ANALOG DEVICES

Ultralow Distortion, Wide Bandwidth Voltage Feedback Op Amps

AD9631/AD9632

FEATURES
Wide Bandwidth
  AD9631, G = +1
  AD9632, G = +2
  Small Signal
    320 MHz
    250 MHz
  Large Signal (4 V p-p)
    175 MHz
    180 MHz
Ultralow Distortion (SFDR), Low Noise
  –113 dBc Typ @ 1 MHz
  –95 dBc Typ @ 5 MHz
  –72 dBc Typ @ 20 MHz
  46 dBm Third Order Intercept @ 25 MHz
  7.0 nV/√Hz Spectral Noise Density
High Speed
  Slew Rate 1300 V/μs
  Settling 16 ns to 0.01%, 2 V Step
  ±3 V to ±5 V Supply Operation
  17 mA Supply Current

APPLICATIONS
ADC Input Driver
Differential Amplifiers
IF/RF Amplifiers
Pulse Amplifiers
Professional Video
DAC Current to Voltage
Baseband and Video Communications
Pin Diode Receivers
Active Filters/Integrators/Log Amps

PIN CONFIGURATION
8-Lead PDIP (N)
and SOIC (R) Packages

NC = NO CONNECT

A proprietary design architecture has produced an amplifier that combines many of the best characteristics of both current feedback and voltage feedback amplifiers. The AD9631 and AD9632 exhibit exceptionally fast and accurate pulse response (16 ns to 0.01%) as well as extremely wide small signal and large signal bandwidth and ultralow distortion. The AD9631 achieves –72 dBc at 20 MHz, and 320 MHz small signal and 175 MHz large signal bandwidths.

These characteristics position the AD9631/AD9632 ideally for driving flash as well as high resolution ADCs. Additionally, the balanced high impedance inputs of the voltage feedback architecture allow maximum flexibility when designing active filters.

The AD9631/AD9632 are offered in the industrial (–40°C to +85°C) temperature range. They are available in PDIP and SOIC.
GENERAL DESCRIPTION
The AD9631 and AD9632 are very high speed and wide bandwidth amplifiers. They are an improved performance alternative to the AD9621 and AD9622. The AD9631 is unity gain stable. The AD9632 is stable at gains of 2 or greater. Using a voltage feedback architecture, the AD9631/AD9632's exceptional settling time, bandwidth, and low distortion meet the requirements of many applications that previously depended on current feedback amplifiers. Its classical op amp structure works much more predictably in many designs.

AD9631

AD9632
MAXIMUM POWER DISSIPATION

The maximum power that can be safely dissipated by these
devices is limited by the associated rise in junction temperature.
The maximum safe junction temperature for plastic encapsulated
devices is determined by the glass transition temperature of the
plastic, approximately 150°C. Exceeding this limit temporarily
may cause a shift in parametric performance due to a change in
the stresses exerted on the die by the package. Exceeding a junc-
tion temperature of 175°C for an extended period can result in
device failure.

While the AD9631 and AD9632 are internally short circuit
protected, this may not be sufficient to guarantee that the maxi-
mum junction temperature (150°C) is not exceeded under all
conditions. To ensure proper operation, it is necessary to observe
the maximum power derating curves.
Figure 2. Maximum Power Dissipation

THEORY OF OPERATION

General

The AD9631 and AD9632 are wide bandwidth, voltage feedback amplifiers. Since their open-loop frequency response follows the conventional 6 dB/octave roll-off, their gain bandwidth product is basically constant. Increasing their closed-loop gain results in a corresponding decrease in small signal bandwidth. This can be observed by noting the bandwidth specification between the AD9631 (gain of +1) and AD9632 (gain of +2). The AD9631/AD9632 typically maintain 65 degrees of phase margin. This high margin minimizes the effects of signal and noise peaking.

Feedback Resistor Choice

The value of the feedback resistor is critical for optimum performance on the AD9631 (gain of +1) and less critical as the gain increases. Therefore, this section is specifically targeted at the AD9631.

At minimum stable gain (+1), the AD9631 provides optimum dynamic performance with R_F = 140 Ω. This resistor acts as a parasitic suppressor only against damped RF oscillations that can occur due to lead (input, feedback) inductance and parasitic capacitance. This value of R_F provides the best combination of wide bandwidth, low parasitic peaking, and fast settling time.

In fact, for the same reasons, a 100 Ω–130 Ω resistor should be placed in series with the positive input for other AD9631 noninverting and all AD9631 inverting configurations. The correct connection is shown in Figures 3 and 4.
Figure 3. Noninverting Operation
Figure 4. Inverting Operation

When the AD9631 is used in the transimpedance (I to V) mode, such as in photodiode detection, the value of R_F and diode capacitance (C_I) are usually known. Generally, the value of R_F selected will be in the kΩ range, and a shunt capacitor (C_F) across R_F will be required to maintain good amplifier stability. The value of C_F required to maintain optimal flatness (<1 dB peaking) and settling time can be estimated as

$$C_F \cong \left[\left(2\omega_O C_I R_F - 1 \right) / \omega_O{}^2 R_F{}^2 \right]^{\frac{1}{2}}$$

where ω_O is equal to the unity gain bandwidth product of the amplifier in rad/sec, and C_I is the equivalent total input capacitance at the inverting input. Typically $\omega_O = 800 \times 10^6$ rad/sec (see TPC 15).

As an example, choosing R_F = 10 kΩ and C_I = 5 pF requires C_F to be 1.1 pF (Note: C_I includes both source and parasitic circuit capacitance). The bandwidth of the amplifier can be estimated using the C_F calculated as

$$f_{3dB} \cong \frac{1.6}{2\pi R_F C_F}$$
Figure 5. Transimpedance Configuration

For general voltage gain applications, the amplifier bandwidth can be closely estimated as

$$f_{3dB} \cong \frac{\omega_O}{2\pi \left(1 + R_F/R_G \right)}$$

This estimation loses accuracy for gains of +2/–1 or lower due to the amplifier's damping factor. For these "low gain" cases, the bandwidth will actually extend beyond the calculated value (see TPCs 13 and 25).

As a general rule, capacitor C_F will not be required if

$$\left(R_F \| R_G \right) \times C_I \leq \frac{NG}{4\,\omega_O}$$

where NG is the noise gain ($1 + R_F/R_G$) of the circuit. For most voltage gain applications, this should be the case.

AD9631/AD9632

Pulse Response

Unlike a traditional voltage feedback amplifier, where the slew speed is dictated by its front end dc quiescent current and gain bandwidth product, the AD9631 and AD9632 provide "on-demand" current that increases proportionally to the input "step" signal amplitude. This results in slew rates (1300 V/μs) comparable to wideband current feedback designs. This, combined with relatively low input noise current (2.0 pA/$\sqrt{Hz}$), gives the AD9631 and AD9632 the best attributes of both voltage and current feedback amplifiers.

Large Signal Performance

The outstanding large signal operation of the AD9631 and AD9632 is due to a unique, proprietary design architecture. In order to maintain this level of performance, the maximum 550 V-MHz product must be observed (e.g., @ 100 MHz, $V_O \le 5.5$ V p-p).

Power Supply Bypassing

Adequate power supply bypassing can be critical when optimizing the performance of a high frequency circuit. Inductance in the power supply leads can form resonant circuits that produce peaking in the amplifier's response. In addition, if large current transients must be delivered to the load, then bypass capacitors (typically greater than 1 μF) will be required to provide the best settling time and lowest distortion. A parallel combination of at least 4.7 μF, and between 0.1 μF and 0.01 μF, is recommended. Some brands of electrolytic capacitors will require a small series damping resistor ≈4.7 Ω for optimum results.

Driving Capacitive Loads

The AD9631 and AD9632 were designed primarily to drive nonreactive loads. If driving loads with a capacitive component is desired, the best frequency response is obtained by the addition of a small series resistance as shown in Figure 6. The accompanying graph shows the optimum value for R_{SERIES} versus capacitive load. It is worth noting that the frequency response of the circuit when driving large capacitive loads will be dominated by the passive roll-off of R_{SERIES} and C_L.
Figure 6. Driving Capacitive Loads
Figure 7. Recommended R_{SERIES} vs. Capacitive Load

APPLICATIONS

The AD9631 and AD9632 are voltage feedback amplifiers well suited for applications such as photodetectors, active filters, and log amplifiers. The devices' wide bandwidth (320 MHz), phase margin (65°), low current noise (2.0 pA/$\sqrt{Hz}$), and slew rate (1300 V/μs) give higher performance capabilities to these applications over previous voltage feedback designs.

With a settling time of 16 ns to 0.01% and 11 ns to 0.1%, the devices are an excellent choice for DAC I/V conversion. The same characteristics along with low harmonic distortion make them a good choice for ADC buffering/amplification. With superb linearity at relatively high signal frequencies, the AD9631 and AD9632 are ideal drivers for ADCs up to 12 bits.

Operation as a Video Line Driver

The AD9631 and AD9632 have been designed to offer outstanding performance as video line drivers. The important specifications of differential gain (0.02%) and differential phase (0.02°) meet the most exacting HDTV demands for driving video loads.

Figure 8. Video Line Driver

Active Filters

The wide bandwidth and low distortion of the AD9631 and AD9632 are ideal for the realization of higher bandwidth active filters. These characteristics, while being more common in many current feedback op amps, are offered in the AD9631 and AD9632 in a voltage feedback configuration. Many active filter configurations are not realizable with current feedback amplifiers.

A multiple feedback active filter requires a voltage feedback amplifier and is more demanding of op amp performance than other active filter configurations, such as the Sallen-Key. In general, the amplifier should have a bandwidth that is at least 10 times the bandwidth of the filter if problems due to phase shift of the amplifier are to be avoided.

Figure 9 is an example of a 20 MHz low-pass multiple feedback active filter using an AD9632.
Figure 9. Active Filter Circuit

Choose

F_O = Cutoff Frequency = 20 MHz

α = Damping Ratio = $1/Q = 2$

H = Absolute Value of Circuit Gain = $\left| \dfrac{-R4}{R1} \right| = 1$

Then

$$k = 2\pi F_O\, C1$$
$$C2 = \frac{4C1(H+1)}{\alpha^2}$$
$$R1 = \frac{\alpha}{2HK}$$
$$R3 = \frac{\alpha}{2K(H+1)}$$
$$R4 = H(R1)$$

A/D Converter Driver

As A/D converters move toward higher speeds with higher resolutions, there becomes a need for high performance drivers that will not degrade the analog signal to the converter. It is desirable from a system's standpoint that the A/D be the element in the signal chain that ultimately limits overall distortion. This places new demands on the amplifiers that are used to drive fast, high resolution A/Ds.

With high bandwidth, low distortion, and fast settling time, the AD9631 and AD9632 make high performance A/D drivers for advanced converters. Figure 10 is an example of an AD9631 used as an input driver for an AD872, a 12-bit, 10 MSPS A/D converter.
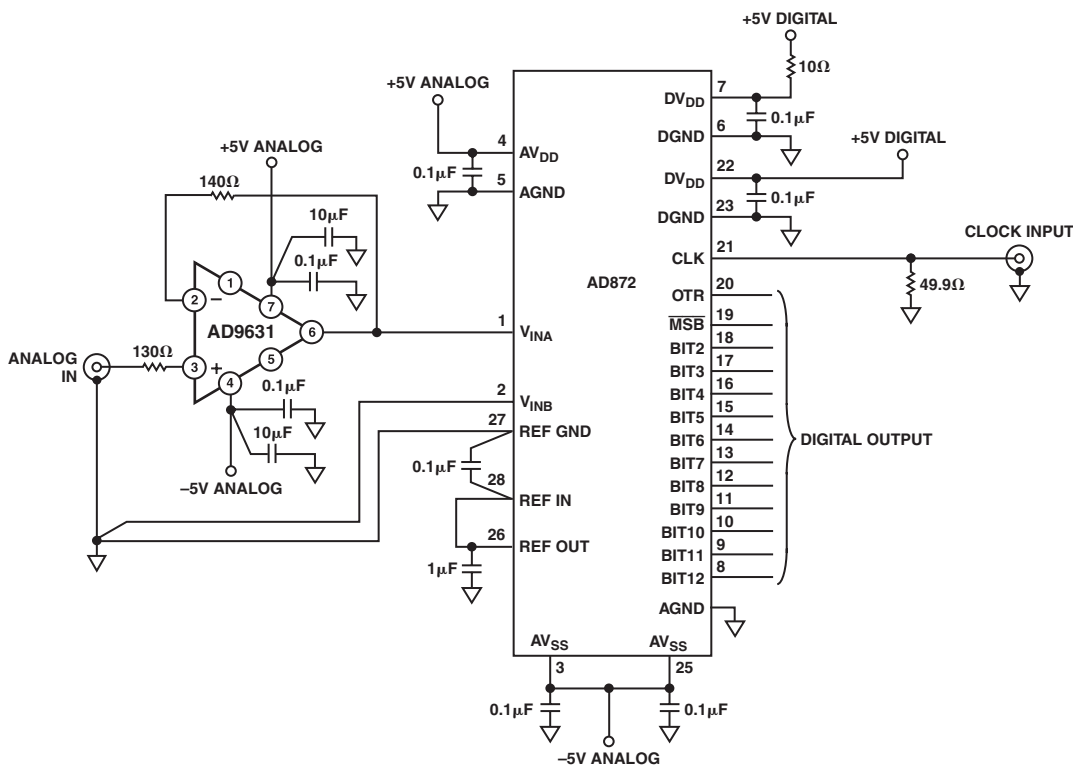

Figure 10. AD9631 Used as Driver for an AD872, a 12-Bit, 10 MSPS A/D Converter

AD9631/AD9632

Layout Considerations

The specified high speed performance of the AD9631 and AD9632 requires careful attention to board layout and component selection. Proper RF design techniques and low-pass parasitic component selection are mandatory.

The PCB should have a ground plane covering all unused portions of the component side of the board to provide a low impedance path. The ground plane should be removed from the area near the input pins to reduce stray capacitance.

Chip capacitors should be used for supply bypassing (see Figure 10). One end should be connected to the ground plane, and the other within 1/8 inch of each power pin. An additional large (0.47 μF–10 μF) tantalum electrolytic capacitor should be connected in parallel, though not necessarily so close, to supply current for fast, large signal changes at the output.

The feedback resistor should be located close to the inverting input pin in order to keep the stray capacitance at this node to a minimum. Capacitance variations of less than 1 pF at the inverting input will significantly affect high speed performance.

Stripline design techniques should be used for long signal traces (greater than about 1 inch). These should be designed with a characteristic impedance of 50 Ω or 75 Ω and be properly terminated at each end.

Вы можете приобрести в компании MosChip.

Для оперативного оформления запроса Вам необходимо перейти по данной ссылке:

http://moschip.ru/get-element

Вы можете разместить у нас заказ для любого Вашего проекта, будь то серийное   производство или разработка единичного прибора.

В нашем ассортименте представлены ведущие мировые производители активных и пассивных электронных компонентов.

Нашей специализацией является поставка электронной компонентной базы двойного назначения, продукции таких производителей как XILINX, Intel (ex.ALTERA), Vicor, Microchip, Texas Instruments, Analog Devices, Mini-Circuits, Amphenol, Glenair.

Сотрудничество с глобальными дистрибьюторами электронных компонентов, предоставляет возможность заказывать и получать с международных складов практически любой перечень компонентов в оптимальные для Вас сроки.

На всех этапах разработки и производства наши партнеры могут получить квалифицированную поддержку опытных инженеров.

Система менеджмента качества компании отвечает требованиям в соответствии с ГОСТ Р ИСО 9001, ГОСТ РВ 0015-002 и ЭС РД 009
