

Intelligent Power Module and Gate Drive Interface Hermetically Sealed Optocouplers

Data Sheet

Description

The HCPL-530x devices consist of a GaAsP LED optically coupled to an integrated high gain photo detector in a hermetically sealed package. The products are capable of operation and storage over the full military temperature range and can be purchased as either commercial product or with full MIL-PRF-38534 Class Level H or K testing or from the DLA Standard Microcircuit Drawing (SMD) 5962-96852. All devices are manufactured and tested on a MIL-PRF-38534 certified line, and Class H and K devices are included in the DLA Qualified Manufacturers List QML-38534 for Hybrid Microcircuits. Minimized propagation delay difference between devices makes these optocouplers excellent solutions for improving inverter efficiency through reduced switching dead time. An on-chip 20-k Ω output pull-up resistor can be enabled by shorting output pins 6 and 7, thus eliminating the need for an external pull-up resistor in common IPM applications. Specifications and performance plots are given for typical IPM applications.

CAUTION It is advised that normal static precautions be taken in handling and assembly of this component to prevent damage and/or degradation which may be induced by ESD.

Features

- Performance specified over full military temperature Range: -55°C to +125°C
- Fast maximum propagation delays
 - t_{PHL} = 450 ns
 - t_{PLH} = 650 ns
- Minimized pulse width distortion (PWD = 450 ns)
- High common mode rejection (CMR): 10 kV/ μ s at V_{CM} = 1000V
- CTR > 30% at I_F = 10 mA
- 1500 Vdc withstand test voltage
- Manufactured and tested on a MIL-PRF-38534 certified line
- Hermetically sealed packages
- Dual marked with device part number and DLA Standard Microcircuit Drawing (SMD)
- QML-38534, Class H and K
- HCPL-4506 function compatibility

Applications

- Military and space
- High reliability systems
- Harsh industrial environments
- Transportation, medical, and life critical systems
- IPM isolation
- Isolated IGBT/MOSFET gate drive
- AC and brushless DC motor drives
- Industrial inverters

1. See [Selection Guide—Lead Configuration Options](#) for available extensions.

- Commercial parts receive 100% testing at 25°C (Subgroups 1 and 9). SMD, Class H and K parts receive 100% testing at 25°C , $+125^\circ\text{C}$, and -55°C (Subgroups 1 and 9, 2 and 10, 3 and 11 respectively).
- All typical values at 25°C , $V_{CC} = 15\text{V}$.
- Current Transfer Ratio in percent is defined as the ratio of output collector current (I_O) to the forward LED input current (I_F) times 100.
- Use of a $0.1\text{ }\mu\text{F}$ bypass capacitor connected between pins 5 and 8 can improve performance by filtering power supply line noise.
- Device considered a two-terminal device: Pins 1, 2, 3, and 4 shorted together and Pins 5, 6, 7, and 8 shorted together.
- The internal $20\text{ k}\Omega$ resistor can be used by shorting pins 6 and 7 together.
- Due to the tolerance of the internal resistor, and since propagation delay is dependent on the load resistor value, performance can be improved by using an external $20\text{ k}\Omega$ 1% load resistor. For more information on how propagation delay varies with load resistance, see [Figure 8](#).
- The $R_L = 20\text{ k}\Omega$, $C_L = 100\text{ pF}$ represents a typical IPM (Intelligent Power Module) load.

Switching Specifications ($R_L = 20\text{ k}\Omega$ External)

Over recommended operating conditions ($T_A = -55^\circ\text{C}$ to $+125^\circ\text{C}$, $V_{CC} = +4.5\text{V}$ to 30V , $I_{F(ON)} = 10\text{ mA}$ to 20 mA , $V_{F(OFF)} = -5\text{V}$ to 0.8V) unless otherwise specified.

LED Drive Circuit Considerations for Ultra High CMR Performance

Without a detector shield, the dominant cause of optocoupler CMR failure is capacitive coupling from the input side of the optocoupler, through the package, to the detector IC as shown in [Figure 14](#). The HCPL-530x improves CMR performance by using a detector IC with an optically transparent Faraday shield, which diverts the capacitively coupled current away from the sensitive IC circuitry. However, this shield does not eliminate the capacitive coupling between the LED and the optocoupler output pins and output ground as shown in [Figure 15](#). This capacitive coupling causes perturbations in the LED current during common mode transients and becomes the major source of CMR failures for a shielded optocoupler. The main design objective of a high CMR LED drive circuit becomes keeping the LED in the proper state (on or off) during common mode transients. For example, the recommended application circuit ([Figure 13](#)), can achieve 10 kV/μs CMR while minimizing component complexity. Note that a CMOS gate is recommended in [Figure 13](#) to keep the LED off when the gate is in the high state.

Another cause of CMR failure for a shielded optocoupler is direct coupling to the optocoupler output pins through C_{LEDO1} and C_{LEDO2} in [Figure 15](#). Many factors influence the effect and magnitude of the direct coupling including the use of an internal or external output pull-up resistor, the position of the LED current setting resistor, the connection of the unused input package pins, and the value of the capacitor at the optocoupler output (CL).

Techniques to keep the LED in the proper state and minimize the effect of the direct coupling are discussed in the next two sections.

CMR With the LED on (CMR_L)

A high CMR LED drive circuit must keep the LED on during common mode transients. This is achieved by overdriving the LED current beyond the input threshold so that it is not pulled below the threshold during a transient. The recommended minimum LED current of 10 mA provides adequate margin over the maximum I_{TH} of 5.0 mA (see [Figure 1](#)) to achieve 10 kV/μs CMR. Capacitive coupling is higher when the internal load resistor is used (due to C_{LEDO2}) and an $I_F = 16$ mA is required to obtain 10 kV/μs CMR.

The placement of the LED current setting resistor affects the ability of the drive circuit to keep the LED on during transients and interacts with the direct coupling to the optocoupler output. For example, the LED resistor in [Figure 16](#) is connected to the anode. [Figure 17](#) shows the AC equivalent circuit for [Figure 16](#) during common mode transients. During a $+dV_{CM/dt}$ in [Figure 17](#), the current available at the LED anode (I_{TOTAL}) is limited by the series resistor. The LED current (I_F) is reduced from its DC value by an amount equal to the current that flows through C_{LEDP} and C_{LEDO1} . The situation is made worse because the current through C_{LEDO1} has the effect of trying to pull the output high (toward a CMR failure) at the same time the LED current is being reduced. For this reason, the recommended LED drive circuit ([Figure 13](#)) places the current setting resistor in series with the LED cathode. [Figure 18](#) is the AC equivalent circuit for [Figure 13](#) during common mode transients. In this case, the LED current is not reduced during a $+dV_{CM/dt}$ transient because the current flowing through the package capacitance is supplied by the power supply. During a $dV_{CM/dt}$ transient, however, the LED current is reduced by the amount of current flowing through C_{LEDN} . But better CMR performance is achieved since the current flowing in C_{LEDO1} during a negative transient acts to keep the output low.

Coupling to the LED and output pins is also affected by the connection of pins 1 and 4. If CMR is limited by perturbations in the LED on current, as it is for the recommended drive circuit ([Figure 13](#)), pins 1 and 4 should be connected to the input circuit common. However, if CMR performance is limited by direct coupling to the output when the LED is off, pins 1 and 4 should be left unconnected.

CMR with the LED Off (CMR_H)

A high CMR LED drive circuit must keep the LED off ($V_F \leq V_{F(OFF)}$) during common mode transients. For example, during a $+dV_{CM}/dt$ transient in [Figure 18](#), the current flowing through C_{LEDN} is supplied by the parallel combination of the LED and series resistor. As long as the voltage developed across the resistor is less than $V_{F(OFF)}$, the LED remains off and no common mode failure occurs. Even if the LED momentarily turns on, the 100 pF capacitor from pins 6-5 will keep the output from dipping below the threshold. The recommended LED drive circuit ([Figure 13](#)) provides about 10V of margin between the lowest optocoupler output voltage and a 3V IPM threshold during a 10 kV/ μ s transient with $V_{CM} = 1000V$. Additional margin can be obtained by adding a diode in parallel with the resistor, as shown by the dashed line connection in [Figure 18](#), to clamp the voltage across the LED below $V_{F(OFF)}$.

Since the open collector drive circuit, shown in [Figure 19](#), cannot keep the LED off during a $+dV_{CM}/dt$ transient, it is not desirable for applications requiring ultra high CMR_H performance. [Figure 20](#) is the AC equivalent circuit for [Figure 16](#) during common mode transients. Essentially all the current flowing through C_{LEDN} during a $+dV_{CM}/dt$ transient must be supplied by the LED. CMR_H failures can occur at dv/dt rates where the current through the LED and C_{LEDN} exceeds the input threshold. [Figure 21](#) is an alternative drive circuit which does achieve ultra high CMR performance by shunting the LED in the off state.

IPM Dead Time and Propagation Delay Specifications

These devices include a Propagation Delay Difference specification intended to help designers minimize *dead time* in their power inverter designs. Dead time is the time period during which both the high and low side power transistors (Q1 and Q2 in [Figure 22](#)) are off. Any overlap in Q1 and Q2 conduction results in large currents flowing through the power devices between the high and low voltage motor rails.

To minimize dead time, the designer must consider the propagation delay characteristics of the optocoupler as well as the characteristics of the IPM IGBT gate drive circuit. Considering only the delay characteristics of the optocoupler (the characteristics of the IPM IGBT gate drive circuit can be analyzed in the same way), it is important to know the minimum and maximum turn-on (t_{PHL}) and turn-off (t_{PLH}) propagation delay specifications, preferably over the desired operating temperature range.

The limiting case of zero dead time occurs when the input to Q1 turns off at the same time that the input to Q2 turns on. This case determines the minimum delay between LED1 turn-off and LED2 turn-on, which is related to the worst-case optocoupler propagation delay waveforms, as shown in [Figure 23](#). A minimum dead time of zero is achieved in [Figure 23](#) when the signal to turn on LED2 is delayed by ($t_{PLHmax} - t_{PHLmin}$) from the LED1 turn off. This delay is the maximum value for the propagation delay difference specification which is specified at 500 ns for the HCPL-530x over an operating temperature range of $-55^{\circ}C$ to $+125^{\circ}C$.

Delaying the LED signal by the maximum propagation delay difference ensures that the minimum dead time is zero, but it does not tell a designer what the maximum dead time will be. The maximum dead time occurs in the highly unlikely case where one optocoupler with the fastest t_{PLH} and another with the slowest t_{PHL} are in the same inverter leg. The maximum dead time in this case becomes the sum of the spread in the t_{PLH} and t_{PHL} propagation delays as shown in [Figure 24](#). The maximum dead time is also equivalent to the difference between the maximum and minimum propagation delay difference specifications. The maximum dead time (due to the optocouplers) for the HCPL-530x is 670 ns ($= 500 \text{ ns} - (-170 \text{ ns})$) over an operating temperature range of $-55^{\circ}C$ to $+125^{\circ}C$.

140	520	220

Graph showing the propagation delay (t_p) in nanoseconds (ns) versus the load resistance (R_L) in kilohms ($K\Omega$) for a 74123 monostable multivibrator. The circuit parameters are: $I_F = 10\text{ mA}$, $V_{CC} = 15\text{ V}$, $C_L = 100\text{ pF}$, and $T_A = 25^\circ\text{C}$.

The graph displays two curves: t_{PLH} (solid line) and t_{PHL} (dashed line). The x-axis ranges from 0 to 50 $K\Omega$, and the y-axis ranges from 0 to 800 ns. The t_{PLH} curve starts at approximately 150 ns for $R_L = 0$ and increases linearly to about 750 ns at $R_L = 50\text{ K}\Omega$. The t_{PHL} curve starts at approximately 250 ns for $R_L = 0$, decreases to about 200 ns at $R_L = 10\text{ K}\Omega$, and then remains constant at 200 ns for higher load resistances.

R_L ($K\Omega$)	t_{PLH} (ns)	t_{PHL} (ns)
0	150	250
10	300	200
20	450	200
30	600	200
40	750	200
50	900	200

The graph shows the propagation delay (t_p) in nanoseconds (ns) on the y-axis versus the load capacitance (CL) in picofarads (pF) on the x-axis. The y-axis ranges from 0 to 1400 ns in increments of 200. The x-axis ranges from 0 to 500 pF in increments of 100. Two curves are plotted: a solid line for t_{PLH} and a dashed line for t_{PHL} . Both curves start at approximately 120 ns at 0 pF. The t_{PLH} curve rises more steeply, reaching about 1350 ns at 500 pF. The t_{PHL} curve rises more gradually, reaching about 600 ns at 500 pF. A legend in the top left corner specifies the test conditions: $I_F = 10 \text{ mA}$, $V_{CC} = 15 \text{ V}$, $R_L = 20 \text{ k}\Omega$, and $T_A = 25^\circ\text{C}$.

CL (pF)	t_{PLH} (ns)	t_{PHL} (ns)
0	120	120
100	350	200
200	600	300
300	850	400
400	1100	500
500	1350	600

NOTE: THE PROPAGATION DELAYS USED TO CALCULATE PDD ARE TAKEN AT EQUAL TEMPERATURES.

Figure 24 Waveforms for Dead Time Calculations

MAXIMUM DEAD TIME (DUE TO OPTOCOUPLER)

$$= (t_{PLH} \text{ MAX.} - t_{PLH} \text{ MIN.}) + (t_{PHL} \text{ MAX.} - t_{PHL} \text{ MIN.})$$

$$= (t_{PLH} \text{ MAX.} - t_{PHL} \text{ MIN.}) - (t_{PLH} \text{ MIN.} - t_{PHL} \text{ MAX.})$$

$$= PDD^* \text{ MAX.} - PDD^* \text{ MIN.}$$

*PDD = PROPAGATION DELAY DIFFERENCE

NOTE: THE PROPAGATION DELAYS USED TO CALCULATE THE MAXIMUM DEAD TIME ARE TAKEN AT EQUAL TEMPERATURES.

Данный компонент на территории Российской Федерации

Вы можете приобрести в компании MosChip.

Для оперативного оформления запроса Вам необходимо перейти по данной ссылке:

<http://moschip.ru/get-element>

Вы можете разместить у нас заказ для любого Вашего проекта, будь то серийное производство или разработка единичного прибора.

В нашем ассортименте представлены ведущие мировые производители активных и пассивных электронных компонентов.

Нашей специализацией является поставка электронной компонентной базы двойного назначения, продукции таких производителей как XILINX, Intel (ex.ALTERA), Vicor, Microchip, Texas Instruments, Analog Devices, Mini-Circuits, Amphenol, Glenair.

Сотрудничество с глобальными дистрибьюторами электронных компонентов, предоставляет возможность заказывать и получать с международных складов практически любой перечень компонентов в оптимальные для Вас сроки.

На всех этапах разработки и производства наши партнеры могут получить квалифицированную поддержку опытных инженеров.

Система менеджмента качества компании отвечает требованиям в соответствии с ГОСТ Р ИСО 9001, ГОСТ РВ 0015-002 и ЭС РД 009

Офис по работе с юридическими лицами:
