not adequately model power loss due the reverse-recovery of the upper and lower MOSFET's body diode. The gate-charge losses are dissipated by the ISL6527, ISL6527A and don't heat the MOSFETs. However, large gate-charge increases the switching interval,  $t_{\text{SW}}$  which increases the MOSFET switching losses. Ensure that both MOSFETs are within their maximum junction temperature at high ambient temperature by calculating the temperature rise according to package thermal-resistance specifications. A separate heatsink may be necessary depending upon MOSFET power, package type, ambient temperature and air flow.

#### Losses while Sourcing current

$$P_{\text{UPPER}} = I_o^2 \times r_{\text{DS(ON)}} \times D + \frac{1}{2} \cdot I_o \times V_{\text{IN}} \times t_{\text{SW}} \times f_s$$

$$P_{\text{LOWER}} = I_o^2 \times r_{\text{DS(ON)}} \times (1 - D) \quad (\text{EQ. 17})$$

#### Losses while Sinking current

$$P_{\text{UPPER}} = I_o^2 \times r_{\text{DS(ON)}} \times D$$

$$P_{\text{LOWER}} = I_o^2 \times r_{\text{DS(ON)}} \times (1 - D) + \frac{1}{2} \cdot I_o \times V_{\text{IN}} \times t_{\text{SW}} \times f_s \quad (\text{EQ. 18})$$

where:  $D$  is the duty cycle =  $V_{\text{OUT}}/V_{\text{IN}}$ ,  $t_{\text{SW}}$  is the combined switch ON- and OFF-time, and  $f_s$  is the switching frequency.

Given the reduced available gate bias voltage (5V), logic-level or sub-logic-level transistors should be used for both N-MOSFETs. Caution should be exercised with devices exhibiting very low  $V_{\text{GS(ON)}}$  characteristics. The shoot-through protection present aboard the ISL6527, ISL6527A may be circumvented by these MOSFETs if they have large parasitic impedances and/or capacitances that would inhibit the gate of the MOSFET from being discharged below its threshold level before the complementary MOSFET is turned on.

### Bootstrap Component Selection

External bootstrap components, a diode and capacitor, are required to provide sufficient gate enhancement to the upper MOSFET. The internal MOSFET gate driver is supplied by the external bootstrap circuitry as shown in Figure 7. The boot capacitor,  $C_{\text{BOOT}}$ , develops a floating supply voltage referenced to the PHASE pin. This supply is refreshed each cycle, when  $D_{\text{BOOT}}$  conducts, to a voltage of  $CPV_{\text{OUT}}$  less the boot diode drop,  $V_D$ , plus the voltage rise across  $Q_{\text{LOWER}}$ .

Just after the PWM switching cycle begins and the charge transfer from the bootstrap capacitor to the gate capacitance is complete, the voltage on the bootstrap capacitor is at its lowest point during the switching cycle. The charge lost on the bootstrap capacitor will be equal to the charge transferred to

FIGURE 7. UPPER GATE DRIVE BOOTSTRAP

the equivalent gate-source capacitance of the upper MOSFET as shown in Equation 19:

$$Q_{GATE} = C_{BOOT} \times (V_{BOOT1} - V_{BOOT2}) \quad (\text{EQ. 19})$$

where  $Q_{GATE}$  is the maximum total gate charge of the upper MOSFET,  $C_{BOOT}$  is the bootstrap capacitance,  $V_{BOOT1}$  is the bootstrap voltage immediately before turn-on, and  $V_{BOOT2}$  is the bootstrap voltage immediately after turn-on.

The bootstrap capacitor begins its refresh cycle when the gate drive begins to turn-off the upper MOSFET. A refresh cycle ends when the upper MOSFET is turned on again, which varies depending on the switching frequency and duty cycle.

The minimum bootstrap capacitance can be calculated by rearranging Equation 19 and solving for  $C_{BOOT}$  in Equation 20.

$$C_{BOOT} \geq \frac{Q_{GATE}}{V_{BOOT1} - V_{BOOT2}} \quad (\text{EQ. 20})$$

Typical gate charge values for MOSFETs considered in these types of applications range from 20 to 100nC. Since the voltage drop across  $Q_{LOWER}$  is negligible,  $V_{BOOT1}$  is simply  $V_{CPVOUT} - V_D$ . A schottky diode is recommended to minimize the voltage drop across the bootstrap capacitor during the on-time of the upper MOSFET. Initial calculations with  $V_{BOOT2}$  no less than 4V will quickly help narrow the bootstrap capacitor range.

For example, consider an upper MOSFET is chosen with a maximum gate charge,  $Q_g$ , of 100nC. Limiting the voltage drop across the bootstrap capacitor to 1V results in a value of no less than 0.1 $\mu$ F. The tolerance of the ceramic capacitor should also be considered when selecting the final bootstrap capacitance value.

A fast recovery diode is recommended when selecting a bootstrap diode to reduce the impact of reverse recovery charge loss. Otherwise, the recovery charge,  $Q_{RR}$ , would have to be added to the gate charge of the MOSFET and taken into

consideration when calculating the minimum bootstrap capacitance.

### ISL6527, ISL6527A DC/DC Converter Application Circuit

Figure 8 shows an application circuit of a DC/DC Converter. Detailed information on the circuit, including a complete Bill-of-Materials and circuit board description, can be found in Application Note AN1021.

<http://www.intersil.com/data/an/an1021.pdf>

Component Selection Notes:

- C3, C8, C9 - Each 150mF, Panasonic EEF-UE0J151R or Equivalent.
- D1 - 30mA Schottky Diode, MA732 or Equivalent
- L1 - 1μH Inductor, Panasonic P/N ETQ-P6F1ROSFA or Equivalent.
- Q1 - Fairchild MOSFET; ITF86110DK8.

## Revision History

The revision history provided is for informational purposes only and is believed to be accurate, but not warranted. Please go to the web to make sure that you have the latest revision.

DATE	REVISION	CHANGE
September 29, 2015	FN9056.11	Updated Ordering Information Table on page 2. Added Revision History and About Intersil sections. Updated POD M14.15 from rev 0 to rev 1. Changes since rev 0: Added land pattern and moved dimensions from table onto drawing

## About Intersil

Intersil Corporation is a leading provider of innovative power management and precision analog solutions. The company's products address some of the largest markets within the industrial and infrastructure, mobile computing and high-end consumer markets.

For the most updated datasheet, application notes, related documentation and related parts, please see the respective product information page found at [www.intersil.com](http://www.intersil.com).

You may report errors or suggestions for improving this datasheet by visiting [www.intersil.com/ask](http://www.intersil.com/ask).

Reliability reports are also available from our website at [www.intersil.com/support](http://www.intersil.com/support)

© Copyright Intersil Americas LLC 2002-2015. All Rights Reserved.  
All trademarks and registered trademarks are the property of their respective owners.

For additional products, see [www.intersil.com/en/products.html](http://www.intersil.com/en/products.html)

Intersil products are manufactured, assembled and tested utilizing ISO9001 quality systems as noted in the quality certifications found at [www.intersil.com/en/support/qualandreliability.html](http://www.intersil.com/en/support/qualandreliability.html)

*Intersil products are sold by description only. Intersil may modify the circuit design and/or specifications of products at any time without notice, provided that such modification does not, in Intersil's sole judgment, affect the form, fit or function of the product. Accordingly, the reader is cautioned to verify that datasheets are current before placing orders. Information furnished by Intersil is believed to be accurate and reliable. However, no responsibility is assumed by Intersil or its subsidiaries for its use; nor for any infringements of patents or other rights of third parties which may result from its use. No license is granted by implication or otherwise under any patent or patent rights of Intersil or its subsidiaries.*

# Package Outline Drawing

## L16.5x5B

16 LEAD QUAD FLAT NO-LEAD PLASTIC PACKAGE

Rev 2, 02/08

NOTES:

1. Dimensions are in millimeters.  
Dimensions in ( ) for Reference Only.
2. Dimensioning and tolerancing conform to AMSE Y14.5m-1994.
3. Unless otherwise specified, tolerance : Decimal  $\pm 0.05$
4. Dimension b applies to the metallized terminal and is measured between 0.15mm and 0.30mm from the terminal tip.
5. Tiebar shown (if present) is a non-functional feature.
6. The configuration of the pin #1 identifier is optional, but must be located within the zone indicated. The pin #1 identifier may be either a mold or mark feature.

# Package Outline Drawing

## M14.15

### 14 LEAD NARROW BODY SMALL OUTLINE PLASTIC PACKAGE

Rev 1, 10/09

**NOTES:**

1. Dimensions are in millimeters.  
Dimensions in ( ) for Reference Only.
2. Dimensioning and tolerancing conform to AMSEY14.5m-1994.
3. Datums A and B to be determined at Datum H.
4. Dimension does not include interlead flash or protrusions.  
Interlead flash or protrusions shall not exceed 0.25mm per side.
5. The pin #1 identifier may be either a mold or mark feature.
6. Does not include dambar protrusion. Allowable dambar protrusion shall be 0.10mm total in excess of lead width at maximum condition.
7. Reference to JEDEC MS-012-AB.

## Данный компонент на территории Российской Федерации

### Вы можете приобрести в компании MosChip.

Для оперативного оформления запроса Вам необходимо перейти по данной ссылке:

<http://moschip.ru/get-element>

Вы можете разместить у нас заказ для любого Вашего проекта, будь то серийное производство или разработка единичного прибора.

В нашем ассортименте представлены ведущие мировые производители активных и пассивных электронных компонентов.

Нашей специализацией является поставка электронной компонентной базы двойного назначения, продукции таких производителей как XILINX, Intel (ex.ALTERA), Vicor, Microchip, Texas Instruments, Analog Devices, Mini-Circuits, Amphenol, Glenair.

Сотрудничество с глобальными дистрибьюторами электронных компонентов, предоставляет возможность заказывать и получать с международных складов практически любой перечень компонентов в оптимальные для Вас сроки.

На всех этапах разработки и производства наши партнеры могут получить квалифицированную поддержку опытных инженеров.

Система менеджмента качества компании отвечает требованиям в соответствии с ГОСТ Р ИСО 9001, ГОСТ РВ 0015-002 и ЭС РД 009
