GENERAL DESCRIPTION

The [ADG441](#), [ADG442](#), and [ADG444](#) are monolithic CMOS devices that comprise of four independently selectable switches. They are designed on an enhanced LC²MOS process that provides low power dissipation yet gives high switching speed and low on resistance.

The on resistance profile is very flat over the full analog input range, which ensures good linearity and low distortion when switching audio signals. High switching speed also makes the parts suitable for video signal switching. CMOS construction ensures ultralow power dissipation, making the parts ideally suited for portable and battery-powered instruments. The [ADG441](#), [ADG442](#), and [ADG444](#) contain four independent SPST switches. Each switch of the [ADG441](#) and [ADG444](#) turns on when a logic low is applied to the appropriate control input. The [ADG442](#) switches are turned on with logic high on the appropriate control input. The [ADG441](#) and [ADG444](#) switches differ in that the [ADG444](#) requires a 5 V logic power supply that is applied to the V_L pin. The [ADG441](#) and [ADG442](#) do not have a V_L pin, the logic power supply is generated internally by an on-chip voltage generator.

FUNCTIONAL BLOCK DIAGRAM

Figure 1.

Each switch conducts equally well in both directions when ON and has an input signal range that extends to the power supplies. In the OFF condition, signal levels up to the supplies are blocked. All switches exhibit break-before-make switching action for use in multiplexer applications. Inherent in the design is the low charge injection for minimum transients when switching the digital inputs.

PRODUCT HIGHLIGHTS

1. Extended signal range. The [ADG441A/ADG442A/ADG444A](#) are fabricated on an enhanced LC²MOS, trench-isolated process, giving an increased signal range that extends to the supply rails.
2. Low power dissipation.
3. Low R_{ON}.
4. Trench isolation guards against latch-up for A grade parts. A dielectric trench separates the P and N channel transistors thereby preventing latch-up even under severe overvoltage conditions.
5. Break-before-make switching. This prevents channel shorting when the switches are configured as a multiplexer.
6. Single-supply operation. For applications where the analog signal is unipolar, the [ADG441/ADG442/ADG444](#) can be operated from a single-rail power supply. The parts are fully specified with a single 12 V power supply.

TRENCH ISOLATION

In the [ADG441A](#), [ADG442A](#), and [ADG444A](#), an insulating oxide layer (trench) is placed between the NMOS and the PMOS transistors of each CMOS switch. Parasitic junctions, which occur between the transistors in junction isolated switches, are eliminated, and the result is a completely latch-up proof switch.

In junction isolation, the N and P wells of the PMOS and NMOS transistors form a diode that is reverse-biased under normal operation. However, during overvoltage conditions, this diode becomes forward-biased. A silicon-controlled rectifier (SCR) type circuit is formed by the two transistors causing a significant amplification of the current which, in turn, leads to latch-up. With trench isolation, this diode is removed, and the result is a latch-up proof switch.
