## Isolated Amplifier for Current Shunt Measurement

The Si8920 is a galvanically isolated analog amplifier. The low-voltage differential input is ideal for measuring voltage across a current shunt resistor or for any place where a sensor must be isolated from the control system. The output is a differential analog signal amplified by either 8.1x or 16.2x.

The very low signal delay of the Si8920 allows control systems to respond quickly to fault conditions or changes in load. Low offset and gain drift ensure that accuracy is maintained over the entire operating temperature range. Exceptionally high common-mode transient immunity means that the Si8920 delivers accurate measurements even in the presence of high-power switching as is found in motor drive systems and inverters.

The Si8920 isolated amplifier utilizes Silicon Labs' proprietary isolation technology. It supports up to 5.0 kVrms withstand voltage per UL1577. This technology enables higher performance, reduced variation with temperature and age, tighter part-to-part matching, and longer lifetimes compared to other isolation technologies.

Automotive Grade is available for certain part numbers. These products are built using automotive-specific flows at all steps in the manufacturing process to ensure the robustness and low defectivity required for automotive applications.

## 2. System Overview

The input to the Si8920 is designed for low-voltage, differential signals. This is ideal for connection to low resistance current shunt measurement resistors. The Si8920A has a full scale input range of  $\pm 100$  mV, and the Si8920B has a full scale input range of  $\pm 200$  mV. In both cases, the internal gain is set so that the full scale output is 1.6 V.

The Si8920 modulates the analog signal in a unique way for transmission across the semiconductor based isolation barrier. The input signal is first converted to a pulse-width modulated digital signal. For transmission across the isolation barrier, the signal is further modulated with a high frequency carrier. On the other side of the isolation barrier, the signal is demodulated and the carrier portion is removed. The resulting PWM signal is then used to faithfully reproduce the analog signal. This solution provides exceptional signal bandwidth and accuracy.

Pins 1–8 (1–4 DIP8) are shorted together to form the first terminal, and pins 9–16 (5–8 DIP8) are shorted together to form the second terminal. The parameters are then measured between these two terminals.
