

2-Wire-Interfaced, 2.5V to 5.5V, 20-Port or 28-Port LED Display Driver and I/O Expander

General Description

The MAX6956 compact, serial-interfaced LED display driver/I/O expander provide microprocessors with up to 28 ports. Each port is individually user configurable to either a logic input, logic output, or common-anode (CA) LED constant-current segment driver. Each port configured as an LED segment driver behaves as a digitally controlled constant-current sink, with 16 equal current steps from 1.5mA to 24mA. The LED drivers are suitable for both discrete LEDs and CA numeric and alphanumeric LED digits.

Each port configured as a general-purpose I/O (GPIO) can be either a push-pull logic output capable of sinking 10mA and sourcing 4.5mA, or a Schmitt logic input with optional internal pullup. Seven ports feature configurable transition detection logic, which generates an interrupt upon change of port logic level. The MAX6956 is controlled through an I²C-compatible 2-wire serial interface, and uses four-level logic to allow 16 I²C addresses from only 2 select pins.

The MAX6956AAX and MAX6956ATL have 28 ports and are available in 36-pin SSOP and 40-pin thin QFN packages, respectively. The MAX6956AAI and MAX6956ANI have 20 ports and are available in 28-pin SSOP and 28-pin DIP packages, respectively.

For an SPI-interfaced version, refer to the MAX6957 data sheet. For a lower cost pin-compatible port expander without the constant-current LED drive capability, refer to the MAX7300 data sheet.

Applications

| | |
|---------------|------------------------|
| Set-Top Boxes | Bar Graph Displays |
| Panel Meters | Industrial Controllers |
| White Goods | System Monitoring |
| Automotive | |

Typical Operating Circuit appears at end of data sheet.

Features

- ◆ 400kbps I²C-Compatible Serial Interface
- ◆ 2.5V to 5.5V Operation
- ◆ -40°C to +125°C Temperature Range
- ◆ 20 or 28 I/O Ports, Each Configurable as
 - Constant-Current LED Driver
 - Push-Pull Logic Output
 - Schmitt Logic Input
 - Schmitt Logic Input with Internal Pullup
- ◆ 11µA (max) Shutdown Current
- ◆ 16-Step Individually Programmable Current Control for Each LED
- ◆ Logic Transition Detection for Seven I/O Ports

 Packages containing lead(Pb).....+240°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Detailed Description

The MAX6956 LED driver/GPIO peripheral provides up to 28 I/O ports, P4 to P31, controlled through an I²C-compatible serial interface. The ports can be configured to any combination of constant-current LED drivers, logic inputs and logic outputs, and default to logic inputs on power-up. When fully configured as an LED driver, the MAX6956 controls up to 28 LED segments with individual 16-step adjustment of the constant current through each LED segment. A single resistor sets the maximum segment current for all segments, with a maximum of 24mA per segment. The MAX6956 drives any combination of discrete LEDs and CA digits, including seven-segment and starburst alphanumeric types.

Figure 1 is the MAX6956 functional diagram. Any I/O port can be configured as a push-pull output (sinking 10mA, sourcing 4.5mA), or a Schmitt-trigger logic input. Each input has an individually selectable internal pullup resistor. Additionally, transition detection allows seven ports (P24 through P30) to be monitored in any maskable combination for changes in their logic status. A detected transition is flagged through a status register bit, as well as an interrupt pin (port P31), if desired.

The *Typical Operating Circuit* shows two MAX6956s working together controlling three monochrome 16-seg-

ment-plus-DP displays, with five ports left available for GPIO (P26–P31 of U2).

The port configuration registers set the 28 ports, P4 to P31, individually as either LED drivers or GPIO. A pair of bits in registers 0x09 through 0x0F sets each port's configuration (Tables 1 and 2).

The 36-pin MAX6956AAX has 28 ports, P4 to P31. The 28-pin MAX6956ANI and MAX6956AAI make only 20 ports available, P12 to P31. The eight unused ports should be configured as outputs on power-up by writing 0x55 to registers 0x09 and 0x0A. If this is not done, the eight unused ports remain as unconnected inputs and quiescent supply current rises, although there is no damage to the part.

Register Control of I/O Ports and LEDs Across Multiple Drivers

The MAX6956 offers 20 or 28 I/O ports, depending on package choice. These can be applied to a variety of combinations of different display types, for example: seven, 7-segment digits (Figure 7). This example requires two MAX6956s, with one digit being driven by both devices, half by one MAX6956, half by the other (digit 4 in this example). The two drivers are static, and therefore do not need to be synchronized. The MAX6956 sees CA digits as multiple discrete LEDs. To

Table 2. Port Configuration Matrix

| MODE | FUNCTION | PORT REGISTER (0x20–0x5F) | PIN BEHAVIOR | ADDRESS CODE (HEX) | PORT CONFIGURATION BIT PAIR | |
|--------|---------------------------|----------------------------------|--|--------------------|-----------------------------|-------|
| | | | | | UPPER | LOWER |
| Output | LED Segment Driver | Register bit = 0 | High impedance | 0x09 to 0x0F | 0 | 0 |
| | | Register bit = 1 | Open-drain current sink, with sink current (up to 24mA) determined by the appropriate current register | | | |
| Output | GPIO Output | Register bit = 0 | Active-low logic output | 0x09 to 0x0F | 0 | 1 |
| | | Register bit = 1 | Active-high logic output | | | |
| Input | GPIO Input Without Pullup | Register bit = input logic level | Schmitt logic input | 0x09 to 0x0F | 1 | 0 |
| Input | GPIO Input with Pullup | | Schmitt logic input with pullup | 0x09 to 0x0F | 1 | 1 |

Note: The logic is inverted between the two output modes; a high makes the output go low in LED segment driver mode (0x00) to turn that segment on; in GPIO output mode (0x01), a high makes the output go high.

simplify access to displays that overlap two MAX6956s, the MAX6956 provides four virtual ports, P0 through P3. To update an overlapping digit, send the same code twice as an eight-port write, once to P28 through P35 of the first driver, and again to P0 through P7 of the second driver. The first driver ignores the last 4 bits and the second driver ignores the first 4 bits.

Two addressing methods are available. Any single port (bit) can be written (set/cleared) at once; or, any sequence of eight ports can be written (set/cleared) in any combination at once. There are no boundaries; it is equally acceptable to write P0 through P7, P1 through P8, or P31 through P38 (P32 through P38 are nonexistent, so the instructions to these bits are ignored).

Using 8-bit control, a seven-segment digit with a decimal point can be updated in a single byte-write, a 14-

segment digit with DP can be updated in two byte-writes, and 16-segment digits with DP can be updated in two byte-writes plus a bit write. Also, discrete LEDs and GPIO port bits can be lit and controlled individually without affecting other ports.

Shutdown

When the MAX6956 is in shutdown mode, all ports are forced to inputs (which can be read), and the pullup current sources are turned off. Data in the port and control registers remain unaltered, so port configuration and output levels are restored when the MAX6956 is taken out of shutdown. The display driver can still be programmed while in shutdown mode. For minimum supply current in shutdown mode, logic inputs should be at GND or V+ potential. Shutdown mode is exited by setting the S bit in the configuration register (Table 8).

MAX6956

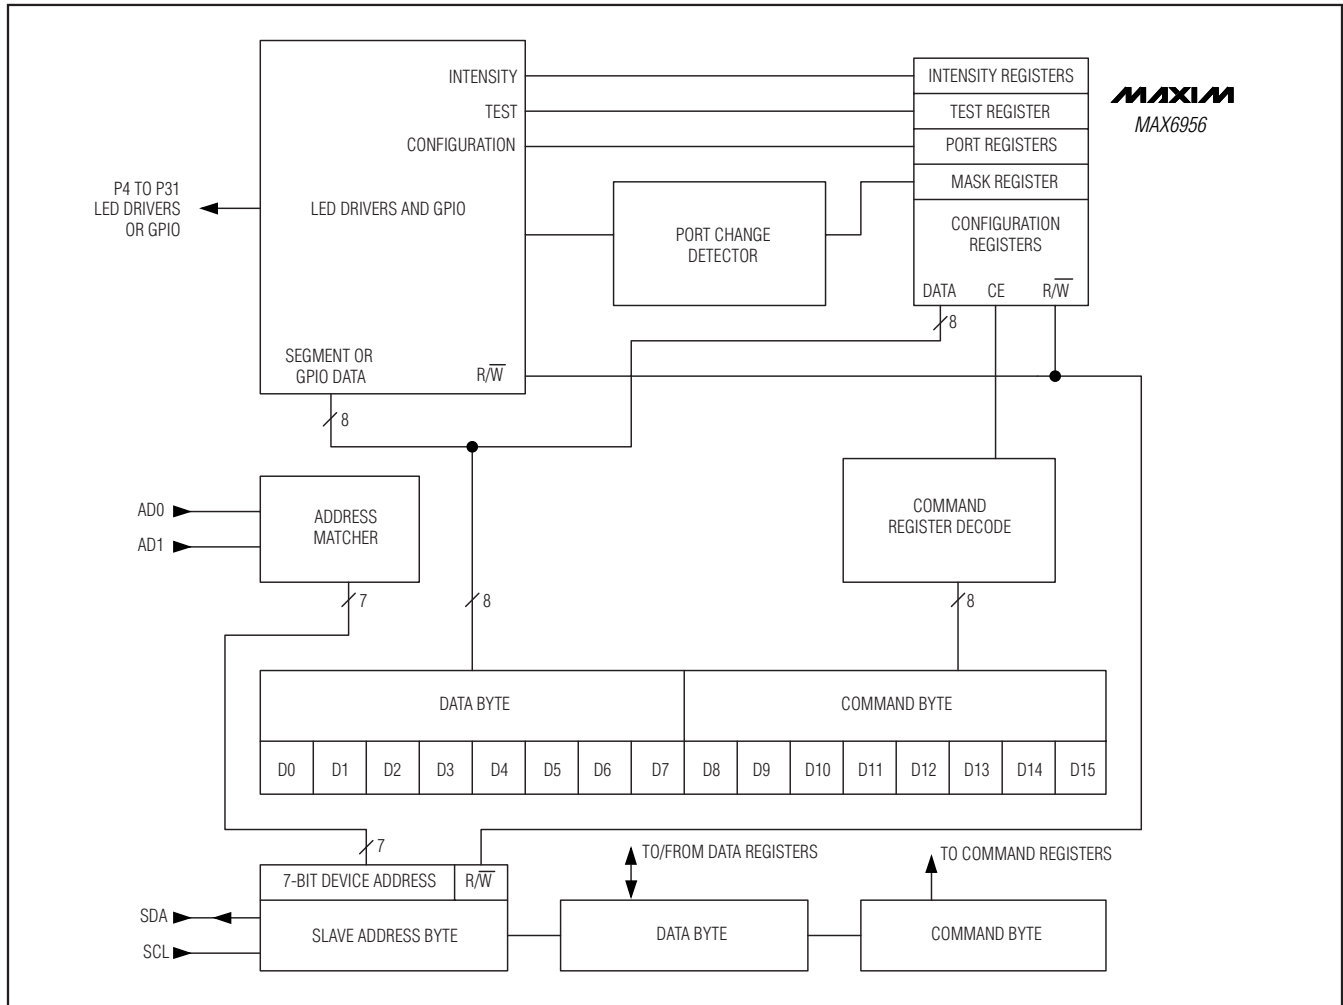

Figure 1. MAX6956 Functional Diagram

Shutdown mode is temporarily overridden by the display test function.

Serial Interface

Serial Addressing

The MAX6956 operates as a slave that sends and receives data through an I²C-compatible 2-wire interface. The interface uses a serial data line (SDA) and a serial clock line (SCL) to achieve bidirectional communication between master(s) and slave(s). A master (typically a microcontroller) initiates all data transfers to and from the MAX6956, and generates the SCL clock that synchronizes the data transfer (Figure 2).

The MAX6956 SDA line operates as both an input and an open-drain output. A pullup resistor, typically 4.7k Ω ,

is required on SDA. The MAX6956 SCL line operates only as an input. A pullup resistor, typically 4.7k Ω , is required on SCL if there are multiple masters on the 2-wire interface, or if the master in a single-master system has an open-drain SCL output.

Each transmission consists of a START condition (Figure 3) sent by a master, followed by the MAX6956 7-bit slave address plus R/W bit (Figure 6), a register address byte, one or more data bytes, and finally a STOP condition (Figure 3).

Start and Stop Conditions

Both SCL and SDA remain high when the interface is not busy. A master signals the beginning of a transmission with a START (S) condition by transitioning SDA from high to low while SCL is high. When the master

2-Wire-Interfaced, 2.5V to 5.5V, 20-Port or 28-Port LED Display Driver and I/O Expander

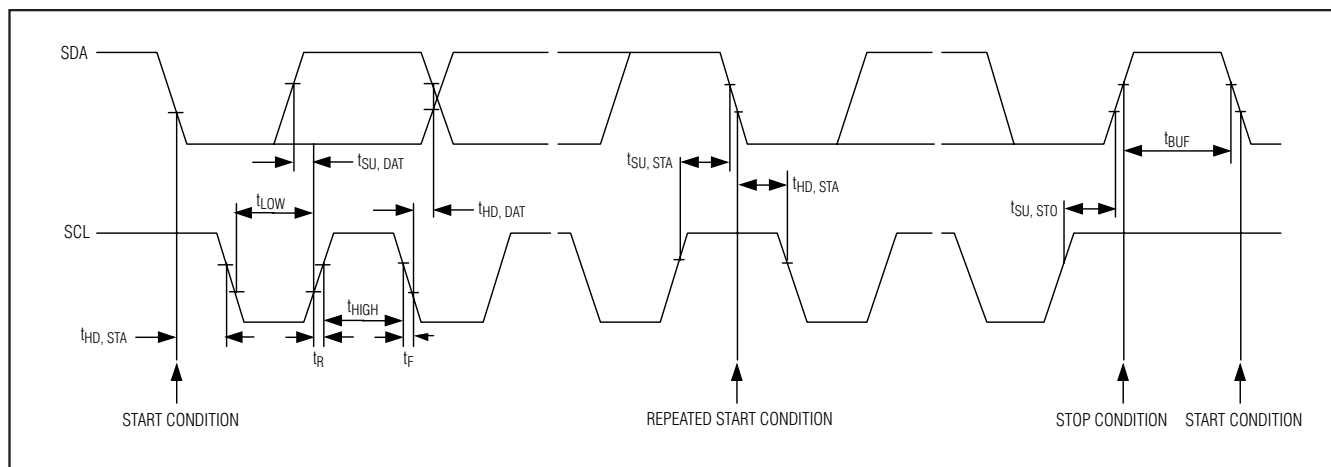

Figure 2. 2-Wire Serial Interface Timing Details

Figure 3. Standard Stop Conditions

Figure 4. Bit Transfer

has finished communicating with the slave, it issues a STOP (P) condition by transitioning SDA from low to high while SCL is high. The bus is then free for another transmission (Figure 3).

Bit Transfer

One data bit is transferred during each clock pulse. The data on SDA must remain stable while SCL is high (Figure 4).

Acknowledge

The acknowledge bit is a clocked 9th bit, which the recipient uses to handshake receipt of each byte of data (Figure 5). Thus, each byte transferred effectively requires 9 bits. The master generates the 9th clock pulse, and the recipient pulls down SDA during the acknowledge clock pulse, such that the SDA line is stable low during the high period of the clock pulse. When the master is transmitting to the MAX6956, the MAX6956 generates the acknowledge bit because the

2-Wire-Interfaced, 2.5V to 5.5V, 20-Port or 28-Port LED Display Driver and I/O Expander

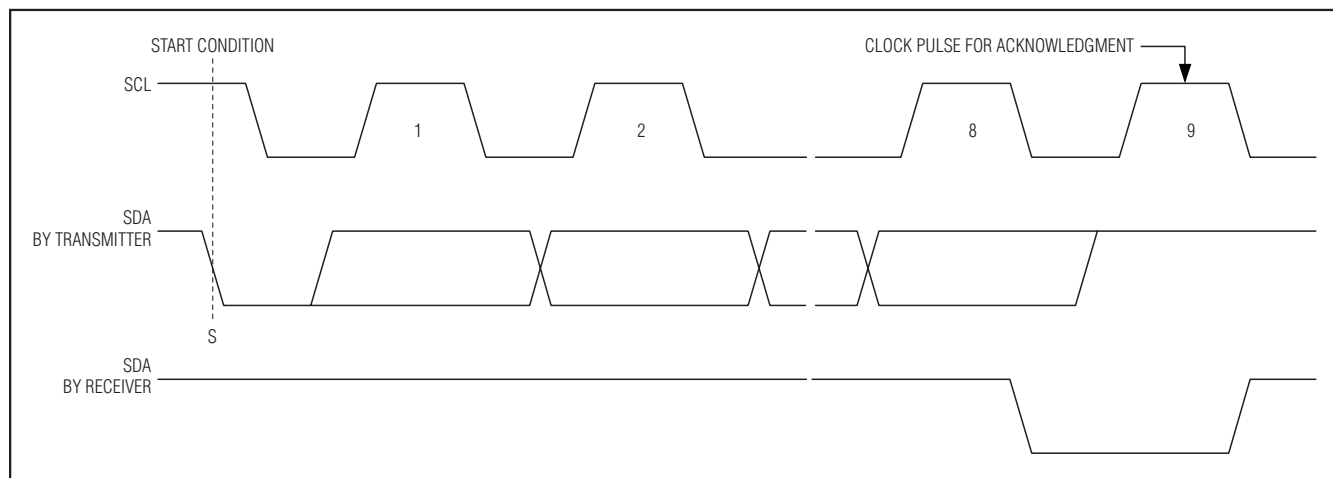

Figure 5. Acknowledge

Figure 6. Slave Address

MAX6956 is the recipient. When the MAX6956 is transmitting to the master, the master generates the acknowledge bit because the master is the recipient.

Slave Address

The MAX6956 has a 7-bit-long slave address (Figure 6). The eighth bit following the 7-bit slave address is the R/W bit. It is low for a write command, high for a read command.

The first 3 bits (MSBs) of the MAX6956 slave address are always 100. Slave address bits A3, A2, A1, and A0 are selected by address inputs, AD1 and AD0. These two input pins may be connected to GND, V+, SDA, or SCL. The MAX6956 has 16 possible slave addresses (Table 3) and therefore, a maximum of 16 MAX6956 devices may share the same interface.

Message Format for Writing the MAX6956

A write to the MAX6956 comprises the transmission of the MAX6956's slave address with the R/W bit set to zero, followed by at least 1 byte of information. The first

byte of information is the command byte. The command byte determines which register of the MAX6956 is to be written by the next byte, if received. If a STOP condition is detected after the command byte is received, then the MAX6956 takes no further action (Figure 8) beyond storing the command byte.

Any bytes received after the command byte are data bytes. The first data byte goes into the internal register of the MAX6956 selected by the command byte (Figure 9). If multiple data bytes are transmitted before a STOP condition is detected, these bytes are generally stored in subsequent MAX6956 internal registers because the command byte address generally autoincrements (Table 4).

Message Format for Reading

The MAX6956 is read using the MAX6956's internally stored command byte as address pointer, the same way the stored command byte is used as address pointer for a write. The pointer generally autoincrements after each data byte is read using the same rules as for a write (Table 4). Thus, a read is initiated by first configuring the MAX6956's command byte by perform-

| COMMAND BYTE ADDRESS RANGE | AUTOINCREMENT BEHAVIOR |
|----------------------------|--|
| x0000000 to x1111110 | Command address autoincrements after byte read or written |
| x1111111 | Command address remains at x1111111 after byte written or read |

ing a write (Figure 8). The master can now read n consecutive bytes from the MAX6956, with the first data byte being read from the register addressed by the initialized command byte. When performing read-after-write verification, remember to reset the command byte's address because the stored control byte address generally has been autoincremented after the write (Table 4). Table 5 is the register address map.

Operation with Multiple Masters

If the MAX6956 is operated on a 2-wire interface with multiple masters, a master reading the MAX6956 should use a repeated start between the write, which sets the MAX6956's address pointer, and the read(s) that takes the data from the location(s). This is because it is possible for master 2 to take over the bus after master 1 has set up the MAX6956's address pointer but before master 1 has read the data. If master 2 subse-

Note: Unused bits read as 0.

quently changes, the MAX6956's address pointer, then master 1's delayed read may be from an unexpected location.

Command Address Autoincrementing

Address autoincrementing allows the MAX6956 to be configured with the shortest number of transmissions by minimizing the number of times the command address needs to be sent. The command address stored in the MAX6956 generally increments after each data byte is written or read (Table 4).

Initial Power-Up

On initial power-up, all control registers are reset, the current registers are set to minimum value, and the MAX6956 enters shutdown mode (Table 6).

LED Current Control

LED segment drive current can be set either globally or individually. Global control simplifies the operation when all LEDs are set to the same current level, because writing just the global current register sets the current for all ports configured as LED segment drivers. It is also possible to individually control the current

drive of each LED segment driver. Individual/global brightness control is selected by setting the configuration register I bit (Table 9). The global current register (0x02) data are then ignored, and segment currents are set using register addresses 0x12 through 0x1F (Tables 12, 13, and 14). Each segment is controlled by a nibble of one of the 16 current registers.

Transition (Port Data Change) Detection

Port transition detection allows any combination of the seven ports P24–P30 to be continuously monitored for changes in their logic status (Figure 11). A detected change is flagged on the transition detection mask register INT status bit, D7 (Table 15). If port P31 is configured as an output (Tables 1 and 2), then P31 also automatically becomes an active-high interrupt output (INT), which follows the condition of the INT status bit. Port P31 is set as output by writing bit D7 = 0 and bit D6 = 1 to the port configuration register (Table 1). Note that the MAX6956 does not identify which specific port(s) caused the interrupt, but provides an alert that one or more port levels have changed.

| Enabled | 0x04 | 1 | I | X | X | X | X | X | S |

The mask register contains 7 mask bits, which select which of the seven ports P24–P30 are to be monitored (Table 15). Set the appropriate mask bit to enable that port for transition detect. Clear the mask bit if transitions on that port are to be ignored. Transition detection works regardless of whether the port being monitored is set to input or output, but generally, it is not particularly useful to enable transition detection for outputs.

To use transition detection, first set up the mask register and configure port P31 as an output, as described above. Then enable transition detection by setting the

M bit in the configuration register (Table 10). Whenever the configuration register is written with the M bit set, the MAX6956 updates an internal 7-bit snapshot register, which holds the comparison copy of the logic states of ports P24 through P30. The update action occurs regardless of the previous state of the M bit, so that it is not necessary to clear the M bit and then set it again to update the snapshot register.

When the configuration register is written with the M bit set, transition detection is enabled and remains enabled until either the configuration register is written

X = Don't care bit.

with the M bit clear, or a transition is detected. The INT status bit (transition detection mask register bit D7) goes low. Port P31 (if enabled as INT output) also goes low, if it was not already low.

Once transition detection is enabled, the MAX6956 continuously compares the snapshot register against the changing states of P24 through P31. If a change on any of the monitored ports is detected, even for a short time (like a pulse), the INT status bit (transition detection mask register bit D7) is set. Port P31 (if enabled as INT output) also goes high. The INT output and INT status bit are not cleared if more changes occur or if the data pattern returns to its original snapshot condition. The only way to clear INT is to access (read or write) the transition detection mask register (Table 15). So if the transition detection mask register is read twice in succession after a transition event, the first time reads with bit D7 set (identifying the event), and the second time reads with bit D7 clear.

Transition detection is a one-shot event. When INT has been cleared after responding to a transition event, transition detection is automatically disabled, even though the M bit in the configuration register remains set (unless cleared by the user). Reenable transition detection by writing the configuration register with the

M bit set, to take a new snapshot of the seven ports P24 to P30.

Display Test Register

Display test mode turns on all ports configured as LED drivers by overriding, but not altering, all controls and port registers, except the port configuration register (Table 16). Only ports configured as LED drivers are affected. Ports configured as GPIO push-pull outputs do not change state. In display test mode, each port's current is temporarily set to 1/2 the maximum current limit as controlled by R_{ISET}.

Selecting External Component R_{ISET} to Set Maximum Segment Current

The MAX6956 uses an external resistor R_{ISET} to set the maximum segment current. The recommended value, 39kΩ, sets the maximum current to 24mA, which makes the segment current adjustable from 1.5mA to 24mA in 1.5mA steps.

To set a different segment current, use the formula:

$$R_{ISET} = 936k\Omega / I_{SEG}$$

where I_{SEG} is the desired maximum segment current.

The recommended value of R_{ISET} is 39k Ω .

The recommended value of R_{ISET} is the minimum allowed value, since it sets the display driver to the maximum allowed segment current. R_{ISET} can be a higher value to set the segment current to a lower maximum value where desired. The user must also ensure that the maximum current specifications of the LEDs connected to the driver are not exceeded.

The drive current for each segment can be controlled through programming either the Global Current register (Table 11) or Individual Segment Current registers (Tables 12, 13, and 14), according to the setting of the Current Control bit of the Configuration register (Table 9). These registers select the LED's constant-current drive from 16 equal fractions of the maximum segment current. The current difference between successive current steps, I_{STEP} , is therefore determined by the formula:

$$I_{STEP} = I_{SEG} / 16$$

If $I_{SEG} = 24\text{mA}$, then $I_{STEP} = 24\text{mA} / 16 = 1.5\text{mA}$.

Applications Information

Driving Bicolor and Tricolor LEDs

Bicolor digits group a red and a green die together for each display element, so that the element can be lit red, green (or orange), depending on which die (or both) is lit. The MAX6956 allows each segment's current to be set individually from 1/16th (minimum current and LED intensity) to 16/16th (maximum current and LED intensity), as well as off (zero current). Thus, a bicolor (red-green) segment pair can be set to 289 color/intensity combinations. A discrete or CA tricolor (red-green-yellow or red-green-blue) segment triad can be set to 4913 color/intensity combinations.

Power Dissipation Issues

Each MAX6956 port can sink a current of 24mA into an LED with a 2.4V forward-voltage drop when operated from a supply voltage of at least 3.0V. The minimum voltage drop across the internal LED drivers is therefore $(3.0V - 2.4V) = 0.6V$. The MAX6956 can sink $28 \times 24\text{mA} = 672\text{mA}$ when all outputs are operating as LED

X = Don't care bit

segment drivers at full current. On a 3.3V supply, a MAX6956 dissipates $(3.3V - 2.4V) \times 672mA = 0.6W$ when driving 28 of these 2.4V forward-voltage drop LEDs at full current. This dissipation is within the ratings of the 36-pin SSOP package with an ambient temperature up to +98°C. If a higher supply voltage is used or the LEDs used have a lower forward-voltage drop than 2.4V, the MAX6956 absorbs a higher voltage, and the MAX6956's power dissipation increases.

If the application requires high drive current and high supply voltage, consider adding a series resistor to each LED to drop excessive drive voltage off-chip. For example, consider the requirement that the MAX6956 must drive LEDs with a 2.0V to 2.4V specified forward-voltage drop, from an input supply range is 5V \pm 5% with a maximum LED current of 20mA. Minimum input supply voltage is 4.75V. Maximum LED series resistor value is $(4.75V - 2.4V - 0.6V)/0.020A = 87.5\Omega$. We choose $82\Omega \pm 2\%$. Worst-case resistor dissipation is at maximum tolerated resistance, i.e., $(0.020A)^2 \times (82\Omega \times 1.02) = 34mW$. The maximum MAX6956 dissipation per LED is at maximum input supply voltage, minimum tolerated resistance, minimum tolerated LED forward-voltage drop, i.e., $0.020 \times (5.25V - 2.0V - (0.020A \times 82\Omega \times 0.98)) = 32.86mW$. Worst-case MAX6956 dissipation is 920mW driving all 28 LEDs at 20mA full current at once, which meets the 941mW dissipation ratings of the 36-pin SSOP package.

Low-Voltage Operation

The MAX6956 operates down to 2V supply voltage (although the sourcing and sinking currents are not guaranteed), providing that the MAX6956 is powered up initially to at least 2.5V to trigger the device's internal reset.

Serial Interface Latency

When a MAX6956 register is written through the I²C interface, the register is updated on the rising edge of SCL during the data byte's acknowledge bit (Figure 5). The delay from the rising edge of SCL to the internal register being updated can range from 50ns to 350ns.

PC Board Layout Considerations

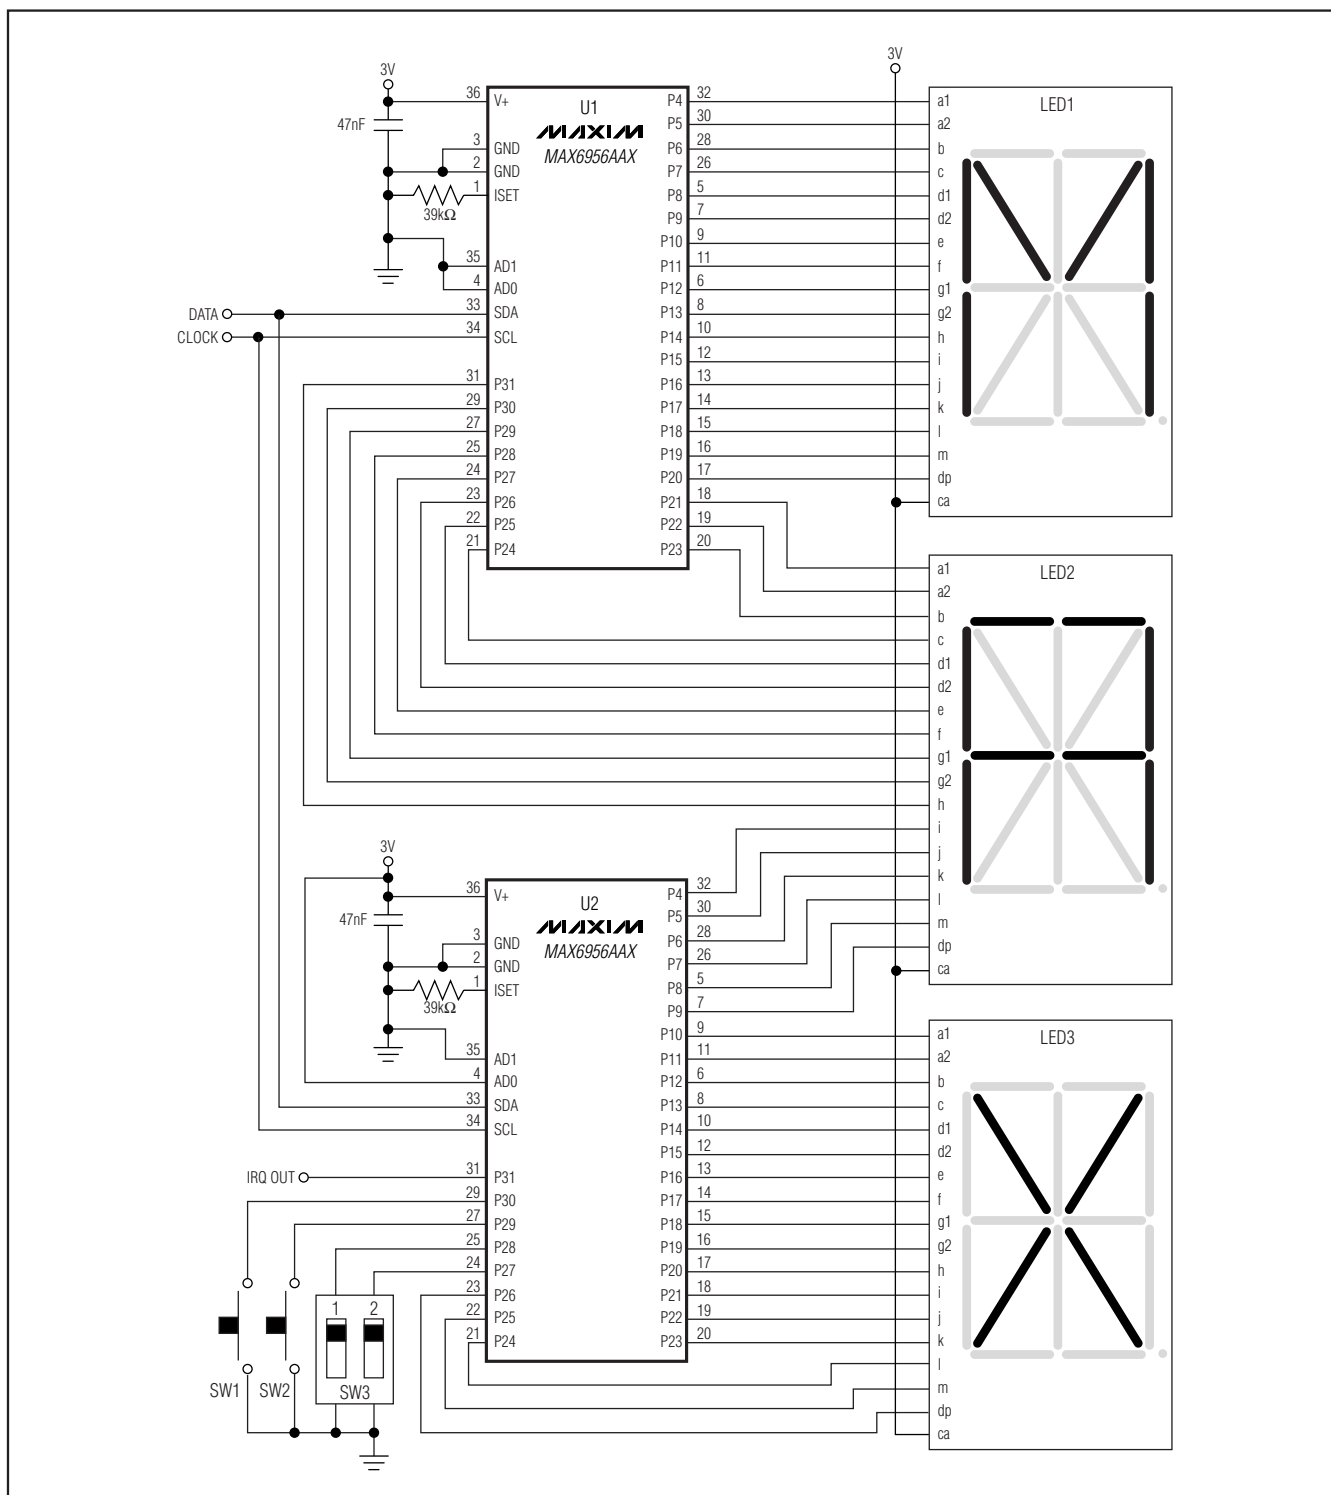

Ensure that all of the MAX6956 GND connections are used. A ground plane is not necessary, but may be useful to reduce supply impedance if the MAX6956 outputs are to be heavily loaded. Keep the track length from the ISET pin to the R_{ISET} resistor as short as possible, and take the GND end of the resistor either to the ground plane or directly to the GND pins.

Power-Supply Considerations

The MAX6956 operates with power-supply voltages of 2.5V to 5.5V. Bypass the power supply to GND with a 0.047 μ F capacitor as close to the device as possible. Add a 1 μ F capacitor if the MAX6956 is far away from the board's input bulk decoupling capacitor.

Вы можете приобрести в компании MosChip.

Для оперативного оформления запроса Вам необходимо перейти по данной ссылке:

<http://moschip.ru/get-element>

Вы можете разместить у нас заказ для любого Вашего проекта, будь то серийное производство или разработка единичного прибора.

В нашем ассортименте представлены ведущие мировые производители активных и пассивных электронных компонентов.

Нашей специализацией является поставка электронной компонентной базы двойного назначения, продукции таких производителей как XILINX, Intel (ex.ALTERA), Vicor, Microchip, Texas Instruments, Analog Devices, Mini-Circuits, Amphenol, Glenair.

Сотрудничество с глобальными дистрибьюторами электронных компонентов, предоставляет возможность заказывать и получать с международных складов практически любой перечень компонентов в оптимальные для Вас сроки.

На всех этапах разработки и производства наши партнеры могут получить квалифицированную поддержку опытных инженеров.

Система менеджмента качества компании отвечает требованиям в соответствии с ГОСТ Р ИСО 9001, ГОСТ РВ 0015-002 и ЭС РД 009
