8	0b RO	Card Interrupt (crd_int): Writing this bit to 1 does not clear this bit. It is cleared by resetting the SD card interrupt factor. In 1-bit mode, the Host Controller shall detect the Card Interrupt without SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so there are some sample delays between the interrupt signal from the SD card and the interrupt to the Host System. When this status has been set and the Host Driver needs to start this interrupt service, Card Interrupt Status Enable in the Normal Interrupt Status Enable register may be set to 0 in order to clear the card interrupt statuses latched in the Host Controller and to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset interrupt factors in the SD card and the interrupt signal may not be asserted), set Card Interrupt Status Enable to 1 and start sampling the interrupt signal again. Interrupt detected by DAT[1] is supported when there is a card per slot. In case of shared bus, interrupt pins are used to detect interrupts. If 000b is set to Interrupt Pin Select in the Shared Bus Control register, this status is effective. Non-zero value is set to Interrupt Pin Select, INT_A, INT_B or INT_C is then used to device interrupts. 1 = Generate Card Interrupt 0 = No Card Interrupt
7	0b RW/1C	Card Removal (crd_rm): This status is set if the Card Inserted in the Present State register changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card detect state may possibly be changed when the Host Driver clear this bit and interrupt event may not be generated. 1 = Card removed 0 = Card state stable or Debouncing
6	0b RW/1C	Card Insertion (crd_ins): This status is set if the Card Inserted in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed, because the card detect state may possibly be changed when the Host Driver clears this bit and interrupt event may not be generated. 1 Card inserted 0 Card state stable or Debouncing
5	0b RW/1C	Buffer Read Ready (buf_rd_rdy): This status is set if the Buffer Read Enable changes from 0 to 1. Refer to the Buffer Read Enable in the Present State register. While performing tuning procedure (Execute Tuning is set to 1), Buffer Read Ready is set to 1 for every CMD19 execution. 1 = Ready to read buffer 0 = Not ready to read buffer
4	0b RW/1C	Buffer Write Ready (buf_wr_rdy): This status is set if the Buffer Write Enable changes from 0 to 1. Refer to the Buffer Write Enable in the Present State register. 1 = Ready to write buffer 0 = Not ready to write buffer
3	0b RW/1C	DMA Interrupt (dma_int): This status is set if the Host Controller detects the Host SDMA Buffer boundary during transfer. Refer to the Host SDMA Buffer Boundary in the Block Size register. Other DMA interrupt factors may be added in the future. In case of ADMA, by setting Int field in the descriptor table, Host Controller generates this interrupt. Suppose that it is used for debugging. This interrupt shall not be generated after the Transfer Complete. 1 = DMA Interrupt is generated 0 = No DMA Interrupt
2	0b RW/1C	Block Gap Event (blk_gap_event): If the Stop At Block Gap Request in the Block Gap Control register is set, this bit is set when both a read / write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1. (1) In the case of a Read Transaction This bit is set at the falling edge of the DAT Line Active Status, when the transaction is stopped at SD Bus timing. The Read Wait shall be supported in order to use this function. Refer to Section 3.12.3 for timing details. p1(1) In the case of a Write Transaction This bit is set at the falling edge of Write Transfer Active Status (after getting CRC status at SD Bus timing). Refer to Section 3.12.4 for more details on the sequence of events. 1 = Transaction stopped at block gap 0 = No Block Gap Event

Bit Range	Default & Access	Field Name (ID): Description
1	0b RW/1C	Transfer Complete (tx_comp): This bit is set when a read / write transfer and a command with busy is completed. (1) In the case of a Read Transaction This bit is set at the falling edge of Read Transfer Active Status. This interrupt is generated in two cases. The first is when a data transfer is completed as specified by data length (After the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request in the Block Gap Control register (After valid data has been read to the Host System). Refer to Section 3.12.3 for more details on the sequence of events. (2) In the case of a Write Transaction This bit is set at the falling edge of the DAT Line Active Status. This interrupt is generated in two cases. The first is when the last data is written to the SD card as specified by data length and the busy signal released. The second is when data transfers are stopped at the block gap by setting Stop At Block Gap Request in the Block Gap Control register and data transfers completed. (After valid data is written to the SD card and the busy signal released). Refer to Section 3.12.4 for more details on the sequence of events. (3) In the case of a command with busy This bit is set when busy is de-asserted. Refer to DAT Line Active and Command Inhibit (DAT) in the Present State register. Refer to the spec for the relationship between Transfer Complete and Data Timeout Error. 1 = Command execution is completed 0 = Not complete While performing tuning procedure (Execute Tuning is set to 1), Transfer Complete is not set to 1.
0	0b RW/1C	Command Complete (cmd_comp): This bit is set when get the end bit of the command response. Auto CMD12 and Auto CMD23 consist of two responses. Command Complete is not generated by the response of CMD12 or CMD23 but generated by the response of a read/write command. Refer to Command Inhibit (CMD) in the Present State register for how to control this bit. Command Timeout Error has higher priority than Command Complete. If both bits are set to 1, it can be considered that the response was not received correctly. For a tabular description of the relationship between these two bits, refer to the description of Command Complete in the spec. 1 = Command complete 0 = No command complete

16.6.21 Error Interrupt Status Register (ERR_INT_STATUS)—Offset 32h

Signals defined in this register can be enabled by the Error Interrupt Status Enable register, but not by the Error Interrupt Signal Enable register. The interrupt is generated when the Error Interrupt Signal Enable is enabled and at least one of the statuses is set to 1. Writing to 1 clears the bit, and writing to 0 keeps the bit unchanged. More than one status can be cleared at the one register write.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + 32h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:17, F:0] + 10h

Default: 0000h

0	0	0	0	0
0	0	0	0	0
0	0	0	0	0
0	0	0	0	0
0	0	0	0	0

Bit Range	Default & Access	Field Name (ID): Description
15	0b RW	Vendor Specific Error Status (vend_spec_err_status): Reserved.
14	0b RW	Boot Command Timeout Error (boot_cmd_timeout_err): Occur if the boot are access command is issued to the agent which has no permission to access the boot area.
13	0b RW	CEATA Error (ceata_err): Occurs when ATA command termination has occured due to an error condition the device has encountered.
12	0b RW	Target Response Error (tgt_rsp_err): Occurs when detecting ERROR in m_hresp(dma transaction).
11:10	0h RO	Reserved (rsvd): Reserved.
9	0b RW	ADMA Error (adma_err): This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. 0 = error 1 = no error
8	0b RW	Auto CMD12 Error (cmd12_err): Auto CMD12 and Auto CMD23 use this error status. This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error Status register has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error. 1 = error 0 = no error
7	0b RW	Current Limit Error (cur_limit_err): By setting the SD Bus Power bit in the Power Control register, the Host Controller is requested to supply power for the SD Bus. If the Host Controller supports the Current Limit function, it can be protected from an illegal card by stopping power supply to the card in which case this bit indicates a failure status. Reading 1 means the Host Controller is not supplying power to SD card due to some failure. Reading 0 means that the Host Controller is supplying power and no error has occurred. The Host Controller may require some sampling time to detect the current limit. If the Host Controller does not support this function, this bit shall always be set to 0. 1 = power fail 0 = no error
6	0b RW	Data End Bit Error (data_end_bit_err): Occurs either when detecting 0 at the end bit position of read data which uses the DAT line or at the end bit position of the CRC Status. 1 = error 0 = no error
5	0b RW	Data CRC Error (data_crc_err): Occurs when detecting CRC error when transferring read data which uses the DAT line or when detecting the Write CRC status having a value of other than 010b.
4	0b RW	Data Timeout Error (data_timeout_err): This bit is set when detecting one of following timeout conditions. - Busy timeout for R1b,R5b type - Busy timeout after Write CRC status - Write CRC Status timeout - Read Data timeout 1 = time out 0 = no error

Bit Range	Default & Access	Field Name (ID): Description
3	0b RW	Command Index Error (cmd_index_err): This bit is set if a Command Index error occurs in the command response. 1 = error 0 = no error
2	0b RW	Command End Bit Error (cmd_end_bit_err): This bit is set when detecting that the end bit of a command response is 0. 1 = End Bit Error generated 0 = no error
1	0b RW	Command CRC Error (cmd_crc_err): Command CRC Error is generated in two cases. If a response is returned and the Command Timeout Error is set to 0 (indicating no timeout), this bit is set to 1 when detecting a CRC error in the command response. The Host Controller detects a CMD line conflict by monitoring the CMD line when a command is issued. If the Host Controller drives the CMD line to 1 level, but detects 0 level on the CMD line at the next SD clock edge, then the Host Controller shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict (refer to tabular data in the spec. that explains the relationship between Command CRC Error and Command Timeout Error). 1 = CRC Error Generated. 0 = no error
0	0b RW	Command Timeout Error (cmd_timeout_err): This bit is set only if no response is returned within 64 SD clock cycles from the end bit of the command. If the Host Controller detects a CMD line conflict (in which case Command CRC Error shall also be set, as shown in tabular data in the spec that explains the relationship between this bit and Command CRC Error) this bit shall be set without waiting for 64 SD clock cycles, because the command will be aborted by the Host Controller. 1 = time out 0 = no Error

16.6.22 Normal Interrupt Status Enable (NRM_INT_STATUS_EN)—Offset 34h

Setting to 1 enables Interrupt Status. **Implementation Note:** The Host Controller may sample the card interrupt signal during interrupt period, and may hold its value in the flip-flop. If the **Card Interrupt Status Enable** is set to 0, the Host Controller shall clear all internal signals regarding Card Interrupt.

Access Method

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:17, F:0] + 10h

Default: 00000000h

[illegible]

Bit Range	Default & Access	Field Name (ID): Description
31	0b RW	Preset Value (preset_value): Host Controller Version 3.00 supports this bit. As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set to automatic This bit enables the functions defined in the Preset Value registers. 1 = Automatic Selection by Preset Value are Enabled 0 SDCLK and Driver Strength are controlled by Host Driver If this bit is set to 0, SDCLK Frequency Select, Clock Generator Select in the Clock Control register and Driver Strength Select in Host Control 2 register are set by Host Driver. If this bit is set to 1, SDCLK Frequency Select, Clock Generator Select in the Clock Control register and Driver Strength Select in Host Control 2 register are set by Host Controller as specified in the Preset Value registers.
30	0b RW	Asynchronous Interrupt (async_int): This bit can be set to 1 if a card support asynchronous interrupt and Asynchronous Interrupt Support is set to 1 in the Capabilities register. Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver Card Interrupt to the host when it is asserted by the Card. Usage: It is recommended that Synchronous Interrupt mode be used for SDIO Controller by setting this be to '0'. If Asynchronous Interrupt Enable mode is used, it is required that this bit remain '0' until SD initialization sequence is complete. 1 = Enabled 0 = Disabled

2	0b RW	Force Event for Auto CMD12 CRC Error (cmd12_crc_err): 1 = Interrupt is generated 0 = No Interrupt
1	0b RW	Force Event for Auto CMD12 Timeout Error (cmd12_timeout_err): 1 = Interrupt is generated 0 = No Interrupt
0	0b RW	Force Event for Auto CMD12 Not Executed (cmd12_not_exe): 1 = Interrupt is generated 0 = No Interrupt

16.6.31 Force Event Register for Error Interrupt Status (FORCE_EVENT_ERR_INT_STAT)—Offset 52h

Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register if the corresponding bit of the Error Interrupt Status Enable Register is set.

- Writing 1 : set each bit of the Error Interrupt Status Register
- Writing 0 : no effect

Note: By setting this register, the Error Interrupt can be set in the Error Interrupt Status register. In order to generate interrupt signal, both the Error Interrupt Status Enable and Error Interrupt Signal Enable shall be set.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + 52h

0	0b RW	Force Event for Command Timeout Error (cmd_timeout_err): 1 = Interrupt is generated 0 No Interrupt

16.6.32 ADMA Error Status Register (ADMA_ERR_STAT)—Offset 54h

When ADMA Error Interrupt occurs, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. To recover from the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
- ST_CADR: This state is never set because do not generate ADMA error in this state.

- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 54h

BAR Type: PCI Configuration Register (Size: 32 bits)

Bit Range	Default & Access	Field Name (ID): Description
30:24	0h RW	Back-End Power Control (pwr_ctrl): Each bit of this field controls back-end power supply for an embedded device. Host interface voltage (VDDH) is not controlled by this field. The number of devices supported is specified by Number of Clock Pins, and a maximum of 7 devices can be controlled. - D24 Back-end Power Control for Device 1 - D25 Back-end Power Control for Device 2 - D26 Back-end Power Control for Device 3 - D27 Back-end Power Control for Device 4 - D28 Back-end Power Control for Device 5 - D29 Back-end Power Control for Device 6 - D30 Back-end Power Control for Device 7 The function of each bit is defined as follows: 0 = Back-end Power is Off 1 = Back-end Power is Supplied Back-End power control is effective for embedded memory devices in the Sleep State that support the Sleep command (CMD14) to reduce power consumption and embedded SDIO devices when IOEx is set to 0.
23	0b RO	RSVD1: Reserved
22:20	0h RW	Interrupt Pin Select (int_pin): Interrupt pin inputs are enabled by this field. Enable of unsupported interrupt pin is meaningless. 000b = Interrupt is detected by the Interrupt Cycle. - xx1b = INT_A is enabled - x1xb = INT_B is enabled 1xxb = INT_C is enabled
19	0b RO	RSVD2: Reserved
18:16	0h RW	Clock Pin Select (clk_pin): One of clock pin outputs is selected by this field. Selection of unsupported clock pins is meaningless. Refer to Figure 2-38 for the timing of clock outputs. 000b = Clock Pins are disabled 001b = CLK[1] is selected 010b = CLK[2] is selected ... 111b = CLK[7] is Selected
15	0b RO	RSVD3: Reserved
14:8	0h RO	Bus Width Preset (bus_width): Shared bus supports mixing of 4-bit and 8-bit bus width devices. Each bit of this field specifies the bus width for each embedded device. The number of devices supported is specified by Number of Clock Pins, and a maximum of 7 devices are supported. This field is effective when multiple devices are connected to a shared bus (Slot Type is set to 10b in the Capabilities register). In the other case, Extended Data Transfer Width in the Host Control 1 register is used to select 8-bit bus width. As use of 1-bit mode is not intended for shared bus, Data Transfer Width in the Host Control 1 register should be set to 1. - D24 = Bus width preset for Device 1 - D25 = Bus width preset for Device 2 - D26 = Bus width preset for Device 3 - D27 = Bus width preset for Device 4 - D28 = Bus width preset for Device 5 - D29 = Bus width preset for Device 6 - D30 = Bus width preset for Device 7 The function of each bit is defined as follows: 0 = 4 bit buswidth mode 1 = 8 bit buswidth mode
7:6	0b RO	RSVD4: Reserved

Bit Range	Default & Access	Field Name (ID): Description
5:4	0h RO	Number of Interrupt Pins (num_int_pin): This field indicates support of interrupt input pins for shared bus system. Three asynchronous interrupt pins are defined, INT_A#, INT_B# and INT_C#. Which interrupt pin is used is determined by the system. Each one is driven by open drain and then wired OR connection is possible. 00b = Interrupt Input Pin is not supported 01b = INTA is Supported 10b = INTA and INTB are supported 11b = INTA, INTB and INTC are supported
3	0b RO	RSVD5: Reserved
2:0	0h RO	Number of Clock Pins (num_clk_pin): This field indicates support of clock pins to select one of devices for shared bus system. Up to 7 clock pins can be supported. Shared bus is supported by specific system. Then the Standard Host Driver does not support control of these clock pins. 000b Shared bus is not supported 001b 1 SDCLK pin is supported 010b 2 SDCLK pins are supported ... 111b 7 SDCLK pins are supported

16.6.37 SPI Interrupt Support Register (SPI_INT_SUP)—Offset F0h

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + F0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:17, F:0] + 10h

Default: 00h

7	4	0
0	0	0
spi_int_support		

Bit Range	Default & Access	Field Name (ID): Description
7:0	00h RW	SPI Interrupt Support (spi_int_support): This bit is set to indicate the assertion of interrupts in the SPI mode at any time, irrespective of the status of the card select (CS) line. If this bit is zero, then SDIO card can only assert the interrupt line in the SPI mode when the CS line is asserted.

16.6.38 Slot Interrupt Status Register (SLOT_INT_STAT)—Offset FCh

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + FCh

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:17, F:0] + 10h

Default: 0000h

Bit Range	Default & Access	Field Name (ID): Description
15:8	00h RO	Reserved (reserved): Reserved.
7:0	00h RO	Interrupt Signal For Each Slot (int_sig_slot): These status bits indicate the logical OR of Interrupt Signal and Wakeup Signal for each slot. A maximum of 8 slots can be defined. If one interrupt signal is associated with multiple slots, the Host Driver can know which interrupt is generated by reading these status bits. By a power on reset or by setting Software Reset For All, the interrupt signal shall be de-asserted and this status shall read 00h. • Bit 00 = Slot 1 • Bit 01 = Slot 2 • Bit 02 = Slot 3 • • Bit 07 = Slot 8

16.6.39 Host Controller Version Register (HOST_CTRL_VER)—Offset FEh

Type: Memory Mapped I/O Register
(Size: 16 bits)

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:17, F:0] + 10h

15	12	8	4	0
1	0	1	1	0
0	1	0	1	0
0	0	0	0	0
0	0	1	0	0
vend_ver_num				spec_ver_num

Bit Range	Default & Access	Field Name (ID): Description
15:8	b5h RO	Vendor Version Number (vend_ver_num): This status is reserved for the vendor version number. The Host Driver should not use this status.
7:0	02h RO	Specification Version Number (spec_ver_num): This status indicates the Host Controller Spec. Version. The upper and lower 4-bits indicate the version. • 00h = SD Host Specification Version 1.00 • 01h = SD Host Specification Version 2.00, Including the feature of the ADMA and Test Register • 02h = SD Host Specification Version 3.00 • others = Reserved

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Device ID (DEVICEID): Device ID identifies the particular AHB device. This is tied to a strap at the top level.
15:0	0000h RO	Vendor ID (VENDORID): Vendor ID is a unique ID provided by PCI SIG which identifies the manufacturer of the device. This is tied to a strap at the top level.

16.7.2 Status and Command Register (STATUSCOMMAND)—Offset 4h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:18, F:0] + 4h

Default: 00100000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
Reserved0	RMA	RCA	Reserved1	CAPLIST	INTR_STATUS	Reserved2	Reserved3	INTR_DISABLE
								Reserved4
								SERR_ENABLE
								Reserved5
								BME
								MSE
								Reserved6

Bit Range	Default & Access	Field Name (ID): Description
31:30	0h RO	Reserved0: Reserved.
29	0h RW/1C	Received Master Abort (RMA): If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a '1' to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port
28	0h RW/1C	Received Target Abort (RCA): If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port
27:21	00h RO	Reserved1: Reserved.
20	1h RO	Capabilities List (CAPLIST): Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required then this bit should be tied to 0.
19	0h RO	Interrupt Status (INTR_STATUS): This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device's/function's INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.
18:16	0h RO	Reserved2: Reserved.
15:11	00h RO	Reserved3: Reserved.
10	0h RW	Interrupt Disable (INTR_DISABLE): Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt; i.e., Bridge does not send Interrupt Assert message through the IOSF SideBand Channel. Reset value of this bit is 0.
9	0h RO	Reserved4: Reserved.

Bit Range	Default & Access	Field Name (ID): Description
8	0h RW	SERR# Enable (SERR_ENABLE): This bit controls the sending of DO_SERR messages on IOSF SB.
7:3	00h RO	Reserved5: Reserved.
2	0h RW	Bus Master Enable (BME): If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master. Reset value of this bit is 0.
1	0h RW	Memory Space Enable (MSE): This bit controls Bridges response to downstream memory accesses. When set, accesses to the memory space of the device are enabled. Reset value of this bit is 0.
0	0h RO	Reserved6: Reserved.

16.7.3 Revision ID and Class Code Register (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:18, F:0] + 8h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CLASS_CODES							RID	

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES): This register is read-only and is used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Identifies the revision of a particular AHB device. This is tied to a strap at the top level.

16.7.4 Cache Line Size, Latency Timer, and Header Type Register (CLLATHEADERBIST)—Offset Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:18, F:0] + Ch

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
Reserved0	MULFNDEV	HEADERTYPE	LATTIMER	CACHELINE_SIZE				

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Reserved0: Reserved.
23	0h RO	Multifunction Device (MULFNDEV): This bit is always 0 for non-fabric ports. For fabric ports it is driven from the fabric_mult_function strap. A value of 1 indicates a multifunction device; a value of 0 indicates a single function device.
22:16	00h RO	Header Type (HEADERTYPE): Implements Type 0 Configuration header.
15:8	00h RO	Latency Timer (LATTIMER): Doesnt apply to PCI Express. Hardwired to 00h.
7:0	00h RW	Cache Line Size (CACHELINE_SIZE): Doesnt apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected.

16.7.5 Base Address Register (BAR)—Offset 10h

Each AHB device is a single function device with only a single BAR associated with it. Bits 31:4 indicate the Base Address register. Power-up software can determine how much address space the AHB Device requires by writing a value of all 1's to the register and then reading the value back. Bridge will return 0's in all don't-care address bits, effectively specifying the address space required. Unimplemented Base Address registers are hardwired to zero. This is the Size Indicator Read only bits of the register.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:18, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
BASEADDR	SIZEINDICATOR	PREFETCHABLE	TYPE	MESSAGE_SPACE				

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address (BASEADDR): Base address of the AHB device memory space. Taken from Strap values as 1s.

Type: PCI Configuration Register
(Size: 32 bits)

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
SUBSYSTEMID					SUBSYSTEMVENDORID			

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	Subsystem ID (SUBSYSTEMID): This register should be implemented for any function that could be instantiated more than once in a given system. Th is register makes it possible for the operating environment to distinguish one audio subsystem from the other. This is a Read Write Once register.
15:0	0000h RW/O	Subsystem Vendor ID (SUBSYSTEMVENDORID): This register should be implemented for any function that could be instantiated more than once in a given system. This register enables the operating environment to distinguish one subsystem from the other. This is a Read Write Once register.

16.7.8 Expansion ROM Base Address Register (EXPANSION_ROM_BASEADDR)—Offset 30h

Type: PCI Configuration Register
(Size: 32 bits) **Offset:** [B:0, D:18, F:0] + 30h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
EXPANSTON_ROM_BASE								

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	Expansion ROM Base Address (EXPANSION_ROM_BASE): Value of all 0s indicates no support for Expansion ROM.

16.7.9 Capabilities Pointer Register (CAPABILITYPTR)—Offset 34h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:18, F:0] + 34h

Default: 00000080h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	1	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
Reserved0							CAPPTR_POWER	

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Reserved0: Reserved.
7:0	80h RO	Capabilities Pointer (CAPPTR_POWER): Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. When PM capability is disabled, this register is 00h.

16.7.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:18, F:0] + 3Ch

Default: 00000100h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	1	0
0	0	0	0	0	0	0	0	0
MAX_LAT				MIN_GNT				INTLINE
				Reserved0				INTPIN

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Max_Lat (MAX_LAT): Value of 0 indicates that the device has no major requirements for the settings of latency timers.
23:16	00h RO	Min_Gnt (MIN_GNT): Value of 0 indicates that the device has no major requirements for the settings of latency timers.
15:12	0h RO	Reserved0: Reserved.
11:8	1h RO	Interrupt Pin (INTPIN): Each AHB IP on Bridge is a single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space.
7:0	00h RW	Interrupt Line (INTLINE): Bridge does not use this field directly. It is used to communicate to software the interrupt line that the interrupt pin is connected to.

16.7.11 Power Management Capability ID Register (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:18, F:0] + 80h

Default: 48030001h

31	28	24	20	16	12	8	4	0
0	1	0	0	1	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	1
PMESUPPORT		Reserved0		VERSION	NXTCAP		POWER_CAP	

Bit Range	Default & Access	Field Name (ID): Description
31:27	09h RO	PME_Support (PMESUPPORT): This 5-bit field indicates the power states in which the function may assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal while in that power state. bit(11) X XXX1b - PME# can be asserted from D0 bit(12) X XX1Xb - PME# can be asserted from D1. Bridge does not support this state. bit(13) X X1XXb - PME# can be asserted from D2. Bridge does not support this state. bit(14) X 1XXXb - PME# can be asserted from D3hot. bit(15) 1 XXXXb - PME# can be asserted from D3cold. Bridge does not support this state. This field is taken from the private configuration space PME_Support XORed with the PME_Support strap.
26:19	00h RO	Reserved0: Reserved.
18:16	3h RO	Version (VERSION): Indicates support for Revision 1.2 of the PCI Power Management Specification.
15:8	00h RO	Next Capability (NXTCAP): Points to the next capability structure. This points to NULL.
7:0	01h RO	Power Management Capability (POWER_CAP): Indicates this is power management capability.

16.7.12 Power Management Control and Status Register (PMECTRLSTATUS)—Offset 84h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:18, F:0] + 84h

Default: 00000008h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
Reserved0				PMESTATUS	Reserved1		PMEEENABLE	Reserved2
								NO_SOFT_RESET
								Reserved3
								POWERSTATE

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Reserved0: Reserved.
15	0h RW/1C	PME Status (PMESTATUS): 0 = Software clears the bit by writing a 1 to it. 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit in this register.
14:9	00h RO	Reserved1: Reserved.
8	0h RW	PME Enable (PMEENABLE): A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0h RO	Reserved2: Reserved.
3	1h RO	No Soft Reset (NO_SOFT_RESET): This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	Reserved3: Reserved.
1:0	0h RW	Power State (POWERSTATE): This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: 00 = D0 state 11 = D3HOT state Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for upstream decode on fabric ports.

16.7.13 General Purpose Read Write Register1 (GEN_REGRW1)—Offset A0h

16.8.1 SDMA System Address / Argument 2 Register (SYS_ADR)—Offset 0h

This register contains the physical system memory address used for DMA transfers or the second argument for the Auto CMD23.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 00000000h

Diagram illustrating the structure of the `sys_adr` field, which is 32 bits wide. The field is divided into eight 4-bit segments, each labeled with a bit number (31, 28, 24, 20, 16, 12, 8, 4) above the corresponding group of four bits. The bits are represented by circles. The label `sys_adr` is positioned vertically below the 16-bit mark.

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RW	SDMA System Address (sys_adr): (1) SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at each boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates a DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the uppermost byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register. (2) Argument 2 This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

16.8.2 Block Size Register (BLK_SIZE)—Offset 4h

This register is used to configure the number of bytes in a data block.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
tx_blk_size_12	boundary	tr_blk_size		

Bit Range	Default & Access	Field Name (ID): Description
15	0b RW	TX_BLK_SIZE_12 (tx_blk_size_12): Transfer Block Size 12th bit. This bit is added to support 4Kb Data block transfer.

Bit Range	Default & Access	Field Name (ID): Description
15:0	0000h RW	Blocks Count For Current Transfer (blk_count): This register is enabled when Block Count Enable in the Transfer Mode register is set to 1, and is valid only for multiple block transfers. The Host Driver shall set this register to a value between 1 and the maximum block count. The HC decrements the block count after each block transfer, and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (i.e., after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored. When saving transfer context as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, the HD shall restore the previously saved block count. • 0000h = Stop Count • 0001h = 1 block • 0002h = 2 blocks • . . . • FFFFh = 65535 blocks

16.8.4 Argument 1 Register (ARGUMENT)—Offset 8h

This register contains the SD Command Argument.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
argument								

Bit Range	Default & Access	Field Name (ID): Description
31:0	0h RW	Command Argument 1 (argument): The SD Command Argument is specified as bit39-8 of Command-Format in the Physical Layer Specification.

16.8.5 Transfer Mode Register (TX_MODE)—Offset Ch

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command which transfers data (Refer to Data Present Select in the Command register), or before issuing a Resume command. The Host Driver shall save the value of this register when the data transfer is suspended (as a result of a Suspend command) and restore it before issuing a Resume command. To prevent data loss, the Host Controller shall implement write protection for this register during data transactions. Writes to this register shall be ignored when the Command Inhibit (DAT) in the Present State register is 1.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
rsvd		boot_en	spi_mode	cmd_comp_ata
		blk_sel	data_tr_dir	auto_cmd_en
			blk_count_en	dma_en

Bit Range	Default & Access	Field Name (ID): Description
15:9	00h RO	Reserved (rsvd): Reserved.
8	0b RW	BOOT_EN (boot_en): To start boot operation for MMC4.3 1 - To start boot mode 0 - Stop the boot read
7	0b RW	SPI_MODE (spi_mode): SPI mode enable bit. 1 - SPI mode 0 - SD mode
6	0b RW	CMD_COMP_ATA (cmd_comp_ata): Command Completion Signal Enable for CE-ATA Device. ???1??? - Device will send command completion Signal ???0??? - Device will not send command completion Signal
5	0b RW	BLK_SEL (blk_sel): Multi / Single Block Select This bit is set when issuing multiple-block transfer commands using DAT line. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Table 2-8) 1 Multiple Block 0 Single Block
4	0b RW	Data Transfer Direction Select (data_tr_dir): This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the SD Host Controller, and it is set to 0 for all other commands. 1 = Read (Card to Host) 0 = Write (Host to Card)
3:2	0b RW	AUTO_CMD_EN (auto_cmd_en): This field determines use of auto command functions 00b - Auto Command Disabled 01b - Auto CMD12 Enable 10b - Auto CMD23 Enable 11b - Reserved
1	0b RW	Block Count Enable (blk_count_en): This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. (Refer to Table 2-8). If ADMA2 data transfer is more than 65535 blocks, this bit shall be set to 0. In this case, data transfer length is designated by Descriptor Table. 1 = Enable 0 = Disable
0	0b RW	DMA Enable (dma_en): This bit enables DMA functionality as described in section 1.4. DMA can be enabled only if it is supported as indicated in the Capabilities register. One of the DMA modes can be selected by DMA Select in the Host Control register. If DMA is not supported, this bit is meaningless and shall always read 0. If this bit is set to 1, a DMA operation shall begin when the Host Driver writes to the upper byte of Command register (00Fh). 1 = DMA Data transfer 0 = No data transfer or Non DMA data transfer

16.8.6 Command Register (CMD)—Offset Eh

The Host Driver shall check the Command Inhibit (DAT) bit and Command Inhibit (CMD) bit in the Present State register before writing to this register. Writing to the upper byte of this register triggers SD command generation. The Host Driver has the responsibility to write this register because the Host Controller does not protect for writing when Command Inhibit (CMD) is set.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + Eh

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
rsvd	cmd_index	cmd_type	data_pr_sel	cmd_index_chk_en
			cmd_crc_chk_en	reserved
				resp_type_sel

Bit Range	Default & Access	Field Name (ID): Description
15:14	0h RO	Rsvd (rsvd): Reserved.
13:8	0h RW	Command Index (cmd_index): These bits shall be set to the command number (CMD0-63, ACMD0-63) that is specified in bits 45-40 of the Command-Format in the Physical Layer Specification and SDIO Card Specification.
7:6	00b RW	Command Type (cmd_type): There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. (1) Suspend Command If the Suspend command succeeds, the Host Controller shall assume the SD Bus has been released and that it is possible to issue the next command, which uses the DAT line. The Host Controller shall de-assert Read Wait for read transactions and stop checking busy for write transactions. The interrupt cycle shall start, in 4-bit mode. If the Suspend command fails, the Host Controller shall maintain its current state, and the Host Driver shall restart the transfer by setting Continue Request in the Block Gap Control register. (Refer to 3.12.1 Suspend Sequence). (2) Resume Command The Host Driver re-starts the data transfer by restoring the registers in the range of 000-00Dh. (Refer to Figure 1-4 in section 1.6 for the register map.) The Host Controller shall check for busy before starting write transfers. (3) Abort Command If this command is set when executing a read transfer, the Host Controller shall stop reads to the buffer. If this command is set when executing a write transfer, the Host Controller shall stop driving the DAT line. After issuing the Abort command, the Host Driver should issue a software reset. (Refer to 3.8 Abort Transaction). 11b = Abort -- CMD12, CMD52 for writing 'I/O Abort' in CCCR 10b = Resume -- CMD52 for writing 'Function Select' in CCCR 01b = Suspend -- CMD52 for writing 'Bus Suspend' in CCCR 00b = Normal -- Other commands
5	0b RW	Data Present Select (data_pr_sel): This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following: (1) Commands using only CMD line (ex. CMD52). (2) Commands with no data transfer but using busy signal on DAT[0] line (R1b or R5b ex. CMD38). (3) Resume command. 1 = Data Present 0 = No Data Present

Bit Range	Default & Access	Field Name (ID): Description
4	0b RW	Command Index Check Enable (cmd_index_chk_en): If this bit is set to 1, the Host Controller shall check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked. 1 = Enable 0 = Disable
3	0b RW	Command CRC Check Enable (cmd_crc_chk_en): If this bit is set to 1, the Host Controller shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The position of CRC field is determined according to the length of the response. (Refer to definition in D01-00 and Table 2-10 below.) 1 = Enable 0 = Disable
2	0b RO	Reserved (reserved): Reserved.
1:0	0h RW	Response Type Select (resp_type_sel): 00 = No Response 01 = Response Length 136 10 = Response Length 48 11 = Response Length 48 check Busy after response

16.8.7 Response Register 0 (RESPONSE0)—Offset 10h

This register is used to store responses from SD cards.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

cmd_resp

Bit Range	Default & Access	Field Name (ID): Description
31:0	0h RO	Command Response (cmd_resp): The Table 2-12 describes the mapping of command responses from the SD Bus to this register for each response type. In the table, R[] refers to a bit range within the response data as transmitted on the SD Bus, REP[] refers to a bit range within the Response register

16.8.11 Buffer Data Port Register (BUF_DATA_PORT)—Offset 20h

32-bit data port register to access internal buffer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 20h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 00000000h

buf_data

Bit Range	Default & Access	Field Name (ID): Description
31:0	0h RW	Buffer Data (buf_data): The Host Controller buffer can be accessed through this 32-bit Data Port register. Refer to section 1.7.

Bit Range	Default & Access	Field Name (ID): Description
16	1b RO	Card Inserted (crd_ins): This bit indicates whether a card has been inserted. The Host Controller shall debounce this signal so that the Host Driver will not need to wait for it to stabilize. Changing from 0 to 1 generates a Card Insertion interrupt in the Normal Interrupt Status register and changing from 1 to 0 generates a Card Removal interrupt in the Normal Interrupt Status register. The Software Reset For All in the Software Reset register shall not affect this bit. If a card is removed while its power is on and its clock is oscillating, the Host Controller shall clear SD Bus Power in the Power Control register (Refer to Section 2.2.11) and SD Clock Enable in the Clock Control register (Refer to Section 2.2.14). When this bit is changed from 1 to 0, the Host Controller shall immediately stop driving CMD and DAT[3:0] (tri-state). In addition, the Host Driver should clear the Host Controller by the Software Reset For All in Software Reset register. The card detect is active regardless of the SD Bus Power. 1 = Card Inserted 0 = Reset or Debouncing or No Card
15:12	0h RO	Reserved1 (reserved1): Reserved.
11	0b RO	Buffer Read Enable (buf_rd_en): This status is used for non-DMA read transfers. The Host Controller may implement multiple buffers to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is 1, readable data exists in the buffer. A change of this bit from 1 to 0 occurs when all the block data is read from the buffer. A change of this bit from 0 to 1 occurs when block data is ready in the buffer and generates the Buffer Read Ready interrupt. 1 = Read enable 0 = Read disable
10	0b RO	Buffer Write Enable (buf_wr_en): This status is used for non-DMA write transfers. The Host Controller can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, data can be written to the buffer. A change of this bit from 1 to 0 occurs when all the block data is written to the buffer. A change of this bit from 0 to 1 occurs when top of block data can be written to the buffer and generates the Buffer Write Ready interrupt. The Host Controller should neither set Buffer Write Enable nor generate Buffer Write Ready Interrupt after the last block data is written to the Buffer Data Port Register. 1 = Write enable 0 = Write disable
9	0b RO	Read Transfer Active (rd_tx_active): This status is used for detecting completion of a read transfer. Refer to Section 3.12.3 for sequence details. This bit is set to 1 for either of the following conditions: - After the end bit of the read command. - When read operation is restarted by writing a 1 to Continue Request in the Block Gap Control register. This bit is cleared to 0 for either of the following conditions: - When the last data block as specified by block length is transferred to the System. - In case of ADMA2, end of read operation is designated by Descriptor Table. - When all valid data blocks in the Host Controller have been transferred to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1. A Transfer Complete interrupt is generated when this bit changes to 0. 1 = Transferring data 0 = No valid data

Bit Range	Default & Access	Field Name (ID): Description
8	0b RO	Write Transfer Active (wr_tx_active): This status indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the Host Controller. Refer to Section 3.12.4 for more details on the sequence of events. This bit is set in either of the following cases: - After the end bit of the write command. - When write operation is restarted by writing a 1 to Continue Request in the Block Gap Control register. This bit is cleared in either of the following cases: - After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) In case of ADMA2, transfer count is designated by Descriptor Table. - After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request. During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as the result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining non DAT line commands can be issued during write busy. 1 Transferring data 0 No valid data
7:3	00h RO	Reserved (reserved): Reserved.
2	0b RO	DAT Line Active (dat_ln_active): This bit indicates whether one of the DAT lines on SD Bus is in use. (a) In the case of read transactions This status indicates whether a read transfer is executing on the SD Bus. Changing this value from 1 to 0 generates a Block Gap Event interrupt in the Normal Interrupt Status register, as the result of the Stop At Block Gap Request being set. Refer to Section 3.12.3 for details on timing. This bit shall be set in either of the following cases: - After the end bit of the read command. - When writing a 1 to Continue Request in the Block Gap Control register to restart a read transfer. This bit shall be cleared in either of the following cases: - When the end bit of the last data block is sent from the SD Bus to the Host Controller. In case of ADMA2, the last block is designated by the last transfer of Descriptor Table. - When a read transfer is stopped at the block gap initiated by a Stop At Block Gap Request. The Host Controller shall stop read operation at the start of the interrupt cycle of the next block gap by driving Read Wait or stopping SD clock. If the Read Wait signal is already driven (due to data buffer cannot receive data), the Host Controller can continue to stop read operation by driving the Read Wait signal. It is necessary to support Read Wait in order to use suspend / resume function. (b) In the case of write transactions This status indicates that a write transfer is executing on the SD Bus. Changing this value from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register. Refer to Section 3.12.4 for sequence details. This bit shall be set in either of the following cases: - After the end bit of the write command. - When writing to 1 to Continue Request in the Block Gap Control register to continue a write transfer. This bit shall be cleared in either of the following cases: - When the SD card releases write busy of the last data block. If SD card does not drive busy signal for 8 SD Clocks, the Host Controller shall consider the card drive 'Not Busy'. In case of ADMA2, the last block is designated by the last transfer of Descriptor Table. - When the SD card releases write busy prior to waiting for write transfer as a result of a Stop At Block Gap Request. (c) Command with busy This status indicates whether a command indicates busy (ex. erase command for memory) is executing on the SD Bus. This bit is set after the end bit of the command with busy and cleared when busy is de-asserted. Changing this bit from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register. Refer Figure 2-11 to Figure 2-13. 1 = DAT Line Active 0 = DAT Line Inactive

Bit Range	Default & Access	Field Name (ID): Description
1	0b RO	Command Inhibit (DAT) (cmd_inhibit_dat): This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates the Host Controller can issue the next SD Command. Commands with busy signal belong to Command Inhibit (DAT) (ex. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Normal Interrupt Status register. Note: The SD Host Driver can save registers in the range of 000-00Dh for a suspend transaction after this bit has changed from 1 to 0. 1 Cannot issue command which uses the DAT line 0 Can issue command which uses the DAT line
0	0b RO	Command Inhibit (CMD) (cmd_inhibit_cmd): Command Inhibit (CMD) If this bit is 0, it indicates the CMD line is not in use and the Host Controller can issue a SD Command using the CMD line. cleared when the command response is received. Auto CMD12 and Auto CMD23 consist of two responses. In this case, this bit is not cleared by the response of CMD12 or CMD23 but cleared by the response of a read/write command. Status issuing Auto CMD12 is not read from this bit. So if a command is issued during Auto CMD12 operation, Host Controller shall manage to issue two commands: CMD12 and a command set by Command register. Even if the Command Inhibit (DAT) is set to 1, commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete Interrupt in the Normal Interrupt Status register. If the Host Controller cannot issue the command because of a command conflict error (Refer to Command CRC Error in Section 2.2.18) or because of Command Not Issued By Auto CMD12 Error (Refer to Section 2.2.23), this bit shall remain 1 and the Command Complete is not set. 1 Cannot issue command 0 Can issue command using only CMD line

16.8.13 Host Control 1 Register (HOST_CTL)—Offset 28h

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 28h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 00h

7			4				0
0	0	0	0	0	0	0	0
crd_det_sig_sel	crd_det_tst_lv	sd8_bit_mode	dma_sel	hi_spd_en	data_tx_wid	led_ctl	

Bit Range	Default & Access	Field Name (ID): Description
7	0b RW	Card Detect Signal Selection (crd_det_sig_sel): This bit selects source for the card detection. 1 = The Card Detect Test Level is selected (for test purposes) 0 = SD CD# is selected (for normal use) When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during the period of debouncing.

Bit Range	Default & Access	Field Name (ID): Description
6	0b RW	Card Detect Test Level (crd_det_tst_lvl): This bit is enabled while the Card Detect Signal Selection is set to 1, and it indicates whether or not the card is inserted. 1 = Card Inserted 0 = No Card
5	0b RW	SD8 Bit Mode (sd8_bit_mode): This bit selects the data width of the HC. The HD shall select it to match the data width of the SD card.
4:3	00b RW	DMA Select (dma_sel): One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. 00 = SDMA is selected 01 = Reserved (New assignment is not allowed) 10 = 32-bit Address ADMA2 is selected 11 = Reserved (will be modified by Version 4.00)
2	0b RW	High Speed Enable (hi_spd_en): This bit is optional. Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is set to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock (up to 25MHz). If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock (up to 50MHz). If Preset Value Enable in the Host Control 2 register is set to 1, Host Driver needs to reset SD Clock Enable before changing this field to avoid generating clock glitches. After setting this field, the Host Driver sets SD Clock Enable again. 1 = 4-bit mode 0 = 1-bit mode
1	0b RW	Data Transfer Width (data_tx_wid): Reserved.
0	0b RW	LED Control (led_ctl): This bit selects the data width of the Host Controller. The Host Driver shall set it to match the data width of the SD card. 1 = 4-bit mode 0 = 1-bit mode

16.8.14 Power Control Register (PWR_CTL)—Offset 29h

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 29h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 00h

7	4	0

rsvd	hw_rst	sd_bus_pwr
		sd_bus_volt_sel

Bit Range	Default & Access	Field Name (ID): Description
7:5	0h RO	Rsvd (rsvd): Reserved.

Bit Range	Default & Access	Field Name (ID): Description
4	0b RW	HW Reset (hw_rst): Reserved.
3:1	0h RW	SD Bus Voltage Select (sd_bus_volt_sel): By setting these bits, the Host Driver selects the voltage level for the SD card. Before setting this register, the Host Driver shall check the Voltage Support bits in the Capabilities register. If an unsupported voltage is selected, the Host System shall not supply SD Bus voltage. 111b = 3.3V (Typ.) 110b = 3.0V (Typ.) 101b = 1.8V (Typ.) 100b 000b Reserved
0	0b RW	SD Bus Power (sd_bus_pwr): Before setting this bit, the SD Host Driver shall set SD Bus Voltage Select. If the Host Controller detects the No Card state, this bit shall be cleared. If this bit is cleared, the Host Controller shall immediately stop driving CMD and DAT[3:0] (tri-state) and drive SDCLK to low level (Refer to Section 2.2.14) For SD Controller, this bit controls the bus voltage to SDMMC3. For SDIO Controller, power to SDIO device on SDMMC2 is not controlled by this bit. GPIO register and pin can be used to controller the SDIO device power. For eMMC Controller, power to eMMC device on SDMMC1 is not controlled by this bit. GPIO register and pin or alternative solutions can be used. 1 = Power on 0 = Power off

16.8.15 Block Gap Control Register (_BLK_GAP_CTL)—Offset 2Ah

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 2Ah

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 00h

7	4	0
0	0	0
rsvd	drive_ccsd	int_blk_gap
		rd_wait_ctl
		cont_req
		stp_blk_gap_req

Bit Range	Default & Access	Field Name (ID): Description
7:5	0h RO	Reserved (rsvd): Reserved.
4	0b RW	DRIVE_CCSD (drive_ccsd): If the driver set this bit (change from ???0??? to ???1???), Host controller will send command completion.

Bit Range	Default & Access	Field Name (ID): Description
3	0b RW	Interrupt at Block Gap (int_blk_gap): This bit is valid only in 4-bit mode of the SDIO card and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SD card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card. 1 = Enabled 0 = Disabled
2	0b RW	Read Wait Control (rd_wait_ctl): The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise, the Host Controller has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card. If the card does not support read wait, this bit shall never be set to 1, otherwise DAT line conflict may occur. If this bit is set to 0, Suspend/Resume cannot be supported. 1 = Enable Read Wait Control 0 = Disable Read Wait Control
1	0b RW	Continue Request (cont_req): This bit is used to restart a transaction, which was stopped using the Stop At Block Gap Request. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit 1 to restart the transfer. The Host Controller automatically clears this bit in either of the following cases: - In the case of a read transaction, the DAT Line Active changes from 0 to 1 as a read transaction restarts. - In the case of a write transaction, the Write Transfer Active changes from 0 to 1 as the write transaction restarts. Therefore, it is not necessary for Host Driver to set this bit to 0. If Stop At Block Gap Request is set to 1, any write to this bit is ignored. 1 = Restart 0 = Not affect
0	0b RW	Stop at Block Gap Request (stp_blk_gap_req): This bit is used to stop executing read and write transaction at the next block gap for non-DMA, SDMA and ADMA transfers. The Host Driver shall leave this bit set Copyright 2002-2011 SD Association SD Host Controller Simplified Specification Version 3.00 44 to 1 until the Transfer Complete is set to 1. Clearing both Stop At Block Gap Request and Continue Request shall not cause the transaction to restart. When Host Controller version is 1.00, the Host Driver can set this bit if the card supports Read Wait Control. When Host Controller version is 2.00 or later, the Host Driver can set this bit regardless of the card supports Read Wait Control. The Host Controller shall stop read transfer by using Read Wait or stopping SD clock. In case of write transfers in which the Host Driver writes data to the Buffer Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to Buffer Data Port register. This bit affects Read Transfer Active, Write Transfer Active, DAT Line Active and Command Inhibit (DAT) in the Present State register. Regarding detailed control of bits D01 and D00, refer to Section 3.8 and 3.12. 1 = Stop 0 = Transfer

16.8.16 Wakeup Control Register (WAKEUP_CTL)—Offset 2Bh

This register is mandatory for the Host Controller, but wakeup functionality depends on the Host Controller system hardware and software. The Host Driver shall maintain voltage on the SD Bus, by setting SD Bus Power to 1 in the Power Control register, when wakeup event via Card Interrupt is desired. Wakeup Event is not supported by Host Controller. Sideband wake via GPIO pin and register shall be used instead. During RTD3, GPIO register is readable and GPIO signal is routed to APIC.

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 2Bh

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

0	0	0	0	0
sdclk_freq_sel				upper_sdclk_freq_sel
				rsvd
				sd_clk_en
				int_clk_stable
				int_clk_en

Bit Range	Default & Access	Field Name (ID): Description
15:8	00h RW	SDCLK Frequency Select (sdclk_freq_sel): This register is used to select the frequency of the SDCLK pin. The definition of this field is dependent on the Host Controller Version. (1) 8-bit Divided Clock Mode This mode is supported by the Host Controller Version 1.00 and 2.00. The frequency is not programmed directly, rather, this register holds the divisor of the Base Clock Frequency For SD Clock in the capabilities register. Only the following settings are allowed. (1) 8-bit Divided Clock Mode • 80h = base clock divided by 256 • 40h = base clock divided by 128 • 20h = base clock divided by 64 • 10h = base clock divided by 32 • 08h = base clock divided by 16 • 04h = base clock divided by 8 • 02h = base clock divided by 4 • 01h = base clock divided by 2 • 00h = base clock(10MHz and up) Setting 00h specifies the highest frequency of the SD Clock. When setting multiple bits, the most significant bit is used as the divisor, but it should not be set. The three default divider values can be calculated by the frequency that is defined by the Base Clock Frequency For SD Clock in the Capabilities register. • 400KHz divider value • 25MHz divider value • 50MHz divider value According to the Physical Layer Specification, the maximum SD Clock frequency is 25 MHz in normal speed mode and 50MHz in high speed mode, and shall never exceed this limit. The frequency of the SDCLK is set by the following formula: Clock Frequency = (Base Clock) / divisor Thus, choose the smallest possible divisor which results in a clock frequency that is less than or equal to the target frequency. For example, if the Base Clock Frequency For SD Clock in the Capabilities register has the value 33MHz, and the target frequency is 25MHz, then choosing the divisor value of 01h will yield 16.5MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400KHz, the divisor value of 40h yields the optimal clock value of 258KHz. (2) 10-bit Divided Clock Mode Host Controller Version 3.00 supports this mandatory mode instead of the 8-bit Divided Clock Mode. The length of divider is extended to 10 bits, and all divider values shall be supported. • 3FFh = 1/2046 Divided Clock • N = 1/2N Divided Clock (Duty 50%) • 002h = 1/4 Divided Clock • 001h = 1/2 Divided Clock • 000h = Base Clock (10MHz and up) • 3FFh = Base Clock * M / 1024 • = Base Clock * M / N • N - 1 = Base Clock * M / N • = Base Clock * M / 3 • 002h = Base Clock * M / 3 • 001h = Base Clock * M / 2 • 000h = Base Clock * M This field depends on setting of Preset Value Enable in the Host Control 2 register. If Preset Value Enable = 0, this field is set by Host Driver. If the Preset Value Enable = 1, this field is automatically set to a value specified in one of Preset Value registers.

Bit Range	Default & Access	Field Name (ID): Description
7:6	0h RO	Upper Bits of SDCLK Frequency Select (upper_sdclk_freq_sel): Host Controller Versions 1.00 and 2.00 do not support these bits and they are treated as 00b fixed value (ROC). Host Controller Version 3.00 shall support these bits to expand SDCLK Frequency Select to 10-bit. Bit 07-06 is assigned to bit 09-08 of clock divider in SDCLK Frequency Select.
5:3	0h RO	Rsvd (rsvd): Reserved.
2	0b RW	SD Clock Enable (sd_clk_en): The Host Controller shall stop SDCLK when writing this bit to 0. SDCLK Frequency Select can be changed when this bit is 0. Then, the Host Controller shall maintain the same clock frequency until SDCLK is stopped (Stop at SDCLK=0). If the Card Inserted in the Present State register is cleared, this bit shall be cleared. 1 = Enable 0 = Disable
1	0b RO	Internal Clock Stable (int_clk_stable): This bit is set to 1 when SD clock is stable after writing to Internal Clock Enable in this register to 1. The SD Host Driver shall wait to set SD Clock Enable until this bit is set to 1. Note: This is useful when using PLL for a clock oscillator that requires setup time. 1 = Ready 0 = Not Ready
0	0b RW	Internal Clock Enable (int_clk_en): This bit is set to 0 when the Host Driver is not using the Host Controller, or when the Host Controller awaits a wakeup event. The Host Controller should stop its internal clock to go to a very low power state. Still, registers shall be able to be read and written. Clock starts to oscillate when this bit is set to 1. When clock oscillation is stable, the Host Controller shall set Internal Clock Stable in this register to 1. This bit shall not affect card detection. 1 = Oscillate 0 = Stop

16.8.18 Timeout Control Register (TIMEOUT_CTL)—Offset 2Eh

At the initialization of the Host Controller, the Host Driver shall set the Data Timeout Counter Value according to the Capabilities register.

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 2Eh

rsvd				sw_rst_dat_in		sw_rst_cmd_in	sw_rst_all

Bit Range	Default & Access	Field Name (ID): Description
7:3	0h RO	Reserved (rsvd): Reserved.

Bit Range	Default & Access	Field Name (ID): Description
2	0b RW	Software Reset For DAT Line (sw_rst_dat_in): Only part of data circuit is reset. DMA circuit is also reset. The following registers and bits are cleared by this bit: Buffer Data Port register • Buffer is cleared and initialized. Present State register • Buffer Read Enable • Buffer Write Enable • Read Transfer Active • Write Transfer Active • DAT Line Active • Command Inhibit (DAT) Block Gap Control register • Continue Request • Stop At Block Gap Request Normal Interrupt Status register • Buffer Read Ready • Buffer Write Ready • DMA Interrupt • Block Gap Event • Transfer Complete • 1 = Reset • 0 = Work When Auto or Dynamic Clock Gating is enabled for this controller, the Software Reset bit may require several reads before the bit clears.
1	0b RW	Software Reset For CMD Line (sw_rst_cmd_in): Only part of command circuit is reset. The following registers and bits are cleared by this bit: Present State register • Command Inhibit (CMD) Normal Interrupt Status register • Command Complete • 1 = Reset • 0 = Work When Auto or Dynamic Clock Gating is enabled for this controller, the Software Reset bit may require several reads before the bit clears.
0	0b RW	Software Reset For All (sw_rst_all): This reset affects the entire Host Controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared to 0. During its initialization, the Host Driver shall set this bit to 1 to reset the Host Controller. The Host Controller shall reset this bit to 0 when Capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All may not affect the value of the Capabilities registers. If this bit is set to 1, the host driver should issue reset command and reinitialize the SD card. • 1 = Reset • 0 = Work When Auto or Dynamic Clock Gating is enabled for this controller, the Software Reset bit may require several reads before the bit clears.

16.8.20 Normal Interrupt Status Register (NML_INT_STATUS)—Offset 30h

The Normal Interrupt Status Enable affects reads of this register, but Normal Interrupt Signal Enable does not affect these reads. An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. Writing 1 to a bit of RW1C attribute clears it; writing 0 keeps the bit unchanged. Writing 1 to a bit of ROC attribute keeps the bit unchanged. More than one status can be cleared with a single register write. The Card Interrupt is cleared when the card stops asserting the interrupt; that is, when the Card Driver services the interrupt condition.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + 30h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 0000h

15			12				8				4				0
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
err_int	boot_ter_int	boot_ck_rcv	re_tune	int_c	int_b	int_a	crd_int	crd_rm	crd_ins	buf_rd_rdy	buf_wr_rdy	dma_int	blk_gap_event	tx_comp	cmd_comp

Bit Range	Default & Access	Field Name (ID): Description
15	0b RO	Error Interrupt (err_int): If any of the bits in the Error Interrupt Status register are set, then this bit is set. Therefore the Host Driver can efficiently test for an error by checking this bit first. This bit is read only. 1 = Error 0 = No Error
14	0b RW/1C	BOOT_TER_INT (boot_ter_int): boot ter int
13	0b RW/1C	BOOT_ACK_RCV (boot_ck_rcv): boot ack rcv
12	0b RO	Re-Tuning Event (re_tune): This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. Host Controller requests Host Driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 1 Re-Tuning should be performed 0 Re-Tuning is not required
11	0b RO	INT_C (int_c): This status is set if INT_C is enabled and INT_C# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_C interrupt factor. Refer to the Shared Bus Control register. 1 = INT_C is detected 0 = No interrupt is detected
10	0b RO	INT_B (int_b): This status is set if INT_B is enabled and INT_B# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_B interrupt factor. Refer to the Shared Bus Control register. 1 = INT_B is detected 0 = No interrupt is detected
9	0b RO	INT_A (int_a): This status is set if INT_A is enabled and INT_A# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_A interrupt factor. Refer to the Shared Bus Control register. 1 = INT_A is detected 0 = No interrupt is detected

Bit Range	Default & Access	Field Name (ID): Description
8	0b RO	Card Interrupt (crd_int): Writing this bit to 1 does not clear this bit. It is cleared by resetting the SD card interrupt factor. In 1-bit mode, the Host Controller shall detect the Card Interrupt without SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so there are some sample delays between the interrupt signal from the SD card and the interrupt to the Host System. When this status has been set and the Host Driver needs to start this interrupt service, Card Interrupt Status Enable in the Normal Interrupt Status Enable register may be set to 0 in order to clear the card interrupt statuses latched in the Host Controller and to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset interrupt factors in the SD card and the interrupt signal may not be asserted), set Card Interrupt Status Enable to 1 and start sampling the interrupt signal again. Interrupt detected by DAT[1] is supported when there is a card per slot. In case of shared bus, interrupt pins are used to detect interrupts. If 000b is set to Interrupt Pin Select in the Shared Bus Control register, this status is effective. Non-zero value is set to Interrupt Pin Select, INT_A, INT_B or INT_C is then used to device interrupts. 1 = Generate Card Interrupt 0 = No Card Interrupt
7	0b RW/1C	Card Removal (crd_rm): This status is set if the Card Inserted in the Present State register changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card detect state may possibly be changed when the Host Driver clear this bit and interrupt event may not be generated. 1 = Card removed 0 = Card state stable or Debouncing
6	0b RW/1C	Card Insertion (crd_ins): This status is set if the Card Inserted in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed, because the card detect state may possibly be changed when the Host Driver clears this bit and interrupt event may not be generated. 1 Card inserted 0 Card state stable or Debouncing
5	0b RW/1C	Buffer Read Ready (buf_rd_rdy): This status is set if the Buffer Read Enable changes from 0 to 1. Refer to the Buffer Read Enable in the Present State register. While performing tuning procedure (Execute Tuning is set to 1), Buffer Read Ready is set to 1 for every CMD19 execution. 1 = Ready to read buffer 0 = Not ready to read buffer
4	0b RW/1C	Buffer Write Ready (buf_wr_rdy): This status is set if the Buffer Write Enable changes from 0 to 1. Refer to the Buffer Write Enable in the Present State register. 1 = Ready to write buffer 0 = Not ready to write buffer
3	0b RW/1C	DMA Interrupt (dma_int): This status is set if the Host Controller detects the Host SDMA Buffer boundary during transfer. Refer to the Host SDMA Buffer Boundary in the Block Size register. Other DMA interrupt factors may be added in the future. In case of ADMA, by setting Int field in the descriptor table, Host Controller generates this interrupt. Suppose that it is used for debugging. This interrupt shall not be generated after the Transfer Complete. 1 = DMA Interrupt is generated 0 = No DMA Interrupt
2	0b RW/1C	Block Gap Event (blk_gap_event): If the Stop At Block Gap Request in the Block Gap Control register is set, this bit is set when both a read / write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1. (1) In the case of a Read Transaction This bit is set at the falling edge of the DAT Line Active Status, when the transaction is stopped at SD Bus timing. The Read Wait shall be supported in order to use this function. Refer to Section 3.12.3 for timing details. p1(1) In the case of a Write Transaction This bit is set at the falling edge of Write Transfer Active Status (after getting CRC status at SD Bus timing). Refer to Section 3.12.4 for more details on the sequence of events. 1 = Transaction stopped at block gap 0 = No Block Gap Event

Bit Range	Default & Access	Field Name (ID): Description
1	0b RW/1C	Transfer Complete (tx_comp): This bit is set when a read / write transfer and a command with busy is completed. (1) In the case of a Read Transaction This bit is set at the falling edge of Read Transfer Active Status. This interrupt is generated in two cases. The first is when a data transfer is completed as specified by data length (After the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request in the Block Gap Control register (After valid data has been read to the Host System). Refer to Section 3.12.3 for more details on the sequence of events. (2) In the case of a Write Transaction This bit is set at the falling edge of the DAT Line Active Status. This interrupt is generated in two cases. The first is when the last data is written to the SD card as specified by data length and the busy signal released. The second is when data transfers are stopped at the block gap by setting Stop At Block Gap Request in the Block Gap Control register and data transfers completed. (After valid data is written to the SD card and the busy signal released). Refer to Section 3.12.4 for more details on the sequence of events. (3) In the case of a command with busy This bit is set when busy is de-asserted. Refer to DAT Line Active and Command Inhibit (DAT) in the Present State register. Refer to the spec for the relationship between Transfer Complete and Data Timeout Error. 1 = Command execution is completed 0 = Not complete While performing tuning procedure (Execute Tuning is set to 1), Transfer Complete is not set to 1.
0	0b RW/1C	Command Complete (cmd_comp): This bit is set when get the end bit of the command response. Auto CMD12 and Auto CMD23 consist of two responses. Command Complete is not generated by the response of CMD12 or CMD23 but generated by the response of a read/write command. Refer to Command Inhibit (CMD) in the Present State register for how to control this bit. Command Timeout Error has higher priority than Command Complete. If both bits are set to 1, it can be considered that the response was not received correctly. For a tabular description of the relationship between these two bits, refer to the description of Command Complete in the spec. 1 = Command complete 0 = No command complete

16.8.21 Error Interrupt Status Register (ERR_INT_STATUS)—Offset 32h

Signals defined in this register can be enabled by the Error Interrupt Status Enable register, but not by the Error Interrupt Signal Enable register. The interrupt is generated when the Error Interrupt Signal Enable is enabled and at least one of the statuses is set to 1. Writing to 1 clears the bit, and writing to 0 keeps the bit unchanged. More than one status can be cleared at the one register write.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + 32h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 0000h

0	0	0	0	0
0	0	0	0	0
0	0	0	0	0
0	0	0	0	0
0	0	0	0	0

Bit Range	Default & Access	Field Name (ID): Description
15	0b RW	Vendor Specific Error Status (vend_spec_err_status): Reserved.
14	0b RW	Boot Command Timeout Error (boot_cmd_timeout_err): Occur if the boot are access command is issued to the agent which has no permission to access the boot area.
13	0b RW	CEATA Error (ceata_err): Occurs when ATA command termination has occured due to an error condition the device has encountered.
12	0b RW	Target Response Error (tgt_rsp_err): Occurs when detecting ERROR in m_hresp(dma transaction).
11:10	0h RO	Reserved (rsvd): Reserved.
9	0b RW	ADMA Error (adma_err): This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. 0 = error 1 = no error
8	0b RW	Auto CMD12 Error (cmd12_err): Auto CMD12 and Auto CMD23 use this error status. This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error Status register has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error. 1 = error 0 = no error
7	0b RW	Current Limit Error (cur_limit_err): By setting the SD Bus Power bit in the Power Control register, the Host Controller is requested to supply power for the SD Bus. If the Host Controller supports the Current Limit function, it can be protected from an illegal card by stopping power supply to the card in which case this bit indicates a failure status. Reading 1 means the Host Controller is not supplying power to SD card due to some failure. Reading 0 means that the Host Controller is supplying power and no error has occurred. The Host Controller may require some sampling time to detect the current limit. If the Host Controller does not support this function, this bit shall always be set to 0. 1 = power fail 0 = no error
6	0b RW	Data End Bit Error (data_end_bit_err): Occurs either when detecting 0 at the end bit position of read data which uses the DAT line or at the end bit position of the CRC Status. 1 = error 0 = no error
5	0b RW	Data CRC Error (data_crc_err): Occurs when detecting CRC error when transferring read data which uses the DAT line or when detecting the Write CRC status having a value of other than 010b.
4	0b RW	Data Timeout Error (data_timeout_err): This bit is set when detecting one of following timeout conditions. - Busy timeout for R1b,R5b type - Busy timeout after Write CRC status - Write CRC Status timeout - Read Data timeout 1 = time out 0 = no error

Bit Range	Default & Access	Field Name (ID): Description
3	0b RW	Command Index Error (cmd_index_err): This bit is set if a Command Index error occurs in the command response. 1 = error 0 = no error
2	0b RW	Command End Bit Error (cmd_end_bit_err): This bit is set when detecting that the end bit of a command response is 0. 1 = End Bit Error generated 0 = no error
1	0b RW	Command CRC Error (cmd_crc_err): Command CRC Error is generated in two cases. If a response is returned and the Command Timeout Error is set to 0 (indicating no timeout), this bit is set to 1 when detecting a CRC error in the command response. The Host Controller detects a CMD line conflict by monitoring the CMD line when a command is issued. If the Host Controller drives the CMD line to 1 level, but detects 0 level on the CMD line at the next SD clock edge, then the Host Controller shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict (refer to tabular data in the spec. that explains the relationship between Command CRC Error and Command Timeout Error). 1 = CRC Error Generated. 0 = no error
0	0b RW	Command Timeout Error (cmd_timeout_err): This bit is set only if no response is returned within 64 SD clock cycles from the end bit of the command. If the Host Controller detects a CMD line conflict (in which case Command CRC Error shall also be set, as shown in tabular data in the spec that explains the relationship between this bit and Command CRC Error) this bit shall be set without waiting for 64 SD clock cycles, because the command will be aborted by the Host Controller. 1 = time out 0 = no Error

16.8.22 Normal Interrupt Status Enable (NRM_INT_STATUS_EN)—Offset 34h

Setting to 1 enables Interrupt Status. **Implementation Note:** The Host Controller may sample the card interrupt signal during interrupt period, and may hold its value in the flip-flop. If the **Card Interrupt Status Enable** is set to 0, the Host Controller shall clear all internal signals regarding Card Interrupt.

Access Method

BAR Reference: [B:0, D:18, F:0] + 10h

Default: 00000000h

[illegible]

Bit Range	Default & Access	Field Name (ID): Description
31	0b RW	Preset Value (preset_value): Host Controller Version 3.00 supports this bit. As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set to automatic This bit enables the functions defined in the Preset Value registers. 1 = Automatic Selection by Preset Value are Enabled 0 SDCLK and Driver Strength are controlled by Host Driver If this bit is set to 0, SDCLK Frequency Select, Clock Generator Select in the Clock Control register and Driver Strength Select in Host Control 2 register are set by Host Driver. If this bit is set to 1, SDCLK Frequency Select, Clock Generator Select in the Clock Control register and Driver Strength Select in Host Control 2 register are set by Host Controller as specified in the Preset Value registers.
30	0b RW	Asynchronous Interrupt (async_int): This bit can be set to 1 if a card support asynchronous interrupt and Asynchronous Interrupt Support is set to 1 in the Capabilities register. Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver Card Interrupt to the host when it is asserted by the Card. Usage: It is recommended that Synchronous Interrupt mode be used for SDIO Controller by setting this be to '0'. If Asynchronous Interrupt Enable mode is used, it is required that this bit remain '0' until SD initialization sequence is complete. 1 = Enabled 0 = Disabled

Bit Range	Default & Access	Field Name (ID): Description
29:24	0b RO	RSVD0: Reserved
23	0b RW	Sampling Clock (sampling_clock): This bit is set by tuning procedure when Execute Tuning is cleared.
22	0b RW/AC	Execute Tuning (execute_tuning): This bit is set to 1 to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to Sampling Clock Select. Tuning procedure is aborted by writing 0. Refer to the spec for more detail about tuning procedure. 1 = Execute Tuning 0 = Not Tuned or Tuning Completed
21:20	0b RW	Driver Strength (driver_strength): Host Controller output driver in 1.8V signaling is selected by this bit.
19	0b RW	Voltage Regulator Control for I/O Cell (vl): This bit controls voltage regulator for I/O cell.

16.8.31 Force Event Register for Error Interrupt Status (FORCE_EVENT_ERR_INT_STAT)—Offset 52h

Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register if the corresponding bit of the Error Interrupt Status Enable Register is set.

- Writing 1 : set each bit of the Error Interrupt Status Register
- Writing 0 : no effect

Note: By setting this register, the Error Interrupt can be set in the Error Interrupt Status register. In order to generate interrupt signal, both the Error Interrupt Status Enable and Error Interrupt Signal Enable shall be set.

Access Method

16.8.32 ADMA Error Status Register (ADMA_ERR_STAT)—Offset 54h

When ADMA Error Interrupt occurs, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. To recover from the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
- ST_CADR: This state is never set because do not generate ADMA error in this state.

- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 54h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:18, F:0] + 10h

								Reserved4
								SERR_ENABLE
								Reserved5
								BME
								MSE
								Reserved6

Bit Range	Default & Access	Field Name (ID): Description
31:30	0h RO	Reserved0: Reserved.
29	0h RW/1C	Received Master Abort (RMA): If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a '1' to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port
28	0h RW/1C	Received Target Abort (RCA): If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port
27:21	00h RO	Reserved1: Reserved.
20	1h RO	Capabilities List (CAPLIST): Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required then this bit should be tied to 0.
19	0h RO	Interrupt Status (INTR_STATUS): This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device's/function's INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.
18:16	0h RO	Reserved2: Reserved.
15:11	00h RO	Reserved3: Reserved.
10	0h RW	Interrupt Disable (INTR_DISABLE): Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt; i.e., Bridge does not send Interrupt Assert message through the IOSF SideBand Channel. Reset value of this bit is 0.
9	0h RO	Reserved4: Reserved.

Bit Range	Default & Access	Field Name (ID): Description
8	0h RW	SERR# Enable (SERR_ENABLE): This bit controls the sending of DO_SERR messages on IOSF SB.
7:3	00h RO	Reserved5: Reserved.
2	0h RW	Bus Master Enable (BME): If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master. Reset value of this bit is 0.
1	0h RW	Memory Space Enable (MSE): This bit controls Bridges response to downstream memory accesses. When set, accesses to the memory space of the device are enabled. Reset value of this bit is 0.
0	0h RO	Reserved6: Reserved.

16.9.3 Revision ID and Class Code Register (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:23, F:0] + 8h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CLASS_CODES							RID	

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES): This register is read-only and is used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Identifies the revision of a particular AHB device. This is tied to a strap at the top level.

16.9.4 Cache Line Size, Latency Timer, and Header Type Register (CLLATHEADERBIST)—Offset Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:23, F:0] + Ch

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
Reserved0	MULFNDEV	HEADERTYPE	LATTIMER	CACHELINE_SIZE				

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Reserved0: Reserved.
23	0h RO	Multifunction Device (MULFNDEV): This bit is always 0 for non-fabric ports. For fabric ports it is driven from the fabric_mult_function strap. A value of 1 indicates a multifunction device; a value of 0 indicates a single function device.
22:16	00h RO	Header Type (HEADERTYPE): Implements Type 0 Configuration header.
15:8	00h RO	Latency Timer (LATTIMER): Doesnt apply to PCI Express. Hardwired to 00h.
7:0	00h RW	Cache Line Size (CACHELINE_SIZE): Doesnt apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected.

16.9.5 Base Address Register (BAR)—Offset 10h

Each AHB device is a single function device with only a single BAR associated with it. Bits 31:4 indicate the Base Address register. Power-up software can determine how much address space the AHB Device requires by writing a value of all 1's to the register and then reading the value back. Bridge will return 0's in all don't-care address bits, effectively specifying the address space required. Unimplemented Base Address registers are hardwired to zero. This is the Size Indicator Read only bits of the register.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:23, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
BASEADDR	SIZEINDICATOR	PREFETCHABLE	TYPE	MESSAGE_SPACE				

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address (BASEADDR): Base address of the AHB device memory space. Taken from Strap values as 1s.

Bit Range	Default & Access	Field Name (ID): Description
11:4	00h RO	Size Indicator (Read Only) (SIZEINDICATOR): Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0s.
3	0h RO	Prefetchable (PREFETCHABLE): Indicates that this bar is not prefetchable.
2:1	0h RO	Type (TYPE): '00' indicates that the BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE): 0 Indicates that this BAR is present in the memory space.

16.9.6 Base Address Register 1 (BAR1)—Offset 14h

Memory accesses to BAR1 region access the PCI configuration space for the LPIO device. BAR1 region is always 4K. However SW accesses through BAR1 should only access the regular PCI configuration space. BAR1 memory accesses which do not access a defined PCI configuration register are treated as accesses to a reserved register.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:23, F:0] + 14h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
BASEADDR1						SIZEINDICATOR1		
						PREFETCHABLE1		
						TYPE1		
						MESSAGE_SPACE1		

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address Register1 (BASEADDR1): This field is present if BAR1 is enabled through private config space. If this register is disabled then this is RO and always returns 0.
11:4	00h RO	Size Indicator1 (SIZEINDICATOR1): Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE1): Indicates that this bar is not prefetchable.
2:1	0h RO	Type (TYPE1): '00' indicates that the BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE1): 0 Indicates that this BAR is present in the memory space.

Offset: [B:0, D:23, F:0] + 2Ch

16.9.8 Expansion ROM Base Address Register (EXPANSION_ROM_BASEADDR)—Offset 30h

Offset: [B:0, D:23, F:0] + 30h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	Expansion ROM Base Address (EXPANSION_ROM_BASE): Value of all 0s indicates no support for Expansion ROM.

16.9.9 Capabilities Pointer Register (CAPABILITYPTR)—Offset 34h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:23, F:0] + 34h

Default: 00000080h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	1	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
Reserved0							CAPPTR_POWER	

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Reserved0: Reserved.
7:0	80h RO	Capabilities Pointer (CAPPTR_POWER): Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. When PM capability is disabled, this register is 00h.

16.9.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:23, F:0] + 3Ch

Default: 00000100h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	1	0
0	0	0	0	0	0	0	0	0
MAX_LAT				MIN_GNT				INTLINE

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Max_Lat (MAX_LAT): Value of 0 indicates that the device has no major requirements for the settings of latency timers.
23:16	00h RO	Min_Gnt (MIN_GNT): Value of 0 indicates that the device has no major requirements for the settings of latency timers.
15:12	0h RO	Reserved0: Reserved.
11:8	1h RO	Interrupt Pin (INTPIN): Each AHB IP on Bridge is a single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space.
7:0	00h RW	Interrupt Line (INTLINE): Bridge does not use this field directly. It is used to communicate to software the interrupt line that the interrupt pin is connected to.

16.9.11 Power Management Capability ID Register (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:23, F:0] + 80h

Default: 48030001h

31	28	24	20	16	12	8	4	0
0	1	0	0	1	0	0	0	0
0	0	0	0	0	0	0	0	1
PMESUPPORT	Reserved0	VERSION	NXTCAP	POWER_CAP				

Bit Range	Default & Access	Field Name (ID): Description
31:27	09h RO	PME_Support (PMESUPPORT): This 5-bit field indicates the power states in which the function may assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal while in that power state. bit(11) X XXX1b - PME# can be asserted from D0 bit(12) X XX1Xb - PME# can be asserted from D1. Bridge does not support this state. bit(13) X X1XXb - PME# can be asserted from D2. Bridge does not support this state. bit(14) X 1XXXb - PME# can be asserted from D3hot. bit(15) 1 XXXXb - PME# can be asserted from D3cold. Bridge does not support this state. This field is taken from the private configuration space PME_Support XORed with the PME_Support strap.
26:19	00h RO	Reserved0: Reserved.
18:16	3h RO	Version (VERSION): Indicates support for Revision 1.2 of the PCI Power Management Specification.
15:8	00h RO	Next Capability (NXTCAP): Points to the next capability structure. This points to NULL.
7:0	01h RO	Power Management Capability (POWER_CAP): Indicates this is power management capability.

16.9.12 Power Management Control and Status Register (PMECTRLSTATUS)—Offset 84h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:23, F:0] + 84h

Default: 00000008h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	1
0	0	0	0	0	0	0	0	0
Reserved0	PMESTATUS	Reserved1	PMEENABLE	Reserved2	NO_SOFT_RESET	Reserved3	POWERSTATE	

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Reserved0: Reserved.
15	0h RW/1C	PME Status (PMESTATUS): 0 = Software clears the bit by writing a 1 to it. 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit in this register.
14:9	00h RO	Reserved1: Reserved.
8	0h RW	PME Enable (PMEENABLE): A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0h RO	Reserved2: Reserved.
3	1h RO	No Soft Reset (NO_SOFT_RESET): This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	Reserved3: Reserved.
1:0	0h RW	Power State (POWERSTATE): This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: 00 = D0 state 11 = D3HOT state Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for upstream decode on fabric ports.

16.9.13 General Purpose Read Write Register1 (GEN_REGRW1)—Offset A0h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:23, F:0] + A0h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0

16.10.1 SDMA System Address / Argument 2 Register (SYS_ADR)—Offset 0h

Access Method

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:23, F:0] + 10h

Default: 00000000h

October 2018
Document Number: 538136, Rev. 4.3

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RW	SDMA System Address (sys_adr): (1) SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at each boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates a DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the uppermost byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register. (2) Argument 2 This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

16.10.2 Block Size Register (BLK_SIZE)—Offset 4h

This register is used to configure the number of bytes in a data block.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:23, F:0] + 10h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
tx_blk_size_12	boundary	tr_blk_size		

Bit Range	Default & Access	Field Name (ID): Description
15	0b RW	TX_BLK_SIZE_12 (tx_blk_size_12): Transfer Block Size 12th bit. This bit is added to support 4Kb Data block transfer.

Bit Range	Default & Access	Field Name (ID): Description
15:0	0000h RW	Blocks Count For Current Transfer (blk_count): This register is enabled when Block Count Enable in the Transfer Mode register is set to 1, and is valid only for multiple block transfers. The Host Driver shall set this register to a value between 1 and the maximum block count. The HC decrements the block count after each block transfer, and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (i.e., after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored. When saving transfer context as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, the HD shall restore the previously saved block count. • 0000h = Stop Count • 0001h = 1 block • 0002h = 2 blocks • . . . • FFFFh = 65535 blocks

16.10.4 Argument 1 Register (ARGUMENT)—Offset 8h

This register contains the SD Command Argument.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:23, F:0] + 10h

Default: 00000000h

[illegible]

Bit Range	Default & Access	Field Name (ID): Description
31:0	0h RW	Command Argument 1 (argument): The SD Command Argument is specified as bit39-8 of Command-Format in the Physical Layer Specification.

16.10.5 Transfer Mode Register (TX_MODE)—Offset Ch

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command which transfers data (Refer to Data Present Select in the Command register), or before issuing a Resume command. The Host Driver shall save the value of this register when the data transfer is suspended (as a result of a Suspend command) and restore it before issuing a Resume command. To prevent data loss, the Host Controller shall implement write protection for this register during data transactions. Writes to this register shall be ignored when the Command Inhibit (DAT) in the Present State register is 1.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:23, F:0] + 10h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
rsvd		boot_en	spi_mode	cmd_comp_ata
		blk_sel	data_tr_dir	auto_cmd_en
			blk_count_en	dma_en

Bit Range	Default & Access	Field Name (ID): Description
15:9	00h RO	Reserved (rsvd): Reserved.
8	0b RW	BOOT_EN (boot_en): To start boot operation for MMC4.3 1 - To start boot mode 0 - Stop the boot read
7	0b RW	SPI_MODE (spi_mode): SPI mode enable bit. 1 - SPI mode 0 - SD mode
6	0b RW	CMD_COMP_ATA (cmd_comp_ata): Command Completion Signal Enable for CE-ATA Device. ???1??? - Device will send command completion Signal ???0??? - Device will not send command completion Signal
5	0b RW	BLK_SEL (blk_sel): Multi / Single Block Select This bit is set when issuing multiple-block transfer commands using DAT line. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Table 2-8) 1 Multiple Block 0 Single Block
4	0b RW	Data Transfer Direction Select (data_tr_dir): This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the SD Host Controller, and it is set to 0 for all other commands. 1 = Read (Card to Host) 0 = Write (Host to Card)
3:2	0b RW	AUTO_CMD_EN (auto_cmd_en): This field determines use of auto command functions 00b - Auto Command Disabled 01b - Auto CMD12 Enable 10b - Auto CMD23 Enable 11b - Reserved
1	0b RW	Block Count Enable (blk_count_en): This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. (Refer to Table 2-8). If ADMA2 data transfer is more than 65535 blocks, this bit shall be set to 0. In this case, data transfer length is designated by Descriptor Table. 1 = Enable 0 = Disable
0	0b RW	DMA Enable (dma_en): This bit enables DMA functionality as described in section 1.4. DMA can be enabled only if it is supported as indicated in the Capabilities register. One of the DMA modes can be selected by DMA Select in the Host Control register. If DMA is not supported, this bit is meaningless and shall always read 0. If this bit is set to 1, a DMA operation shall begin when the Host Driver writes to the upper byte of Command register (00Fh). 1 = DMA Data transfer 0 = No data transfer or Non DMA data transfer

16.10.6 Command Register (CMD)—Offset Eh

The Host Driver shall check the Command Inhibit (DAT) bit and Command Inhibit (CMD) bit in the Present State register before writing to this register. Writing to the upper byte of this register triggers SD command generation. The Host Driver has the responsibility to write this register because the Host Controller does not protect for writing when Command Inhibit (CMD) is set.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + Eh

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:23, F:0] + 10h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
rsvd	cmd_index	cmd_type	data_pr_sel	cmd_index_chk_en
			cmd_crc_chk_en	reserved
				resp_type_sel

Bit Range	Default & Access	Field Name (ID): Description
15:14	0h RO	Rsvd (rsvd): Reserved.
13:8	0h RW	Command Index (cmd_index): These bits shall be set to the command number (CMD0-63, ACMD0-63) that is specified in bits 45-40 of the Command-Format in the Physical Layer Specification and SDIO Card Specification.
7:6	00b RW	Command Type (cmd_type): There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. (1) Suspend Command If the Suspend command succeeds, the Host Controller shall assume the SD Bus has been released and that it is possible to issue the next command, which uses the DAT line. The Host Controller shall de-assert Read Wait for read transactions and stop checking busy for write transactions. The interrupt cycle shall start, in 4-bit mode. If the Suspend command fails, the Host Controller shall maintain its current state, and the Host Driver shall restart the transfer by setting Continue Request in the Block Gap Control register. (Refer to 3.12.1 Suspend Sequence). (2) Resume Command The Host Driver re-starts the data transfer by restoring the registers in the range of 000-00Dh. (Refer to Figure 1-4 in section 1.6 for the register map.) The Host Controller shall check for busy before starting write transfers. (3) Abort Command If this command is set when executing a read transfer, the Host Controller shall stop reads to the buffer. If this command is set when executing a write transfer, the Host Controller shall stop driving the DAT line. After issuing the Abort command, the Host Driver should issue a software reset. (Refer to 3.8 Abort Transaction). 11b = Abort -- CMD12, CMD52 for writing 'I/O Abort' in CCCR 10b = Resume -- CMD52 for writing 'Function Select' in CCCR 01b = Suspend -- CMD52 for writing 'Bus Suspend' in CCCR 00b = Normal -- Other commands
5	0b RW	Data Present Select (data_pr_sel): This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following: (1) Commands using only CMD line (ex. CMD52). (2) Commands with no data transfer but using busy signal on DAT[0] line (R1b or R5b ex. CMD38). (3) Resume command. 1 = Data Present 0 = No Data Present

Bit Range	Default & Access	Field Name (ID): Description
4	0b RW	Command Index Check Enable (cmd_index_chk_en): If this bit is set to 1, the Host Controller shall check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked. 1 = Enable 0 = Disable
3	0b RW	Command CRC Check Enable (cmd_crc_chk_en): If this bit is set to 1, the Host Controller shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The position of CRC field is determined according to the length of the response. (Refer to definition in D01-00 and Table 2-10 below.) 1 = Enable 0 = Disable
2	0b RO	Reserved (reserved): Reserved.
1:0	0h RW	Response Type Select (resp_type_sel): 00 = No Response 01 = Response Length 136 10 = Response Length 48 11 = Response Length 48 check Busy after response

16.10.7 Response Register 0 (RESPONSE0)—Offset 10h

This register is used to store responses from SD cards.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 10h

0	0	0	0	0	0	0	0	0

Bit Range	Default & Access	Field Name (ID): Description
31:0	0h RW	Buffer Data (buf_data): The Host Controller buffer can be accessed through this 32-bit Data Port register. Refer to section 1.7.

Bit Range	Default & Access	Field Name (ID): Description
16	1b RO	Card Inserted (crd_ins): This bit indicates whether a card has been inserted. The Host Controller shall debounce this signal so that the Host Driver will not need to wait for it to stabilize. Changing from 0 to 1 generates a Card Insertion interrupt in the Normal Interrupt Status register and changing from 1 to 0 generates a Card Removal interrupt in the Normal Interrupt Status register. The Software Reset For All in the Software Reset register shall not affect this bit. If a card is removed while its power is on and its clock is oscillating, the Host Controller shall clear SD Bus Power in the Power Control register (Refer to Section 2.2.11) and SD Clock Enable in the Clock Control register (Refer to Section 2.2.14). When this bit is changed from 1 to 0, the Host Controller shall immediately stop driving CMD and DAT[3:0] (tri-state). In addition, the Host Driver should clear the Host Controller by the Software Reset For All in Software Reset register. The card detect is active regardless of the SD Bus Power. 1 = Card Inserted 0 = Reset or Debouncing or No Card
15:12	0h RO	Reserved1 (reserved1): Reserved.
11	0b RO	Buffer Read Enable (buf_rd_en): This status is used for non-DMA read transfers. The Host Controller may implement multiple buffers to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is 1, readable data exists in the buffer. A change of this bit from 1 to 0 occurs when all the block data is read from the buffer. A change of this bit from 0 to 1 occurs when block data is ready in the buffer and generates the Buffer Read Ready interrupt. 1 = Read enable 0 = Read disable
10	0b RO	Buffer Write Enable (buf_wr_en): This status is used for non-DMA write transfers. The Host Controller can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, data can be written to the buffer. A change of this bit from 1 to 0 occurs when all the block data is written to the buffer. A change of this bit from 0 to 1 occurs when top of block data can be written to the buffer and generates the Buffer Write Ready interrupt. The Host Controller should neither set Buffer Write Enable nor generate Buffer Write Ready Interrupt after the last block data is written to the Buffer Data Port Register. 1 = Write enable 0 = Write disable
9	0b RO	Read Transfer Active (rd_tx_active): This status is used for detecting completion of a read transfer. Refer to Section 3.12.3 for sequence details. This bit is set to 1 for either of the following conditions: - After the end bit of the read command. - When read operation is restarted by writing a 1 to Continue Request in the Block Gap Control register. This bit is cleared to 0 for either of the following conditions: - When the last data block as specified by block length is transferred to the System. - In case of ADMA2, end of read operation is designated by Descriptor Table. - When all valid data blocks in the Host Controller have been transferred to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1. A Transfer Complete interrupt is generated when this bit changes to 0. 1 = Transferring data 0 = No valid data

Bit Range	Default & Access	Field Name (ID): Description
8	0b RO	Write Transfer Active (wr_tx_active): This status indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the Host Controller. Refer to Section 3.12.4 for more details on the sequence of events. This bit is set in either of the following cases: - After the end bit of the write command. - When write operation is restarted by writing a 1 to Continue Request in the Block Gap Control register. This bit is cleared in either of the following cases: - After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) In case of ADMA2, transfer count is designated by Descriptor Table. - After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request. During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as the result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining non DAT line commands can be issued during write busy. 1 Transferring data 0 No valid data
7:3	00h RO	Reserved (reserved): Reserved.
2	0b RO	DAT Line Active (dat_ln_active): This bit indicates whether one of the DAT lines on SD Bus is in use. (a) In the case of read transactions This status indicates whether a read transfer is executing on the SD Bus. Changing this value from 1 to 0 generates a Block Gap Event interrupt in the Normal Interrupt Status register, as the result of the Stop At Block Gap Request being set. Refer to Section 3.12.3 for details on timing. This bit shall be set in either of the following cases: - After the end bit of the read command. - When writing a 1 to Continue Request in the Block Gap Control register to restart a read transfer. This bit shall be cleared in either of the following cases: - When the end bit of the last data block is sent from the SD Bus to the Host Controller. In case of ADMA2, the last block is designated by the last transfer of Descriptor Table. - When a read transfer is stopped at the block gap initiated by a Stop At Block Gap Request. The Host Controller shall stop read operation at the start of the interrupt cycle of the next block gap by driving Read Wait or stopping SD clock. If the Read Wait signal is already driven (due to data buffer cannot receive data), the Host Controller can continue to stop read operation by driving the Read Wait signal. It is necessary to support Read Wait in order to use suspend / resume function. (b) In the case of write transactions This status indicates that a write transfer is executing on the SD Bus. Changing this value from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register. Refer to Section 3.12.4 for sequence details. This bit shall be set in either of the following cases: - After the end bit of the write command. - When writing to 1 to Continue Request in the Block Gap Control register to continue a write transfer. This bit shall be cleared in either of the following cases: - When the SD card releases write busy of the last data block. If SD card does not drive busy signal for 8 SD Clocks, the Host Controller shall consider the card drive 'Not Busy'. In case of ADMA2, the last block is designated by the last transfer of Descriptor Table. - When the SD card releases write busy prior to waiting for write transfer as a result of a Stop At Block Gap Request. (c) Command with busy This status indicates whether a command indicates busy (ex. erase command for memory) is executing on the SD Bus. This bit is set after the end bit of the command with busy and cleared when busy is de-asserted. Changing this bit from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register. Refer Figure 2-11 to Figure 2-13. 1 = DAT Line Active 0 = DAT Line Inactive

Bit Range	Default & Access	Field Name (ID): Description
1	0b RO	Command Inhibit (DAT) (cmd_inhibit_dat): This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates the Host Controller can issue the next SD Command. Commands with busy signal belong to Command Inhibit (DAT) (ex. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Normal Interrupt Status register. Note: The SD Host Driver can save registers in the range of 000-00Dh for a suspend transaction after this bit has changed from 1 to 0. 1 Cannot issue command which uses the DAT line 0 Can issue command which uses the DAT line
0	0b RO	Command Inhibit (CMD) (cmd_inhibit_cmd): Command Inhibit (CMD) If this bit is 0, it indicates the CMD line is not in use and the Host Controller can issue a SD Command using the CMD line. cleared when the command response is received. Auto CMD12 and Auto CMD23 consist of two responses. In this case, this bit is not cleared by the response of CMD12 or CMD23 but cleared by the response of a read/write command. Status issuing Auto CMD12 is not read from this bit. So if a command is issued during Auto CMD12 operation, Host Controller shall manage to issue two commands: CMD12 and a command set by Command register. Even if the Command Inhibit (DAT) is set to 1, commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete Interrupt in the Normal Interrupt Status register. If the Host Controller cannot issue the command because of a command conflict error (Refer to Command CRC Error in Section 2.2.18) or because of Command Not Issued By Auto CMD12 Error (Refer to Section 2.2.23), this bit shall remain 1 and the Command Complete is not set. 1 Cannot issue command 0 Can issue command using only CMD line

16.10.13 Host Control 1 Register (HOST_CTL)—Offset 28h

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 28h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:23, F:0] + 10h

Default: 00h

7			4				0
0	0	0	0	0	0	0	0
crd_det_sig_sel	crd_det_tst_lvl	sd8_bit_mode	dma_sel	hi_spd_en	data_tx_wid	led_ctl	

Bit Range	Default & Access	Field Name (ID): Description
7	0b RW	Card Detect Signal Selection (crd_det_sig_sel): This bit selects source for the card detection. 1 = The Card Detect Test Level is selected (for test purposes) 0 = SDCD# is selected (for normal use) When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during the period of debouncing.

Bit Range	Default & Access	Field Name (ID): Description
6	0b RW	Card Detect Test Level (crd_det_tst_lvl): This bit is enabled while the Card Detect Signal Selection is set to 1, and it indicates whether or not the card is inserted. 1 = Card Inserted 0 = No Card
5	0b RW	SD8 Bit Mode (sd8_bit_mode): This bit selects the data width of the HC. The HD shall select it to match the data width of the SD card.
4:3	00b RW	DMA Select (dma_sel): One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. 00 = SDMA is selected 01 = Reserved (New assignment is not allowed) 10 = 32-bit Address ADMA2 is selected 11 = Reserved (will be modified by Version 4.00)
2	0b RW	High Speed Enable (hi_spd_en): This bit is optional. Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is set to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock (up to 25MHz). If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock (up to 50MHz). If Preset Value Enable in the Host Control 2 register is set to 1, Host Driver needs to reset SD Clock Enable before changing this field to avoid generating clock glitches. After setting this field, the Host Driver sets SD Clock Enable again. 1 = 4-bit mode 0 = 1-bit mode
1	0b RW	Data Transfer Width (data_tx_wid): Reserved.
0	0b RW	LED Control (led_ctl): This bit selects the data width of the Host Controller. The Host Driver shall set it to match the data width of the SD card. 1 = 4-bit mode 0 = 1-bit mode

16.10.14 Power Control Register (PWR_CTL)—Offset 29h

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 29h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:23, F:0] + 10h

Default: 00h

7	4	0
0	0	0
rsvd	hw_rst	sd_bus_volt_sel
		sd_bus_pwr

Bit Range	Default & Access	Field Name (ID): Description
7:5	0h RO	Rsvd (rsvd): Reserved.

Bit Range	Default & Access	Field Name (ID): Description
4	0b RW	HW Reset (hw_rst): Reserved.
3:1	0h RW	SD Bus Voltage Select (sd_bus_volt_sel): By setting these bits, the Host Driver selects the voltage level for the SD card. Before setting this register, the Host Driver shall check the Voltage Support bits in the Capabilities register. If an unsupported voltage is selected, the Host System shall not supply SD Bus voltage. 111b = 3.3V (Typ.) 110b = 3.0V (Typ.) 101b = 1.8V (Typ.) 100b 000b Reserved
0	0b RW	SD Bus Power (sd_bus_pwr): Before setting this bit, the SD Host Driver shall set SD Bus Voltage Select. If the Host Controller detects the No Card state, this bit shall be cleared. If this bit is cleared, the Host Controller shall immediately stop driving CMD and DAT[3:0] (tri-state) and drive SDCLK to low level (Refer to Section 2.2.14) For SD Controller, this bit controls the bus voltage to SDMMC3. For SDIO Controller, power to SDIO device on SDMMC2 is not controlled by this bit. GPIO register and pin can be used to controller the SDIO device power. For eMMC Controller, power to eMMC device on SDMMC1 is not controlled by this bit. GPIO register and pin or alternative solutions can be used. 1 = Power on 0 = Power off

16.10.15 Block Gap Control Register (_BLK_GAP_CTL)—Offset 2Ah

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 2Ah

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:23, F:0] + 10h

Default: 00h

7	4	0
0	0	0
rsvd	drive_ccsd	int_blk_gap
		rd_wait_ctl
		cont_req
		stp_blk_gap_req

Bit Range	Default & Access	Field Name (ID): Description
7:5	0h RO	Reserved (rsvd): Reserved.
4	0b RW	DRIVE_CCSD (drive_ccsd): If the driver set this bit (change from ???0??? to ???1???), Host controller will send command completion.

Bit Range	Default & Access	Field Name (ID): Description
3	0b RW	Interrupt at Block Gap (int_blk_gap): This bit is valid only in 4-bit mode of the SDIO card and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SD card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card. 1 = Enabled 0 = Disabled
2	0b RW	Read Wait Control (rd_wait_ctl): The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise, the Host Controller has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card. If the card does not support read wait, this bit shall never be set to 1, otherwise DAT line conflict may occur. If this bit is set to 0, Suspend/Resume cannot be supported. 1 = Enable Read Wait Control 0 = Disable Read Wait Control
1	0b RW	Continue Request (cont_req): This bit is used to restart a transaction, which was stopped using the Stop At Block Gap Request. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit 1 to restart the transfer. The Host Controller automatically clears this bit in either of the following cases: - In the case of a read transaction, the DAT Line Active changes from 0 to 1 as a read transaction restarts. - In the case of a write transaction, the Write Transfer Active changes from 0 to 1 as the write transaction restarts. Therefore, it is not necessary for Host Driver to set this bit to 0. If Stop At Block Gap Request is set to 1, any write to this bit is ignored. 1 = Restart 0 = Not affect
0	0b RW	Stop at Block Gap Request (stp_blk_gap_req): This bit is used to stop executing read and write transaction at the next block gap for non-DMA, SDMA and ADMA transfers. The Host Driver shall leave this bit set Copyright 2002-2011 SD Association SD Host Controller Simplified Specification Version 3.00 44 to 1 until the Transfer Complete is set to 1. Clearing both Stop At Block Gap Request and Continue Request shall not cause the transaction to restart. When Host Controller version is 1.00, the Host Driver can set this bit if the card supports Read Wait Control. When Host Controller version is 2.00 or later, the Host Driver can set this bit regardless of the card supports Read Wait Control. The Host Controller shall stop read transfer by using Read Wait or stopping SD clock. In case of write transfers in which the Host Driver writes data to the Buffer Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to Buffer Data Port register. This bit affects Read Transfer Active, Write Transfer Active, DAT Line Active and Command Inhibit (DAT) in the Present State register. Regarding detailed control of bits D01 and D00, refer to Section 3.8 and 3.12. 1 = Stop 0 = Transfer

16.10.16 Wakeup Control Register (WAKEUP_CTL)—Offset 2Bh

This register is mandatory for the Host Controller, but wakeup functionality depends on the Host Controller system hardware and software. The Host Driver shall maintain voltage on the SD Bus, by setting SD Bus Power to 1 in the Power Control register, when wakeup event via Card Interrupt is desired. Wakeup Event is not supported by Host Controller. Sideband wake via GPIO pin and register shall be used instead. During RTD3, GPIO register is readable and GPIO signal is routed to APIC.

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 2Bh

BAR Type: PCI Configuration Register (Size: 32 bits)

15	12	8	4	0
0	0	0	0	0
sdclk_freq_sel				upper_sdclk_freq_sel
				rsvd
				sd_clk_en
				int_clk_stable
				int_clk_en

Bit Range	Default & Access	Field Name (ID): Description
15:8	00h RW	SDCLK Frequency Select (sdclk_freq_sel): This register is used to select the frequency of the SDCLK pin. The definition of this field is dependent on the Host Controller Version. (1) 8-bit Divided Clock Mode This mode is supported by the Host Controller Version 1.00 and 2.00. The frequency is not programmed directly, rather, this register holds the divisor of the Base Clock Frequency For SD Clock in the capabilities register. Only the following settings are allowed. (1) 8-bit Divided Clock Mode 80h = base clock divided by 256 40h = base clock divided by 128 20h = base clock divided by 64 10h = base clock divided by 32 08h = base clock divided by 16 04h = base clock divided by 8 02h = base clock divided by 4 01h = base clock divided by 2 00h = base clock(10MHz and up) Setting 00h specifies the highest frequency of the SD Clock. When setting multiple bits, the most significant bit is used as the divisor, but it should not be set. The three default divider values can be calculated by the frequency that is defined by the Base Clock Frequency For SD Clock in the Capabilities register. 400KHz divider value 25MHz divider value 50MHz divider value According to the Physical Layer Specification, the maximum SD Clock frequency is 25 MHz in normal speed mode and 50MHz in high speed mode, and shall never exceed this limit. The frequency of the SDCLK is set by the following formula: Clock Frequency = (Base Clock) / divisor Thus, choose the smallest possible divisor which results in a clock frequency that is less than or equal to the target frequency. For example, if the Base Clock Frequency For SD Clock in the Capabilities register has the value 33MHz, and the target frequency is 25MHz, then choosing the divisor value of 01h will yield 16.5MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400KHz, the divisor value of 40h yields the optimal clock value of 258KHz. (2) 10-bit Divided Clock Mode Host Controller Version 3.00 supports this mandatory mode instead of the 8-bit Divided Clock Mode. The length of divider is extended to 10 bits, and all divider values shall be supported. 3FFh = 1/2046 Divided Clock - N = 1/2N Divided Clock (Duty 50%) 002h = 1/4 Divided Clock 001h = 1/2 Divided Clock 000h = Base Clock (10MHz and up) 3FFh = Base Clock * M / 1024 - N - 1 = Base Clock * M / N 002h = Base Clock * M / 3 001h = Base Clock * M / 2 000h = Base Clock * M This field depends on setting of Preset Value Enable in the Host Control 2 register. If Preset Value Enable = 0, this field is set by Host Driver. If the Preset Value Enable = 1, this field is automatically set to a value specified in one of Preset Value registers.

Bit Range	Default & Access	Field Name (ID): Description
7:6	0h RO	Upper Bits of SDCLK Frequency Select (upper_sdclk_freq_sel): Host Controller Versions 1.00 and 2.00 do not support these bits and they are treated as 00b fixed value (ROC). Host Controller Version 3.00 shall support these bits to expand SDCLK Frequency Select to 10-bit. Bit 07-06 is assigned to bit 09-08 of clock divider in SDCLK Frequency Select.
5:3	0h RO	Rsvd (rsvd): Reserved.
2	0b RW	SD Clock Enable (sd_clk_en): The Host Controller shall stop SDCLK when writing this bit to 0. SDCLK Frequency Select can be changed when this bit is 0. Then, the Host Controller shall maintain the same clock frequency until SDCLK is stopped (Stop at SDCLK=0). If the Card Inserted in the Present State register is cleared, this bit shall be cleared. 1 = Enable 0 = Disable
1	0b RO	Internal Clock Stable (int_clk_stable): This bit is set to 1 when SD clock is stable after writing to Internal Clock Enable in this register to 1. The SD Host Driver shall wait to set SD Clock Enable until this bit is set to 1. Note: This is useful when using PLL for a clock oscillator that requires setup time. 1 = Ready 0 = Not Ready
0	0b RW	Internal Clock Enable (int_clk_en): This bit is set to 0 when the Host Driver is not using the Host Controller, or when the Host Controller awaits a wakeup event. The Host Controller should stop its internal clock to go to a very low power state. Still, registers shall be able to be read and written. Clock starts to oscillate when this bit is set to 1. When clock oscillation is stable, the Host Controller shall set Internal Clock Stable in this register to 1. This bit shall not affect card detection. 1 = Oscillate 0 = Stop

16.10.18 Timeout Control Register (TIMEOUT_CTL)—Offset 2Eh

At the initialization of the Host Controller, the Host Driver shall set the Data Timeout Counter Value according to the Capabilities register.

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [BAR] + 2Eh

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:23, F:0] + 10h

Bit Range	Default & Access	Field Name (ID): Description
2	0b RW	Software Reset For DAT Line (sw_rst_dat_in): Only part of data circuit is reset. DMA circuit is also reset. The following registers and bits are cleared by this bit: Buffer Data Port register • Buffer is cleared and initialized. Present State register • Buffer Read Enable • Buffer Write Enable • Read Transfer Active • Write Transfer Active • DAT Line Active • Command Inhibit (DAT) Block Gap Control register • Continue Request • Stop At Block Gap Request Normal Interrupt Status register • Buffer Read Ready • Buffer Write Ready • DMA Interrupt • Block Gap Event • Transfer Complete • 1 = Reset • 0 = Work When Auto or Dynamic Clock Gating is enabled for this controller, the Software Reset bit may require several reads before the bit clears.
1	0b RW	Software Reset For CMD Line (sw_rst_cmd_in): Only part of command circuit is reset. The following registers and bits are cleared by this bit: Present State register • Command Inhibit (CMD) Normal Interrupt Status register • Command Complete • 1 = Reset • 0 = Work When Auto or Dynamic Clock Gating is enabled for this controller, the Software Reset bit may require several reads before the bit clears.
0	0b RW	Software Reset For All (sw_rst_all): This reset affects the entire Host Controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared to 0. During its initialization, the Host Driver shall set this bit to 1 to reset the Host Controller. The Host Controller shall reset this bit to 0 when Capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All may not affect the value of the Capabilities registers. If this bit is set to 1, the host driver should issue reset command and reinitialize the SD card. • 1 = Reset • 0 = Work When Auto or Dynamic Clock Gating is enabled for this controller, the Software Reset bit may require several reads before the bit clears.

16.10.20 Normal Interrupt Status Register (NML_INT_STATUS)—Offset 30h

The Normal Interrupt Status Enable affects reads of this register, but Normal Interrupt Signal Enable does not affect these reads. An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. Writing 1 to a bit of RW1C attribute clears it; writing 0 keeps the bit unchanged. Writing 1 to a bit of ROC attribute keeps the bit unchanged. More than one status can be cleared with a single register write. The Card Interrupt is cleared when the card stops asserting the interrupt; that is, when the Card Driver services the interrupt condition.

Access Method

				tx_comp
				cmd_comp

Bit Range	Default & Access	Field Name (ID): Description
15	0b RO	Error Interrupt (err_int): If any of the bits in the Error Interrupt Status register are set, then this bit is set. Therefore the Host Driver can efficiently test for an error by checking this bit first. This bit is read only. 1 = Error 0 = No Error
14	0b RW/1C	BOOT_TER_INT (boot_ter_int): boot ter int
13	0b RW/1C	BOOT_ACK_RCV (boot_ck_rcv): boot ack rcv
12	0b RO	Re-Tuning Event (re_tune): This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. Host Controller requests Host Driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 1 Re-Tuning should be performed 0 Re-Tuning is not required
11	0b RO	INT_C (int_c): This status is set if INT_C is enabled and INT_C# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_C interrupt factor. Refer to the Shared Bus Control register. 1 = INT_C is detected 0 = No interrupt is detected
10	0b RO	INT_B (int_b): This status is set if INT_B is enabled and INT_B# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_B interrupt factor. Refer to the Shared Bus Control register. 1 = INT_B is detected 0 = No interrupt is detected
9	0b RO	INT_A (int_a): This status is set if INT_A is enabled and INT_A# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_A interrupt factor. Refer to the Shared Bus Control register. 1 = INT_A is detected 0 = No interrupt is detected

Bit Range	Default & Access	Field Name (ID): Description
8	0b RO	Card Interrupt (crd_int): Writing this bit to 1 does not clear this bit. It is cleared by resetting the SD card interrupt factor. In 1-bit mode, the Host Controller shall detect the Card Interrupt without SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so there are some sample delays between the interrupt signal from the SD card and the interrupt to the Host System. When this status has been set and the Host Driver needs to start this interrupt service, Card Interrupt Status Enable in the Normal Interrupt Status Enable register may be set to 0 in order to clear the card interrupt statuses latched in the Host Controller and to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset interrupt factors in the SD card and the interrupt signal may not be asserted), set Card Interrupt Status Enable to 1 and start sampling the interrupt signal again. Interrupt detected by DAT[1] is supported when there is a card per slot. In case of shared bus, interrupt pins are used to detect interrupts. If 000b is set to Interrupt Pin Select in the Shared Bus Control register, this status is effective. Non-zero value is set to Interrupt Pin Select, INT_A, INT_B or INT_C is then used to device interrupts. 1 = Generate Card Interrupt 0 = No Card Interrupt
7	0b RW/1C	Card Removal (crd_rm): This status is set if the Card Inserted in the Present State register changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card detect state may possibly be changed when the Host Driver clear this bit and interrupt event may not be generated. 1 = Card removed 0 = Card state stable or Debouncing
6	0b RW/1C	Card Insertion (crd_ins): This status is set if the Card Inserted in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed, because the card detect state may possibly be changed when the Host Driver clears this bit and interrupt event may not be generated. 1 Card inserted 0 Card state stable or Debouncing
5	0b RW/1C	Buffer Read Ready (buf_rd_rdy): This status is set if the Buffer Read Enable changes from 0 to 1. Refer to the Buffer Read Enable in the Present State register. While performing tuning procedure (Execute Tuning is set to 1), Buffer Read Ready is set to 1 for every CMD19 execution. 1 = Ready to read buffer 0 = Not ready to read buffer
4	0b RW/1C	Buffer Write Ready (buf_wr_rdy): This status is set if the Buffer Write Enable changes from 0 to 1. Refer to the Buffer Write Enable in the Present State register. 1 = Ready to write buffer 0 = Not ready to write buffer
3	0b RW/1C	DMA Interrupt (dma_int): This status is set if the Host Controller detects the Host SDMA Buffer boundary during transfer. Refer to the Host SDMA Buffer Boundary in the Block Size register. Other DMA interrupt factors may be added in the future. In case of ADMA, by setting Int field in the descriptor table, Host Controller generates this interrupt. Suppose that it is used for debugging. This interrupt shall not be generated after the Transfer Complete. 1 = DMA Interrupt is generated 0 = No DMA Interrupt
2	0b RW/1C	Block Gap Event (blk_gap_event): If the Stop At Block Gap Request in the Block Gap Control register is set, this bit is set when both a read / write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1. (1) In the case of a Read Transaction This bit is set at the falling edge of the DAT Line Active Status, when the transaction is stopped at SD Bus timing. The Read Wait shall be supported in order to use this function. Refer to Section 3.12.3 for timing details. p1(1) In the case of a Write Transaction This bit is set at the falling edge of Write Transfer Active Status (after getting CRC status at SD Bus timing). Refer to Section 3.12.4 for more details on the sequence of events. 1 = Transaction stopped at block gap 0 = No Block Gap Event

Bit Range	Default & Access	Field Name (ID): Description
1	0b RW/1C	Transfer Complete (tx_comp): This bit is set when a read / write transfer and a command with busy is completed. (1) In the case of a Read Transaction This bit is set at the falling edge of Read Transfer Active Status. This interrupt is generated in two cases. The first is when a data transfer is completed as specified by data length (After the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request in the Block Gap Control register (After valid data has been read to the Host System). Refer to Section 3.12.3 for more details on the sequence of events. (2) In the case of a Write Transaction This bit is set at the falling edge of the DAT Line Active Status. This interrupt is generated in two cases. The first is when the last data is written to the SD card as specified by data length and the busy signal released. The second is when data transfers are stopped at the block gap by setting Stop At Block Gap Request in the Block Gap Control register and data transfers completed. (After valid data is written to the SD card and the busy signal released). Refer to Section 3.12.4 for more details on the sequence of events. (3) In the case of a command with busy This bit is set when busy is de-asserted. Refer to DAT Line Active and Command Inhibit (DAT) in the Present State register. Refer to the spec for the relationship between Transfer Complete and Data Timeout Error. 1 = Command execution is completed 0 = Not complete While performing tuning procedure (Execute Tuning is set to 1), Transfer Complete is not set to 1.
0	0b RW/1C	Command Complete (cmd_comp): This bit is set when get the end bit of the command response. Auto CMD12 and Auto CMD23 consist of two responses. Command Complete is not generated by the response of CMD12 or CMD23 but generated by the response of a read/write command. Refer to Command Inhibit (CMD) in the Present State register for how to control this bit. Command Timeout Error has higher priority than Command Complete. If both bits are set to 1, it can be considered that the response was not received correctly. For a tabular description of the relationship between these two bits, refer to the description of Command Complete in the spec. 1 = Command complete 0 = No command complete

16.10.21 Error Interrupt Status Register (ERR_INT_STATUS)—Offset 32h

Signals defined in this register can be enabled by the Error Interrupt Status Enable register, but not by the Error Interrupt Signal Enable register. The interrupt is generated when the Error Interrupt Signal Enable is enabled and at least one of the statuses is set to 1. Writing to 1 clears the bit, and writing to 0 keeps the bit unchanged. More than one status can be cleared at the one register write.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [BAR] + 32h

BAR Type: PCI Configuration Register (Size: 32 bits)

0	0	0	0	0
0	0	0	0	0
0	0	0	0	0
0	0	0	0	0
0	0	0	0	0

Bit Range	Default & Access	Field Name (ID): Description
15	0b RW	Vendor Specific Error Status (vend_spec_err_status): Reserved.
14	0b RW	Boot Command Timeout Error (boot_cmd_timeout_err): Occur if the boot are access command is issued to the agent which has no permission to access the boot area.
13	0b RW	CEATA Error (ceata_err): Occurs when ATA command termination has occurred due to an error condition the device has encountered.
12	0b RW	Target Response Error (tgt_rsp_err): Occurs when detecting ERROR in m_hresp(dma transaction).
11:10	0h RO	Reserved (rsvd): Reserved.
9	0b RW	ADMA Error (adma_err): This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. 0 = error 1 = no error
8	0b RW	Auto CMD12 Error (cmd12_err): Auto CMD12 and Auto CMD23 use this error status. This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error Status register has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error. 1 = error 0 = no error
7	0b RW	Current Limit Error (cur_limit_err): By setting the SD Bus Power bit in the Power Control register, the Host Controller is requested to supply power for the SD Bus. If the Host Controller supports the Current Limit function, it can be protected from an illegal card by stopping power supply to the card in which case this bit indicates a failure status. Reading 1 means the Host Controller is not supplying power to SD card due to some failure. Reading 0 means that the Host Controller is supplying power and no error has occurred. The Host Controller may require some sampling time to detect the current limit. If the Host Controller does not support this function, this bit shall always be set to 0. 1 = power fail 0 = no error
6	0b RW	Data End Bit Error (data_end_bit_err): Occurs either when detecting 0 at the end bit position of read data which uses the DAT line or at the end bit position of the CRC Status. 1 = error 0 = no error
5	0b RW	Data CRC Error (data_crc_err): Occurs when detecting CRC error when transferring read data which uses the DAT line or when detecting the Write CRC status having a value of other than 010b.
4	0b RW	Data Timeout Error (data_timeout_err): This bit is set when detecting one of following timeout conditions. - Busy timeout for R1b,R5b type - Busy timeout after Write CRC status - Write CRC Status timeout - Read Data timeout 1 = time out 0 = no error

Bit Range	Default & Access	Field Name (ID): Description
3	0b RW	Command Index Error (cmd_index_err): This bit is set if a Command Index error occurs in the command response. 1 = error 0 = no error
2	0b RW	Command End Bit Error (cmd_end_bit_err): This bit is set when detecting that the end bit of a command response is 0. 1 = End Bit Error generated 0 = no error
1	0b RW	Command CRC Error (cmd_crc_err): Command CRC Error is generated in two cases. If a response is returned and the Command Timeout Error is set to 0 (indicating no timeout), this bit is set to 1 when detecting a CRC error in the command response. The Host Controller detects a CMD line conflict by monitoring the CMD line when a command is issued. If the Host Controller drives the CMD line to 1 level, but detects 0 level on the CMD line at the next SD clock edge, then the Host Controller shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict (refer to tabular data in the spec. that explains the relationship between Command CRC Error and Command Timeout Error). 1 = CRC Error Generated. 0 = no error
0	0b RW	Command Timeout Error (cmd_timeout_err): This bit is set only if no response is returned within 64 SD clock cycles from the end bit of the command. If the Host Controller detects a CMD line conflict (in which case Command CRC Error shall also be set, as shown in tabular data in the spec that explains the relationship between this bit and Command CRC Error) this bit shall be set without waiting for 64 SD clock cycles, because the command will be aborted by the Host Controller. 1 = time out 0 = no Error

16.10.22 Normal Interrupt Status Enable (NRM_INT_STATUS_EN)—Offset 34h

Setting to 1 enables Interrupt Status. **Implementation Note:** The Host Controller may sample the card interrupt signal during interrupt period, and may hold its value in the flip-flop. If the **Card Interrupt Status Enable** is set to 0, the Host Controller shall clear all internal signals regarding Card Interrupt.

16.10.32 ADMA Error Status Register (ADMA_ERR_STAT)—Offset 54h

When ADMA Error Interrupt occurs, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. To recover from the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
- ST_CADR: This state is never set because do not generate ADMA error in this state.

- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

15:8	b5h RO	Vendor Version Number (vend_ver_num): This status is reserved for the vendor version number. The Host Driver should not use this status.
7:0	02h RO	Specification Version Number (spec_ver_num): This status indicates the Host Controller Spec. Version. The upper and lower 4-bits indicate the version. • 00h = SD Host Specification Version 1.00 • 01h = SD Host Specification Version 2.00, Including the feature of the ADMA and Test Register • 02h = SD Host Specification Version 3.00 • others = Reserved

17 Serial ATA (SATA)

The SoC has one integrated SATA host controller that supports independent DMA operation on up to 2 ports and supports data transfer rates of 1.5 Gb/s (150 MB/s) and 3.0 Gb/s (300 MB/s). The SATA controller contains two modes of operation—a legacy mode using I/O space, and an AHCI mode using memory space. Software that uses legacy mode will not have AHCI capabilities.

The SoC supports the Serial ATA Specification, Revision 2.6. The SoC also supports several optional sections of the SATA Revision 2.0 Specifications: Extensions to Serial ATA 1.0 Specification, Revision 1.0 (AHCI support is required for some elements).

The SATA controllers feature two sets of interface signals (ports) that can be independently enabled or disabled (they cannot be tri-stated or driven low). Each interface is supported by an independent DMA controller.

The SATA controllers interact with an attached mass storage device through a register interface that is equivalent to that presented by a traditional IDE host adapter. The host software follows existing standards and conventions when accessing the register interface and follows standard command protocol conventions.

Note 1. SATA DevSlp (**Device Sleep**) is not part of revision 2.6 of the SATA specification, with which this processor is compliant. As such, any DEVSLP functionality of this processor is not specification compliant and should not be used.

Note 2. SATA interface transfer rates are independent of UDMA mode settings. SATA interface transfer rates will operate at the bus's maximum speed, regardless of the UDMA mode reported by the SATA device or the system BIOS.

17.1 Signal Descriptions

Please see [Chapter 2, "Physical Interfaces"](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal's function

Table 190. Signals

Signal Name	Direction Plat. Power	Description
SATA_GP[0]	I V1P8S	Serial ATA 0 General Purpose: This is an input pin which can be configured as an interlock switch or as a general purpose I/O, depending on the platform. When used as an interlock switch status indication, this signal should be driven to '0' to indicate that the switch is closed, and to '1' to indicate that the switch is open.
SATA_GP[1]	I V1P8S	Serial ATA 1 General Purpose: Same as above.
SATA_LED#	O V1P8S	Serial ATA LED: This is an open-collector output pin driven during SATA command activity. It is to be connected to external circuitry that can provide the current to drive a platform LED. When active, the LED is on. When tristated, the LED is off.
SATA_TXP[1:0] SATA_TXN[1:0]	O VPCIESATA	Serial ATA Port 1 and 0: These are outbound high-speed differential signals to Port 1 and 0.
SATA_RXP[1:0] SATA_RXN[1:0]	I VPCIESATA	Serial ATA Port 1 and 0: These are inbound high-speed differential signals to Port 1 and 0.
SATA_RCOMP_P SATA_RCOMP_N	O	These pins are used to connect the external resistors used for Rcomp. Please contact your Intel representative for details.

17.2 Features

17.2.1 Supported Features

Table 191. SATA Feature List (Sheet 1 of 2)

Feature	Description
Native Command Queuing (NCQ)	Allows the device to reorder commands for more efficient data transfers
Auto Activate for DMA	Collapses a DMA Setup then DMA Activate sequence into a DMA Setup only
Hot Plug Support	Allows for device detection without power being applied and ability to connect and disconnect devices without prior notification to the system
Asynchronous Signal Recovery	Provides a recovery from a loss of signal or establishing communication after hot plug
3 Gb/s Transfer Rate	Capable of data transfers up to 3 Gb/s
ATAPI Asynchronous Notification	A mechanism for a device to send a notification to the host that the device requires attention

**Table 191. SATA Feature List (Sheet 2 of 2)**

Feature	Description
Host & Link Initiated Power Management	Capability for the host controller or device to request Partial and Slumber interface power states
Staggered Spin-Up	Enables the host to spin up hard drives sequentially to prevent power load problems on boot
Command Completion Coalescing	Reduces interrupt and completion overhead by allowing a specified number of commands to complete and then generating an interrupt to process the commands

Table 192. SATA/AHCI Feature Matrix

Feature	AHCI Disabled	AHCI Enabled
Native Command Queuing (NCQ)	N/A	Supported
Auto Activate for DMA	N/A	Supported
Hot Plug Support	N/A	Supported
Asynchronous Signal Recovery	N/A	Supported
3 Gb/s Transfer Rate	Supported	Supported
ATAPI Asynchronous Notification	N/A	Supported
Host & Link Initiated Power Management	N/A	Supported
Staggered Spin-Up	Supported	Supported
Command Completion Coalescing	N/A	N/A

17.2.2 Theory of Operation

17.2.2.1 Standard ATA Emulation

The SoC contains a set of registers that shadow the contents of the legacy IDE registers. The behavior of the Command and Control Block registers, PIO, and DMA data transfers, resets, and interrupts are all emulated.

Note: The SoC will assert INTR when the master device completes the EDD command regardless of the command completion status of the slave device. If the master completes EDD first, an INTR is generated and BSY will remain '1' until the slave completes the command. If the slave completes EDD first, BSY will be '0' when the master completes the EDD command and asserts INTR. Software must wait for busy to clear (0) before completing an EDD command, as required by the ATA5 through ATA7 (T13) industry standards.

17.2.2.2 48-Bit LBA Operation

The SATA host controller supports 48-bit LBA through the host-to-device register FIS when accesses are performed using writes to the task file. The SATA host controller will ensure that the correct data is put into the correct byte of the host-to-device FIS.

There are special considerations when reading from the task file to support 48-bit LBA operation. Software may need to read all 16-bits. Since the registers are only 8-bits wide and act as a FIFO, a bit must be set in the device/control register, which is at offset 3F6h for primary and 376h for secondary (or their native counterparts).

If software clears Bit 7 of the control register before performing a read, the last item written will be returned from the FIFO. If software sets Bit 7 of the control register before performing a read, the first item written will be returned from the FIFO.

17.2.3 AHCI Operation

The SoC provides hardware support for Advanced Host Controller Interface (AHCI), a programming interface for SATA host controllers developed through a joint industry effort. AHCI defines transactions between the SATA controller and software and enables advanced performance and usability with SATA. Platforms supporting AHCI may take advantage of performance features such as no master/slave designation for SATA devices—each device is treated as a master—and hardware assisted native command queuing. AHCI also provides usability enhancements such as Hot-Plug. AHCI requires appropriate software support (such as, an AHCI driver) and for some features, hardware support in the SATA device or additional platform hardware.

The SoC supports all of the mandatory features of the *Serial ATA Advanced Host Controller Interface Specification*, Revision 1.3 and many optional features, such as hardware assisted native command queuing, aggressive power management, LED indicator support, and Hot-Plug through the use of interlock switch support (additional platform hardware and software may be required depending upon the implementation).

Note: For reliable device removal notification while in AHCI operation without the use of interlock switches (surprise removal), interface power management should be disabled for the associated port.

Bit Range	Default & Access	Description
15	0h RW/1C	Detected Parity Error (DPE): Set when the SATA Controller detects a parity error on its interface.
14	0h RW/1C	Signaled System Error (SSE): Set when SATA Controller generates an SERR#.
13	0h RW/1C	Received Master-Abort Status (RMA): Set when the SATA Controller receives a master abort to a cycle it generated.
12	0h RW/1C	Received Target-Abort Status (RTA): Set when the SATA Controller receives a target abort to a cycle it generated.
11	0h RW/1C	Signaled Target-Abort Status (STA): This bit must be set by a target device whenever it terminates a transaction with Target-Abort. Devices that will never signal Target-Abort do not need to implement this bit.
10:9	1h RO	DEVSEL# Timing Status (DEVT): Controls the device select time for the SATA Controller's PCI interface.
8	0h RW/1C	Master Data Parity Error Detected (DPD): Set when the SATA Controller, as a master, either detects a parity error or sees the parity error line asserted, and the parity error response bit (bit 6 of the command register) is set. This bit can only be set on read completions received from the backbone where there is a parity error.
7	1h RO	Fast Back-to-Back Capable (FBC): Reserved.
6	0b RO	RSVD0: Reserved
5	1h RO	66 MHz Capable (RSV): Reserved.
4	1h RO	Capabilities List (CL): Indicates the presence of a capabilities list. The minimum requirement for the capabilities list must be PCI power management for the SATA Controller.
3	0h RO	Interrupt Status (IS): Reflects the state of INTx# messages, IRQ14 or IRQ15. This bit is set when the interrupt is to be asserted. This bit is a 0 after the interrupt is cleared
2:0	0b RO	RSVD1: Reserved

17.5.4 Revision ID (RID)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

RID: [B:0, D:19, F:0] + 8h

Default: 00h

7	4	0
0	0	0
RID		

Bit Range	Default & Access	Description
7:0	00h RO	Revision ID (RID): Indicates stepping of the host controller hardware.

17.5.5 Programming Interface (PI)—Offset 9h

This register definition depends on the CC.SCC field. When the CC.SCC is 01h(IDE mode), register definition corresponds to 1st table. When CC.SCC is 06h(AHCI mode), register definition follows the 2nd table.

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

PI: [B:0, D:19, F:0] + 9h

Default: 8Ah

7			4				0
1	0	0	0	1	0	1	0
BMS	RSVD0			SNC	SNE	PNC	PNE

Bit Range	Default & Access	Description
7	1h RO	Bus Master Support (BMS): Indicates the SATA Controller supports bus master operation.
6:4	0b RO	RSVD0: Reserved
3	1h RO	Secondary Mode Native Capable (SNC): Indicates that the secondary controller supports both legacy and native modes.
2	0h RW	Secondary Mode Native Enable (SNE): Determines the mode that the secondary channel is operating in. 0 corresponds to 'compatibility', 1 means PCI native. If this bit is set by SW, then the PNE bit must also be set by SW. While in theory these bits can be programmed separately, such a configuration is not supported by today's software and is not supported by this hardware. If this bit is left unchanged before switching, the result is indeterminate.
1	1h RO	Primary Mode Native Capable (PNC): Indicates that the primary controller supports both legacy and native modes.
0	0h RW	Primary Mode Native Enable (PNE): Determines the mode that the primary channel is operating in. 0 corresponds to 'compatibility', 1 means PCI native. If this bit is set by SW, then the SNE bit must also be set by SW. While in theory these bits can be programmed separately, such a configuration is not supported by today's software and is not supported by this hardware. If this bit is left unchanged before switching, the result is indeterminate.

17.5.6 Class Code (CC)—Offset Ah

Access Method

Type: PCI Configuration Register
(Size: 16 bits)

CC: [B:0, D:19, F:0] + Ah

Default: 0106h

15		12		8		4		0
0	0	0	0	0	0	0	1	0
BCC				SCC				

Bit Range	Default & Access	Description
15:8	01h RO	Base Class Code (BCC): Indicates that this is a mass storage device.
7:0	06h RO	Sub Class Code (SCC): The value reported in this field is dependent on MAP.SMS and various fuses and configuration bits. The value is product specific. For VLV this field may read 01h (IDE) or 06h (AHCI).

17.5.7 Cache Line Size (CLS)—Offset Ch

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

CLS: [B:0, D:19, F:0] + Ch

Default: 00h

7			4				0
0	0	0	0	0	0	0	0
CLS							

Bit Range	Default & Access	Description
7:0	00h RO	Cache Line Size (CLS): This register has no meaning for the SATA controller.

17.5.8 Master Latency Timer (MLT)—Offset Dh

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

MLT: [B:0, D:19, F:0] + Dh

Default: 00h

7			4				0
0	0	0	0	0	0	0	0
MLT							

Bit Range	Default & Access	Description
7:0	00h RO	Master Latency Timer (MLT): This register has no meaning for the SATA controller.

17.5.9 Header Type (HTYPE)—Offset Eh

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

HTYPE: [B:0, D:19, F:0] + Eh

Default: 00h

7	4	0
0	0	0
MFD	HL	

Bit Range	Default & Access	Description
7	0h RO	Multi-function Device (MFD): Indicates this controller is not part of a multi-function device.
6:0	00h RO	Header Layout (HL): Indicates that the controller uses a target device layout.

17.5.10 Primary Command Block Base Address (PCMDBA)—Offset 10h

This 8-byte I/O space is used in Native Mode for the Primary Controller's Command Block.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

PCMDBA: [B:0, D:19, F:0] + 10h

Default: 00000001h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	1
RSVD0				BAR				RSVD1
								RTE

Bit Range	Default & Access	Description
31:16	0b RO	RSVD0: Reserved
15:3	0h RW	Base Address (BAR): Base address of the I/O space (8 consecutive I/O locations).
2:1	0b RO	RSVD1: Reserved
0	1h RO	Resource Type Indicator (RTE): Indicates a request for IO space.

17.5.11 Primary Control Block Base Address (PCTLBA)—Offset 14h

This 4-byte I/O space is used in Native Mode for the Primary Controller's Control Block.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

PCTLBA: [B:0, D:19, F:0] + 14h

Default: 00000001h

31	28	24	20	16	12	8	4	0	
0	0	0	0	0	0	0	0	1	
RSVD0				BAR				RSVD1	RTF

Bit Range	Default & Access	Description
31:16	0b RO	RSVD0: Reserved
15:2	0h RW	Base Address (BAR): Base address of the I/O space (4 consecutive I/O locations).
1	0b RO	RSVD1: Reserved
0	1h RO	Resource Type Indicator (RTE): Indicates a request for IO space.

17.5.12 Secondary Command Block Base Address (SCMDBA)—Offset 18h

This 8-byte I/O space is used in Native Mode for the Secondary Controller's Command Block.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

SCMDBA: [B:0, D:19, F:0] + 18h

Default: 00000001h

31	28	24	20	16	12	8	4	0	
0	0	0	0	0	0	0	0	1	
RSVD0				BAR				RSVD1	RTF

Bit Range	Default & Access	Description
31:16	0b RO	RSVD0: Reserved
15:3	0h RW	Base Address (BAR): Base address of the I/O space (8 consecutive I/O locations).
2:1	0b RO	RSVD1: Reserved
0	1h RO	Resource Type Indicator (RTE): Indicates a request for IO space.

17.5.13 Secondary Control Block Base Address (SCTLBA)—Offset 1Ch

This 4-byte I/O space is used in Native Mode for the Secondary Controller's Control Block.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

SCTLBA: [B:0, D:19, F:0] + 1Ch

Default: 00000001h

31	28	24	20	16	12	8	4	0	
0	0	0	0	0	0	0	0	1	
RSVD0				BAR				RSVD1	RTE

Bit Range	Default & Access	Description
31:16	0b RO	RSVD0: Reserved
15:2	0h RW	Base Address (BAR): Base address of the I/O space (4 consecutive I/O locations).
1	0b RO	RSVD1: Reserved
0	1h RO	Resource Type Indicator (RTE): Indicates a request for IO space.

17.5.14 Legacy IDE Base Address / AHCI Index Data Pair Base Address (LBAR)—Offset 20h

This BAR is used to allocate I/O space for the SFF-8038i mode of operation (aka Bus Master IDE) and if CC.SCC is not 01h, it is used to allocate I/O space for the AHCI index/data pair mechanism as well. Note that hardware does not clear the BA bits (including BA4) when switching from IDE mode to non-IDE mode or vice versa. BIOS is responsible for clearing those bits to 0 since the number of writable bits changes after mode switching.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

LBAR: [B:0, D:19, F:0] + 20h

Default: 00000001h

31	28	24	20	16	12	8	4	0	
0	0	0	0	0	0	0	0	1	
RSVD0				BA				RSVD1	RTF

Bit Range	Default & Access	Description
31:16	0b RO	RSVD0: Reserved

When the programming interface is not IDE (i.e. CC.SCC is not 01h), this register is named ABAR. When the programming interface is IDE, this register becomes SIDPBA. Note that hardware does not clear those BA bits when switching from IDE SKU to non-IDE SKU or vice versa. BIOS is responsible for clearing those bits to 0 since the number of writable bits changes after SKU switching (as indicated by a change in CC.SCC). In the case, this register will then have to be re-programmed to a proper value. When the programming interface is not IDE, the register represents a memory BAR allocating space for the AHCI memory registers. Note that bit[31:16] of this register must be programmed to a value greater than 0 to ensure the memory is mapped to an address of 1 MBytes and greater (i.e. ABAR must be 00010000h or greater). Otherwise, memory cycle targeting the ABAR range may not be accepted. When the programming interface is IDE, the register becomes an I/O BAR allocating 16 bytes of I/O space for the I/O mapped registers defined in Memory Registers. Note that although 16 bytes of locations are allocated, only 8 bytes are used as SINDX and SDATA registers; with the remaining 8 bytes preserved for future enhancement.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

ABAR: [B:0, D:19, F:0] + 24h

Default: 00000000h

31																															28				24				20				16				12				8				4				0							
0																															0				0				0				0				0				0				0				0				0			
BA																																																							PF				TP				RTF			

Bit Range	Default & Access	Description
31:4	0h RW	Base Address (BA): When programming interface is non IDE, this is base address of register memory space (aligned to 2 KB). Bits 31:11 are RW, bits 10:4 are RO of 0; When programming interface is IDE, this is base address of the I/O space. Bits 31:16 are RO of 0, bits 15:4 are RW
3	0h RO	Prefetchable (PF): When programming interface is non IDE, this indicates that this range is not prefetch-able
2:1	0h RO	Type (TP): When programming interface is non IDE, this indicates that this range can be mapped anywhere in 32-bit address space
0	0h RO	Resource Type Indicator (RTE): When programming interface is non IDE, this indicates a request for register memory space; When programming interface is IDE, this indicates a request for IO space.

7			4				0
0	0	0	0	0	0	0	0
MGT							

7			4				0
0	0	0	0	0	0	0	0
MLAT							

17.5.22 Secondary Timing (STIM)—Offset 42h

This controls the timings driven on the parallel cable.

Access Method

Type: PCI Configuration Register
(Size: 16 bits)

STIM: [B:0, D:19, F:0] + 42h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
DE	D1STE	ISP	RSVD0	RCT
			DTE1	PPE1
			IE1	TIM1
			DTE0	PPE0
			IE0	TIM0

Bit Range	Default & Access	Description
15	0h RW	Decode Enable (DE): Enables the SATA Controller to decode the Command Blocks (1F0-1F7h for primary, 170-177h for secondary or their native BAR equivalents) and Control Block (3F6h for primary and 376h for secondary or their native BAR equivalents). This bit still has functionality in SATA - if this bit is not set, the port that is mapped to this range will not be decoded.
14	0h RW	Device 1 Separate Timing Enable (D1STE): This register is not used by SATA controller.
13:12	0h RW	IORDY Sample Point (ISP): This register is not used by SATA controller.
11:10	0b RO	RSVD0: Reserved
9:8	0h RW	Recovery Time (RCT): This register is not used by SATA controller.
7	0h RW	Device 1 DMA Timing Enable (DTE1): This register is not used by SATA controller.
6	0h RW	Device 1 Prefetch/Posting Enable (PPE1): This register is not used by SATA controller.
5	0h RW	Device 1 IORDY Sample Point Enable (IE1): This register is not used by SATA controller.
4	0h RW	Device 1 Fast Timing Bank (TIM1): This register is not used by SATA controller.
3	0h RW	Device 0 DMA Timing Enable (DTE0): This register is not used by SATA controller.
2	0h RW	Device 0 Prefetch/Posting Enable (PPE0): This register is not used by SATA controller.
1	0h RW	Device 0 IORDY Sample Point Enable (IE0): This register is not used by SATA controller.
0	0h RW	Device 0 Fast Timing Bank (TIM0): This register is not used by SATA controller.

17.5.23 Device 1 IDE Timing (D1TIM)—Offset 44h

This register is not used by SATA controller.

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

D1TIM: [B:0, D:19, F:0] + 44h

Default: 00h

7	4	0
0	0	0
RSVD		

Bit Range	Default & Access	Description
7:0	0h RW	RSVD: Reserved

17.5.24 Synchronous DMA Control (Synchronous_DMA_Control)—Offset 48h

This register is not used by SATA controller.

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Synchronous_DMA_Control: [B:0, D:19, F:0] + 48h

Default: 00h

7	4	0
0	0	0
RSVD		

Bit Range	Default & Access	Description
7:0	0h RW	RSVD: Reserved

17.5.25 Synchronous_DMA_Timing—Offset 4Ah

This register is not used by SATA controller.

Access Method

Type: PCI Configuration Register
(Size: 16 bits)

Synchronous_DMA_Timing: [B:0, D:19, F:0] + 4Ah

Default: 0000h

15	12	8	4	0
0	0	0	0	0
RSVD				

17.5.26 IDE I/O Configuration (IIOC)—Offset 54h

Bit Range	Default & Access	Description
15:11	08h RO	PME_Support: By default with CC.SCC=01h, the default value is 00000 which indicates no PME Support in IDE mode. When CC.SCC is not 01h in non-IDE mode, the default value is 01000 which indicates PME# can be generated from the D3HOT state in the SATA controller.
10	0h RO	D2_Support: The D2 state is not supported.
9	0h RO	D1_Support: The D1 state is not supported.
8:6	0h RO	Aux_Current: PME# from D3COLD state is not supported, therefore this field is 000b.
5	0h RO	Device Specific Initialization (DSI): Indicates that no device-specific initialization is required.
4	0b RO	RSVD0: Reserved
3	0h RO	PME Clock (PMEC): Indicates that PCI clock is not required to generate PME#.
2:0	3h RO	Version (VS): Indicates support for Revision 1.2 of the PCI Power Management Specification.

Access Method

PMCS: [B:0, D:19, F:0] + 74h

Default: 0008h

Bit Range	Default & Access	Description
15	0h RW	PME Status (PMES): This bit is set when a PME event is to be requested, and if this bit is set and PMEE is set, a PME# will be generated. -Note: Whenever CC.SCC=01h either by default or just being updated, hardware shall automatically change the attribute to RO of 0.
14:9	0b RO	RSVD0: Reserved

Bit Range	Default & Access	Description
8	0h RW	PME Enable (PMEE): When CC.SCC is not 01h, this bit is RW. When set, the SATA controller generates PME# from D3HOT on a wake event. Whenever CC.SCC=01h either by default or just being updated, hardware shall automatically change the attribute to RO of 0 since there is no PME Support in IDE mode. Note: Software is advised to clear PMEE together with PMES prior to changing CC.SCC thru MAP.SMS.
7:4	0b RO	RSVD1: Reserved
3	1h RO	No Soft Reset (NSFRST): A 1 indicates that devices transitioning from D3hot to D0 because of Power_State commands do not perform an internal reset. Configuration context is preserved. Upon transition from the D3hot to the D0 initialized state, no additional operating system intervention is required to preserve configuration context beyond writing to the Power_State bits. Regardless of this bit, the controller transition from D3hot to the D0 by a system or bus segment reset will return to the state D0 uninitialized with only PME context preserved if PME is supported and enabled.
2	0b RO	RSVD2: Reserved
1:0	0h RW	Power State (PS): This field is used both to determine the current power state of the SATA Controller and to set a new power state. The values are: 00 = D0 state; 11 = D3HOT state. When in the D3HOT state, the controller's configuration space is available, but the I/O and memory spaces are not. Additionally, interrupts are blocked. If software attempts to write a 10 or 01 to these bits, the write will be ignored. Refer to PCI PM specification section 8.2.2. on software requirements in ensuring I/O space, memory space and Bus Master are disabled prior to entering D3 state.

17.5.30 Message Signaled Interrupt Identifier (MID)—Offset 80h

Access Method

Type: PCI Configuration Register
(Size: 16 bits)

MID: [B:0, D:19, F:0] + 80h

Default: 7005h

15			12				8				4				0
0	1	1	1	0	0	0	0	0	0	0	0	0	1	0	1
NEXT							CTD								

Bit Range	Default & Access	Description
15:8	70h RW/L	Next Pointer (NEXT): Indicates the next item in the list is the PCI power management pointer. This is the recommended value. BIOS may program this field to A8h indicating that the next item is Serial ATA Capability structure. The RW/L register attribute allows for flexibility in determining the capability structure available in this PCI function. Refer to SATAGC.REGLOCK description in order to lock the register to become RO.
7:0	05h RO	Capability ID (CID): Capabilities ID indicates MSI.

17.5.31 Message Signaled Interrupt Message Control (MC)—Offset 82h

Access Method

Type: PCI Configuration Register
(Size: 16 bits)

MC: [B:0, D:19, F:0] + 82h

Default: 0000h

Bit Range	Default & Access	Description
15:8	0b RO	RSVD0: Reserved
7	0h RO	64 Bit Address Capable (C64): Capable of generating a 32-bit message only.
6:4	0h RO	Multiple Message Enable (MME): When this field is cleared to 000 (and MSIE is set), only a single MSI message will be generated for all SATA ports, and bits [15:0] of the message vector will be driven from MD[15:0].
3:1	0h RO	Multiple Message Capable (MMC): Not supported.
0	0h RW	MSI Enable (MSIE): If set, MSI is enabled and traditional interrupt pins are not used to generate interrupts. Note that CMD.ID bit has not effect on MSI. Software must clear this bit to 0 to disable MSI first before changing the number of messages allocated in the MMC field. Software must also make sure this bit is cleared to 0 when operating in legacy mode (for AHCI SKUs when GHC.AE = 0). This bit is RW when CC.SCC is not 01h and is read-only 0 when CC.SCC is 01h.

17.5.32 Message Signaled Interrupt Message Address (MA)—Offset 84h

Bit Range	Default & Access	Description
31:2	0h RW	Address (ADDR): Lower 32 bits of the system specified message address, always DWORD aligned.
1:0	0b RO	RSVD0: Reserved

17.5.33 Message Signaled Interrupt Message Data (MD)—Offset 88h

Default: 0000h

Bit Range	Default & Access	Description
5	1h RW	SATA Port-to-Controller Configuration (SC): This bit changes number of SATA port availability within each SATA controller. When MAP.SPD[5] is 1 and MAP.SPD[4] is 1, this bit is reserved and is read-only 1 else it's RW-zero. When this bit is 0: Up to 2 SATA ports are available in the SATA controller 1 with port[1:0]. When this bit to 1: Up to 2 SATA ports are available in the SATA controller 1 with port [1:0]. For SMS=IDE mode, this bit should be 0 (note that this irrespective of the number of SATA ports). The number of port availability in this controller shall be discoverable thru this controller's config PCS.PxE, AHCI CAP.NP and AHCI PI[x] register fields. Prior to changing the state of this bit, all ports must be in quiescent state with no commands outstanding. Refer to Single and Dual Controller Switching Requirement for additional software and hardware requirements.
4:2	0b RO	RSVD1: Reserved
1:0	0h RO	Map Value (MV): This register is reserved.

17.5.35 Port Control and Status (PCS)—Offset 92h

By default, the SATA ports are set (by hardware) to the disabled state (e.g. bits[5:0] == 0) as a result of an initial power on reset. When enabled by software, the ports can transition between the on, partial, and slumber states and can detect devices. When disabled, the port is in the off state and cannot detect any devices. Note: AHCI specific notes: If an AHCI-aware or RAID enabled operating system is being booted then system BIOS shall insure that all supported SATA ports are enabled prior to passing control to the OS. Once the AHCI aware OS is booted it becomes the enabling/disabling policy owner for the individual SATA ports. This is accomplished by manipulating a port's PxSCTL.DET and PxCMD.SUD fields. Because an AHCI or RAID aware OS will typically not have knowledge of the PxE bits and because the PxE bits act as master on/off switches for the ports, pre-boot software must insure that these bits are set to 1 prior to booting the OS, regardless as to whether or not a device is currently on the port.

Access Method

Type: PCI Configuration Register
(Size: 16 bits)

PCS: [B:0, D:19, F:0] + 92h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
ORM	RSVD0	RSVD	P1P	P0P
			RSVD1	P1E
				P0E

Bit Range	Default & Access	Description
15	0h RW	OOB Retry Mode (ORM): When cleared, the SATA controller will not retry after an OOB failure. When set, the SATA controller will continue to retry after an OOB failure until successful (infinite retry). BIOS is requested to program this field to 1.
14	0b RO	RSVD0: Reserved
13:10	0h RO	RSVD: Reserved
9	0h RO	Port 1 Present (P1P): Same as P0P, except for port 1.

Bit Range	Default & Access	Description
8	0h RO	Port 0 Present (POP): When set, the SATA controller has detected the presence of a device on port 0. It may change at any time. Clearing POE bit leads to clearing of this bit after implementation delay. Note: For system software that intends to clear all PCS.PxE bits that are previously 1 to 0 and then to 1 again in two consecutive write cycles, software shall poll on this bit being 0 before setting POE bit to 1.
7:2	0b RO	RSVD1: Reserved
1	0h RW	Port 1 Enabled (P1E): When MAP.SPD[1] is 1, this bit is reserved and read-only 0. Otherwise if none of the above is true, this bit is RW and same as POE but for port 1 and takes precedence over P1CMD.SUD.
0	0h RW	Port 0 Enabled (POE): When MAP.SPD[0] is 1, this bit is reserved and read-only 0. When set, the port is enabled. When cleared, the port is disabled. When enabled, the port can transition between the on, partial, and slumber states and can detect devices. When disabled, the port is in the off state and cannot detect any devices. This bit takes precedence over P0CMD.SUD. Note: The recommendation for software code that intends to clear all PCS.PxE bits that are previously 1 to 0 and then to 1 again immediately shall refer to the polling requirement as described in POP register bit. At any time that BIOS or software is clearing PCS.PxE from 1 to 0, due to time needed for port staggering hardware process (up to 2 ports) to complete, BIOS and software shall delay the write to set the TM.PCD register by 1.4 μ s.

17.5.36 Test Mode Register (TM)—Offset 94h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

TM: [B:0, D:19, F:0] + 94h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RSVD		PCD	RSVD0					

Bit Range	Default & Access	Description
31:26	0h RO	Reserved (RSVD): Reserved.
25:24	0h RW	Port Clock Disable (PCD): When any of these bits is set to 1, the backbone clock driven to the associated port logic is gated and will not toggle. When this bit is cleared to 0, all clocks to the associated port logic will operate normally.
23:0	0b RO	RSVD0: Reserved

17.5.37 SATA General Configuration (SATAGC)—Offset 9Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

SATAGC: [B:0, D:19, F:0] + 9Ch

Default: 00000000h

31				28				24				20				16				12				8				4				0							
0				0				0				0				0				0				0				0				0							
REGLOCK				RSVD0				WRRSELMPS				RSVD1				URRE				URD				AIE				DEVIDSEL				FLRCSSEL				RSVD2			

Bit Range	Default & Access	Description
31	0h RW/O	Register Lock (REGLOCK): BIOS can set this bit to 1 to lock the following registers with RW/L attribute: CAP,CP, MID.NEXT, PIE.NEXT, SATACR0.NEXT. Once locked the register attribute of above list changes from RW/L to RO holding the existing value. BIOS is requested to program this field to 1 prior to hand off to OS. If BIOS needs the SATA host controller to change operation a few times (i.e. changing CC.SCC mode) and need different capability structures for each specific operation mode, BIOS need not activate the lock until BIOS is ready to hand off to OS. BIOS may need to separate write access to this byte offset (x9Fh) from write to the lower 3-byte of the dword (x9C-9Eh) if there is a need to program the lower 3-byte dword location early during boot process.
30:15	0b RO	RSVD0: Reserved
14:12	0h RW	Write Request_Size Select/Max_Payload_Size (WRRSELMP): These two bits select the max write request size that SATA host controller will initiate for DMA write to memory. SATA host controller will internally break up larger write request based on these bits. The request is address-aligned to the selected size. Defined encodings for this field are: 000b = 128 address aligned bytes max payload size; 111b = 64 address aligned bytes max payload size. All other values are reserved for SATA host controller.
11:10	0b RO	RSVD1: Reserved
9	0h RW	Unsupported Request Reporting Enable (URRE): If set to 1 by software, it allows reporting of an Unsupported Request as a system error. If both URRE and PCI configuration SERR# Enable registers are set to a 1, then the agent must set the Signaled System Error bit in the PCI Status register and send a DO_SERR message in IOSF-SB interface.
8	0h RW/1C	Unsupported Request Detected (URD): Set to 1 by hardware upon detecting an Unsupported Request on IOSF Primary interface that is not considered Advisory Non-Fatal. Cleared to 0 by SW.
7	0h RW/O	Alternate ID Enable (AIE): When programmed to 0, HW will report the following device id's: 2822h for desktop or 282Ah for mobile. When programmed to a 1, HW will not report these device id's. The value is product specific. Note: Programming this bit to a 1 will prevent the Windows in-box version of the Intel AHCI driver from loading on the platform - will require that the user perform an 'F6' install of the Intel driver that is appropriate for the reported DID. This field is applicable when the AHCI is configured for RAID mode of operation. It has no impact for AHCI and IDE modes of operation. Note: BIOS is recommended to program this bit prior to programming the MAP.SMS field to reflect RAID. This field is reset by Backbone Reset and BIOS is required to reprogram the value (either 0 or 1) after resuming from S3, S4 or S5. This insures that the value is properly and cannot be changed during runtime.
6	0h RW/O	AIE0 DevID Selection (DEVIDSEL): This register allows BIOS to select Device ID when AIE=0 and Server Feature Disable Fuse 7 =0. This bit only has effect in Desktop SKU. In Mobile SKU this bit has no effect at all. Refer to config register offset 09h PI for usage. 0 : 2822h; 1 : 2826h. NOTE: When Server Feature (SATA AIE DEVIDSEL) Disable Fuse 7 is programmed to 1, this disables the writeability of this DEVIDSEL register bit, and becomes RO with a value of 0, which only allows a choice of 2822h.
5	0h RW/O	FLR Capability Selection (FLRCSSEL): This allows the FLR Capability to be bypassed. Refer to config offset B0h. BIOS is requested to program this bit to 1 and config offset A8h SATACR0.NEXT to 00h.
4:0	0b RO	RSVD2: Reserved

17.5.38 SATA Initialization Register Index (SIRI)—Offset A0h

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

SIRI: [B:0, D:19, F:0] + A0h

Default: 00h

7	4	0
0	0	0
IDX		RSVD0

Bit Range	Default & Access	Description
7:2	00h RW	Index (IDX): 6-bit index pointer into the 256-byte space. Data is written into the SIRD register and read from the SIRD register. This point to a DWord register. The byte enables on the SIRD register affect what will be written. Note that this 256-byte register space setting is applicable to all ports in both SATA controllers 1 and 2 (if supported). Refer to SATA Initialization Register section for detail of the register space.
1:0	0b RO	RSVD0: Reserved

17.5.39 SATA Initialization Register Data (SIRD)—Offset A4h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

SIRD: [B:0, D:19, F:0] + A4h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
DTA								

Bit Range	Default & Access	Description
31:0	00000000h RW	Data (DTA): 32-bit data value that is written to the register pointed to by SIRI, or read from the register pointed to by SIRI.

17.5.40 Serial ATA Capability Register 0 (SATACR0)—Offset A8h

This register shall be read-only 0 when CC.SCC is 01h. Note that the SATACR0.NEXT is not changed from RO to become RWO because there is an existing method (SATAGC.FLRCSSEL bit) to bypass the FLR Capability structure. And FLR Capability ID.NEXT is already indicating end of capability structure, it does not need change to be RWO.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

SATACR0: [B:0, D:19, F:0] + A8h

Default: 00100012h

Bit Range	Default & Access	Description
31:24	0b RO	RSVD0 : Reserved
23:20	1h RO	Major Revision (MAJREV) : Major revision number of the SATA Capability Pointer implemented.
19:16	0h RO	Minor Revision (MINREV) : Minor revision number of the SATA Capability Pointer implemented.
15:8	00h RW/L	Next Capability Pointer (NEXT) : 00h indicating the final item in the Capability List. The RW/L register attribute allows for flexibility in determining the capability structure available in this PCI function. Refer to SATAGC.REGLOCK description in order to lock the register to become RO.
7:0	12h RO	Capability ID (CAP) : The value of 12h has been assigned by the PCI SIG to designate the SATA Capability pointer.

17.5.41 Serial ATA Capability Register 1 (SATACR1)—Offset ACh

Access Method

SATACR1: [B:0, D:19, F:0] + ACh

Bit Range	Default & Access	Description
31:16	0b RO	RSVD0: Reserved
15:4	004h RO	BAR Offset (BAROFST): Indicates the offset into the BAR where the AHCI Index/Data pair are located (in Dword granularity). The Index and Data I/O registers are located at offset 10h within the I/O space defined by LBAR (BAR4). A value of 004h indicates offset 10h. 000h = 0h offset; 001h = 4h offset; 002h = 8h offset; 003h = Ch offset; 004h = 10h offset ... FFFh = 3FFFh offset (max 16 KB)
3:0	8h RO	BAR Location (BARLOC): Indicates the absolute PCI Configuration Register address of the BAR containing the Index/Data pair (in Dword granularity). The Index and Data I/O registers reside within the space defined by LBAR (BAR4) in the SATA controller. A value of 8h indicates offset 20h, which is LBAR (BAR4). 0000 - 0011b = reserved; 0100b = 10h =) BAR0; 0101b = 14h =) BAR1; 0110b = 18h =) BAR2; 0111b = 1Ch =) BAR3; 1000b = 20h =) LBAR; 1001b = 24h =) BAR5; 1010 - 1110b = reserved; 1111b = Index/Data pair in PCI Configuration space which is not supported.

17.5.42 FLR Capability ID (FLRCID)—Offset B0h

Access Method

Type: PCI Configuration Register
(Size: 16 bits)

FLRCID: [B:0, D:19, F:0] + B0h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
NEXT			CID	

Bit Range	Default & Access	Description
15:8	00h RO	Next Capability (NEXT): 00h indicating the final item in the Capability List.
7:0	00h RO	Capability ID (CID): The value of this field depends on the FLRCSSSEL bit. SATAGC.FLRCSSSEL = 0, Capability ID = 13h; SATAGC.FLRCSSSEL = 1, Capability ID = 00h (capability is bypassed).

17.5.43 FLR Control (FLRCTL)—Offset B4h

This register shall be read-only 0 when SATAGC.FLRCSEL=1.

Access Method

Type: PCI Configuration Register
(Size: 16 bits)

FLRCTL: [B:0, D:19, F:0] + B4h

Default: 0000h

	15			12					8					4					0
	0	0	0	0		0	0	0	0		0	0	0	0		0	0	0	0
	RSVD																		

Bit Range	Default & Access	Description
15:0	0h RO	RSVD: Reserved

17.5.44 Scratch Pad (SP)—Offset D0h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

SP: [B:0, D:19, F:0] + D0h

Default: 00000000h

31 28 24 20 16 12 8 4 0

0 0 0 0 | 0 0 0 0 | 0 0 0 0 | 0 0 0 0 | 0 0 0 0 | 0 0 0 0 | 0 0 0 0 | 0 0 0 0

DT

Bit Range	Default & Access	Description
31:0	0h RW	Data (DT): This is a read/write register that is available for software to use. No hardware action is taken on this register.

17.5.45 BIST FIS Control/Status (BFCS)—Offset E0h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

BFCS: [B:0, D:19, F:0] + E0h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
						BFS	BFF	P1BFI
						P0BFI		BFP
								RSVD1

Bit Range	Default & Access	Description
31:12	0b RO	RSVD0: Reserved
11	0h RW	BIST FIS Successful (BFS): This bit is set any time that a BIST FIS transmitted by the SATA controller receives an R_OK completion status from the device
10	0h RW	BIST FIS Failed (BFF): This bit is set any time that a BIST FIS transmitted by the SATA controller receives an R_ERR completion status from the device
9	0h RW	Port 1 BIST FIS Initiate (P1BFI): When a rising edge is detected on this bit, the SATA controller will initiate a BIST FIS to the device on port 1, using the parameters specified in this register and BFTD1 and BFTD2. The BIST FIS will only be initiated if a device is present and not in the partial or slumber states. After a BIST FIS is successfully completed, software must disable and re-enable PCS.P1E prior to attempting additional BIST FISes or to return the SATA controller to a normal operational mode. If the BIST FIS fails, as indicated by BFF in this register, software can clear and then set this bit to initiate another BIST FIS.
8	0h RW	Port 0 BIST FIS Initiate (P0BFI): When a rising edge is detected on this bit, the SATA controller will initiate a BIST FIS to the device on port 0, using the parameters specified in this register and BFTD1 and BFTD2. The BIST FIS will only be initiated if a device is present and not in the partial or slumber states. After a BIST FIS is successfully completed, software must disable and re-enable PCS.P0E prior to attempting additional BIST FISes or to return the SATA controller to a normal operational mode. If the BIST FIS fails, as indicated by BFF in this register, software can clear and then set this bit to initiate another BIST FIS.
7:2	0h RW	BIST FIS Parameters (BFP): These bits form the contents of the upper 6 bits of the BIST FIS Pattern Definition in the BIST FIS transmitted by the SATA controller. This field is not port specific - its contents will be used for any BIST FIS initiated on the SATA controller. The specific bit definitions are: Bit 7 (T) Far End Transmit mode; bit 6 (A) Align Bypass mode; bit 5 (S) Bypass Scrambling; bit 4 (L) Far End Retimed Loopback; bit 3 (F) Far End Analog Loopback; bit 2 (P) Primitive bit for use with Transmit mode.
1:0	0b RO	RSVD1: Reserved

17.5.46 BIST FIS Transmit Data 1 (BFTD1)—Offset E4h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

BFTD1: [B:0, D:19, F:0] + E4h

Bit Range	Default & Access	Description
27:24	8h RO	Dot portion of Process ID (DPID): Indicates the dot. Process is reflected in bits [7:0]. The value is product specific.
23:16	0h RO	Stepping Identifier (SID): This field is incremented for each stepping of the part. Note that this field can be used by software to differentiate steppings when the Revision ID may not change. The value is product specific.
15:8	0Fh RO	Manufacturer Identifier (MID): Indicates Intel.
7:0	B1h RO	Process/Dot Identifier (PID): Indicates the Process. Dot is reflected in bits [27:24]. The value is product specific.

17.6 SATA Legacy IO Registers

Table 194. Summary of SATA Legacy I/O Registers—LBAR

Offset	Size	Register ID—Description	Default Value
0h	1	"Primary Command (PCMD)—Offset 0h" on page 1961	00h
2h	1	"Primary Status (PSTS)—Offset 2h" on page 1962	00h
4h	4	"Primary Descriptor Table Pointer (PDTP)—Offset 4h" on page 1962	00000000h
8h	1	"Secondary Command (SCMD)—Offset 8h" on page 1963	00h
Ah	1	"Secondary Status (SSTS)—Offset Ah" on page 1963	00h
Ch	4	"Secondary Descriptor Table Pointer (SDTP)—Offset Ch" on page 1964	00000000h
10h	4	"AHCI Index Register (INDEX)—Offset 10h" on page 1965	00000000h
14h	4	"AHCI Data Register (DATA)—Offset 14h" on page 1966	00000000h

17.6.1 Primary Command (PCMD)—Offset 0h

Access Method

Type: I/O Register
(Size: 8 bits)

PCMD: [LBAR] + 0h

LBAR Type: PCI Configuration Register (Size: 32 bits)

LBAR Reference: [B:0, D:19, F:0] + 20h

Default: 00h

7	4	0
0	0	0
RSVD0	RWC	RSVD1
		START

Bit Range	Default & Access	Description
7:4	0b RO	RSVD0: Reserved
3	0h RW	Read / Write Control (RWC): Sets the direction of the bus master transfer: 0 = memory to device, 1 = device to memory. This bit must not be changed when the bus master function is active.
2:1	0b RO	RSVD1: Reserved
0	0h RW	Start/Stop Bus Master (START): Setting this bit enables bus master operation of the controller. Bus master operation does not actually start unless the Bus Master Enable bit in PCI configuration space is also set. Clearing it halts bus master operation. All state information is lost when this bit is written to 0; Master mode operation cannot be stopped and then resumed. If this bit is reset while bus master operation is still active and the device has not yet finished its data transfer, the bus master command is said to be aborted. If this bit is cleared to 0 prior to the DMA data transfer being initiated by the drive in a device to memory data transfer, then not DMAT will be sent to terminate the data transfer. SW intervention (e.g. sending SRST) is required to reset the interface in this condition. This bit is intended to be cleared by software after the data transfer is completed - as indicated by either the ACT bit being cleared in the status register, or the I bit being set in the status register, or both.

Bit Range	Default & Access	Description
7	0h RO	Simplex Only (S): This read-only bit indicates whether or not I both bus master channels (primary and secondary) can be operated at the same time. If the bit is a 0, then the channels operate independently and can be used at the same time. If the bit is a 1, then only one channel may be used at a time.
6	0h RW	Device 1 DMA Capable (D1DC): A scratchpad bit set by SW to indicate that device 1 of this channel is capable of DMA transfers. This bit has no effect on the hardware.
5	0h RW	Device 0 DMA Capable (D0DC): A scratchpad bit set by SW to indicate that device 0 of this channel is capable of DMA transfers. This bit has no effect on the hardware.
4:3	0b RO	RSVD0: Reserved
2	0h RW/1C	Interrupt (I): This bit is set when a device FIS is received with the I bit has been set provided that software has not disabled interrupt via the nIEN bit of Device Control Register.
1	0h RW/1C	Error (ERR): This bit is set when the controller encounters an error during the transfer and must stop the transfer. See Error Handling for the list of errors that set this bit.
0	0h RO	Active (ACT): Set by the host when the START bit is written to the Command register, and cleared by the host when the last transfer for a region is performed, where EOT for that region is set in the region descriptor, and when the START bit is cleared in the Command register and the controller has returned to an idle condition.

17.6.3 Primary Descriptor Table Pointer (PDTP)—Offset 4h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
DBA								RSVD0

Bit Range	Default & Access	Description
31:2	00000000h RW	Descriptor Base Address (DBA): Corresponds to A[31:2]. This table must not cross a 64K boundary in memory. When read, the current value of the pointer is returned
1:0	0b RO	RSVD0: Reserved

17.6.4 Secondary Command (SCMD)—Offset 8h

Access Method

Type: I/O Register
(Size: 8 bits)

SCMD: [LBAR] + 8h

LBAR Type: PCI Configuration Register (Size: 32 bits)

LBAR Reference: [B:0, D:19, F:0] + 20h

Default: 00h

7				4					0
0		0		0		0		0	0
RSVD0					RWC		RSVD1		START

Bit Range	Default & Access	Description
7:4	0b RO	RSVD0: Reserved
3	0h RW	Read / Write Control (RWC): Sets the direction of the bus master transfer: 0 = memory to device, 1 = device to memory. This bit must not be changed when the bus master function is active.
2:1	0b RO	RSVD1: Reserved
0	0h RW	Start/Stop Bus Master (START): Setting this bit enables bus master operation of the controller. Bus master operation does not actually start unless the Bus Master Enable bit in PCI configuration space is also set. Clearing it halts bus master operation.

17.6.5 Secondary Status (SSTS)—Offset Ah

Access Method

Type: I/O Register
(Size: 8 bits)

SSTS: [LBAR] + Ah

0	0	0	0	0	0	0	0	0

DATA

Bit Range	Default & Access	Description
31:0	00000000h RW	Data (DATA): This Data register is a window through which data is read or written to the memory mapped register pointed to by the Index register. Note that a physical register is not actually implemented as the data is actually stored in the memory mapped registers. Since this is not a physical register, the default value is the same as the default value of the register pointed to by Index.

17.7.2 Serial ATA Data (SDATA)—Offset 4h

All of these I/O registers are in the core well. They are exposed only when CC.SCC is 01h (i.e. IDE programming interface). These are Index/Data Pair registers that are used to access the SerialATA superset registers (SerialATA Status, SerialATA Control and SerialATA Error). The I/O space for these registers is allocated through SIDPBA. Locations with offset from 08h to 0Fh are reserved for future expansion. Software write operations to the reserved locations shall have no effect while software read operations to the reserved locations shall return 0. Refer to Serial ATA Index/Data Pair Superset Registers for more details.

Access Method

Type: I/O Register
(Size: 32 bits)

SDATA: [ABAR] + 4h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

DATA

Bit Range	Default & Access	Description
31:0	00000000h RW	Data (DATA): This Data register is a window through which data is read or written to from the register pointed to by the Serial ATA Index (SINDX) register above. Note that a physical register is not actually implemented as the data is actually stored in the memory mapped registers. Since this is not a physical register, the default value is the same as the default value of the register pointed to by SINDX.RIDX field.

17.8 SATA AHCI Memory Mapped IO Registers

Table 196. Summary of SATA AHCI Memory Mapped I/O Registers—ABAR

Offset	Size	Register ID—Description	Default Value
0h	4	"HBA Capabilities (GHC_CAP)—Offset 0h" on page 1970	DF20FF02h

580h	4	"Enclosure Management Message Format (EM_MF)—Offset 580h" on page 2004	00000000h
584h	4	"Enclosure Management LED (EM_LED)—Offset 584h" on page 2005	00000000h

17.8.1 HBA Capabilities (GHC_CAP)—Offset 0h

This register indicates basic capabilities of the HBA to driver software. The RWO bits in this register are only cleared upon Backbone Reset.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

GHC_CAP: [ABAR] + 0h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: DF20FF02h

31	28	24	20	16	12	8	4	0

								SAM
								SMP
								FBSS
								PMD
								SSC
								PSC
								NCS
								CCCS
								EMS
								SXS
								NP

Bit Range	Default & Access	Description
31	1h RW/O	Supports 64-bit Addressing (S64A): Indicates the S-ATA controller can access 64-bit data structures. The 32-bit upper bits of the port DMA Descriptor, the PRD Base, and each PRD entry are read/write.
30	1h RW/O	Supports Native Command Queuing Acceleration (SCQA): Indicates the SATA controller supports Serial-ATA Native Command Queuing. The HBA will handle DMA Setup FISes in hardware, including support for auto-activate optimization through the FIS.
29	0h RO	Supports SNotification Register (SSNTF): When set to 1, indicates that the HBA supports the PxSNTF (SNotification) register and its associated functionality. When cleared to 0, the HBA does not support the PxSNTF (SNotification) register and its associated functionality.
28	1h RW/O	Supports Mechanical Presence Switch (SMPS): When set to 1, the HBA supports mechanical presence switches on its ports for use in hot plug operations. When cleared to 0, this function is not supported. This value is loaded by the BIOS prior to OS initialization.
27	1h RW/O	Supports Staggered Spin-up (SSS): Indicates whether the S-ATA controller supports staggered spin-up on its ports, for use in balancing power spikes. This value is loaded by platform BIOS prior to OS initialization.
26	1h RW/O	Supports Aggressive Link Power Management (SALP): Indicates the S-ATA controller supports auto-generating link requests to the partial or slumber states when there are no commands to process. When cleared to 0, software shall treat the PxCMD.ALPE and PxCMD.ASP bits as reserved.

Bit Range	Default & Access	Description
25	1h RW/O	Supports Activity LED (SAL): Indicates the S-ATA controller supports a single output pin (SATALED#) which indicates activity.
24	1h RW/O	Supports Command List Override (SCLO): When set to 1, indicates that the HBA supports the PxCMD.CLO bit and its associated function. When cleared to 0, The HBA is not capable of clearing the BSY and DRQ bits in the Status register in order to issue software reset if these bits are still set from a previous operation.
23:20	2h RW/O	Interface Speed Support (ISS): Indicates the maximum speed the S-ATA controller can support on its ports. These encodings match the system software programmable PxSCTL.DET.SPD field. 0000 = Reserved; 0001 = Gen 1 (1.5 Gbps); 0010 = Gen 2 (3 Gbps); 0011 = Gen 3 (6 Gbps); 0100 - 1111 = Reserved.
19	0h RO	Supports Non-Zero DMA Offsets (SNZO): Reserved as per AHCI 1.3
18	0h RW/O	Supports AHCI mode only (SAM): The SATA controller may optionally support AHCI access mechanism only. A value of 0 indicates that in addition to the native AHCI mechanism (via ABAR), the SATA controller implements a legacy, task-file based register interface such as SFF-8038i. A value of 1 indicates that the SATA controller does not implement a legacy, task-file based register interface.
17	0h RO	Supports Port Multiplier (SMP): Not supported.
16	0h RO	FIS-based Switching Supported (FBSS): Not supported.
15	1h RO	PIO Multiple DRQ Block (PMD): If set to 1, the HBA supports multiple DRQ block data transfers for the PIO command protocol.
14	1h RW/O	Slumber State Capable (SSC): The SATA controller supports the slumber state.
13	1h RW/O	Partial State Capable (PSC): The SATA controller supports the partial state.
12:8	1Fh RO	Number of Command Slots (NCS): 1Fh indicating support for 32 slots.
7	0h RO	Command Completion Coalescing Supported (CCCS): When set to 1, indicates that the HBA supports command completion coalescing. When command completion coalescing is supported, the HBA has implemented the CCC_CTL and the CCC_PORTS global HBA registers. When cleared to 0, indicates that the HBA does not support command completion coalescing and the CCC_CTL and CCC_PORTS global HBA registers are not implemented.
6	0h RO	Enclosure Management Supported (EMS): Not supported
5	0h RW/O	Supports External SATA (SXS): When set to 1, indicates that the HBA has one or more Serial ATA ports that has a signal only connector that is externally accessible. If this bit is set, software may refer to the PxCMD.ESP bit to determine whether a specific port has its signal connector externally accessible as a signal only connector (i.e. power is not part of that connector). When the bit is cleared to 0, indicates that the HBA has no Serial ATA ports that have a signal only connector externally accessible.
4:0	02h RO	Number of Ports (NP): 0's based value indicating the maximum number of ports supported. Note that the number of ports indicated in this field may be more than the number of ports indicated in the PI register. Number of ports shall be dependent on MAP.SC and PCIe/SATA muxing configuration where if ANY of these parameter disable a particular port then that port is disabled and not counted. The maximum number of ports supported by SIP is 2 and the least is 0 (i.e. Function Disable). In the case of 0 port configuration, the value of NP is a don't care (while implementation has it fixed as 07h). Any combination in between is supported by SATA host controller. Indicates the number of supported ports.

17.8.2 Global HBA Control (GHC)—Offset 4h

This register controls various global actions of the HBA.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

GHC: [ABAR] + 4h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: 00000000h

31		28				24				20				16				12				8				4				0	
0		0		0		0		0		0		0		0		0		0		0		0		0		0		0			
AE		RSVD0																								MRSM		IE		HR	

Bit Range	Default & Access	Description
31	0h RW	AHCI Enable (AE): When set, indicates that an AHCI driver is loaded and communication to the HBA shall be via AHCI mechanisms. This can be used by an HBA that supports both legacy mechanisms (such as SFF-8038i) and AHCI to know when the HBA is running under an AHCI driver. When set, software shall only talk to the HBA using AHCI. The HBA will not have to allow command processing via both AHCI and legacy mechanisms. When cleared, software will only communicate with the HBA using legacy mechanisms. Software shall set this bit to 1 before accessing other AHCI registers. Note: The implementation of this bit is dependent upon the value of the CAP.SAM bit. If CAP.SAM is 0, then GHC.AE should be RW and shall have a reset value of 0. If CAP.SAM is 1, then AE shall be read only and shall have a reset value of 1.
30:3	0b RO	RSVD0: Reserved
2	0h RO	MSI Revert to Single Message (MRSM): When set to 1 by hardware, indicates that the HBA requested more than one MSI vector but has reverted to using the first vector only. When this bit is cleared to 0, the HBA has not reverted to single MSI mode (i.e. hardware is already in single MSI mode, software has allocated the number of messages requested, or hardware is sharing interrupt vectors if MC.MME (MC.MMC). The HBA may revert to single MSI mode when the number of vectors allocated by the host is less than the number requested. This bit shall only be set to 1 when the following conditions hold: MC.MSIE = 1 (MSI is enabled); MC.MMC = 0 (multiple messages requested); MC.MME = 0 (more than one message allocated); MC.MME != MC.MMC (messages allocated not equal to number requested). When this bit is set to 1, single MSI mode operation is in use and software is responsible for clearing bits in the IS register to clear interrupts. This bit shall be cleared to 0 by hardware when any of the four conditions stated is false. This bit is also cleared to 0 when MC.MSIE = 1 and MC.MME = 0h. In this case, the hardware has been programmed to use single MSI mode, and is not reverting to that mode. The HBA shall always revert to single MSI mode when the number of vectors allocated by the host is less than the number requested. Value of MRSM is a don't care when GHC.HR=1.
1	0h RW	Interrupt Enable (IE): This global bit enables interrupts from the HBA. When cleared (reset default), all interrupt sources from all ports are disabled. When set, interrupts are enabled.
0	0h RW/1S	HBA Reset (HR): When set by SW, this bit causes an internal reset of the HBA. All state machines that relate to data transfers and native command queuing will return to an idle condition, and all ports will be re-initialized via COMRESET. When the HBA has performed the reset action, it will reset this bit to 0. A software write of 0 will have no effect. For a description on which bits are reset when this bit is set, see the AHCI specification, section 10.3.3.

Bit Range	Default & Access	Description
3	1h RO	Supports RAID Platform ID Reporting (SRPIR): If set to 1, then indicates that the RAID Platform ID is reported via ABAR + C0h. Set to 0 if this ID is not reported via MMIO space.
2:0	0b RO	RSVD1: Reserved

17.8.8 Vendor Specific Capabilities (VS_CAP)—Offset A4h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

VS_CAP: [ABAR] + A4h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: 018002FEh

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	1	0
0	0	0	1	1	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	1	0
1	1	1	1	1	1	1	1	0
PNRRO				RSVD0	MSL			PNMBRE

Bit Range	Default & Access	Description
31:16	0180h RO	PCIe NAND Remapped Register Offset (PNRRO): Specifies the DWORD offset within ABAR as to where the PCIe NAND AHCI BAR register space is remapped. Only valid when PNABRE = 1. This places the start of the PCIe NAND AHCI BAR register space at ABAR + 600h
15:12	0b RO	RSVD0: Reserved
11:1	17Fh RW	Memory Space Limit. (MSL): This field specifies the size of the remapped memory space for the PCIe NAND device. It is a 0-based field. Memory BAR offset from 0 to MSL of the PCIe NAND device are remapped under the integrated AHCI controller memory space. The remapped offset into the AHCI memory space and the value programmed in this field must not exceed the allocated 2k AHCI memory space of the integrated AHCI controller. The reset default of this field is 17Fh (i.e. bit[11:1] = 0010111111b) which specifies the size of the remapped memory space as 384 bytes.
0	0h RW/O	PCIe NAND Memory BAR Remapped Enable (PNMBRE): Set to 1 if a PCIe NAND device is present and remapping of its memory BAR register space is enabled. Cleared to 0 if there is no PCIe NAND device present or the remapping of its memory BAR register space is disabled.

17.8.9 RAID Platform ID (RPID)—Offset C0h

This register is used by the Intel Matrix Storage Manager OROM to match the features supported by the OROM with the platform on which the OROM is executing. This prevents the use of an OROM designed for newer chipsets from being use on older chipsets as this could reduce up-sell potential.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

RPID: [ABAR] + C0h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Bit Range	Default & Access	Description
1	1h RW/O	R1: If set to 1, then RAID1 is enabled
0	1h RW/O	R0: If set to 1, then RAID0 is enabled

17.8.12 Port-Command List Base Address (PxCLB0)—Offset 100h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxCLB0: [ABAR] + 100h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CLB						RSVD0		

Bit Range	Default & Access	Description
31:10	000000h RW	Command List Base Address (CLB): Indicates the 32-bit base for the command list for this port. This base is used when fetching commands to execute. This address must be 1K aligned as indicated by bits 31:10 being read/write. Note that these bits are not reset on a HBA reset.
9:0	0b RO	RSVD0: Reserved

17.8.13 Port-Command List Base Address Upper 32-bits (PxCLBU0)—Offset 104h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxCLBU0: [ABAR] + 104h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: 00000000h

[illegible]

Bit Range	Default & Access	Description
31:0	00000000h RW	Command List Base Address Upper (CLBU): Indicates the upper 32-bits for the command list base address for this port. This base is used when fetching commands to execute. Note that these bits are not reset on a HBA reset.

31				28				24				20				16				12				8				4				0																																																							
0				0				0				0				0				0				0				0				0				0																																																			
CPDS				TFES				HBFS				HBDS				IFS				INFS				RSVD0				OFS				IPMS				PRCS				RSVD1																DMPS				PCS				DPS				UFS				SDBS				DSS				PSS				DHRS			

Bit Range	Default & Access	Description
31	0h RO	Cold Presence Detect Status (CPDS): The SATA controller does not support cold presence detect.
30	0h RW/1C	Task File Error Status (TFES): This bit is set whenever the status register is updated by the device and the error bit (bit 0 of the Status field in the received FIS) is set.
29	0h RW/1C	Host Bus Fatal Error Status (HBFS): Indicates that the HBA encountered a host bus error that it cannot recover from, such as a bad software pointer. In PCI, such an indication would be a target or master abort.
28	0h RW/1C	Host Bus Data Error Status (HBDS): Indicates that the HBA encountered a data error (uncorrectable ECC / parity) when reading from or writing to system memory.
27	0h RW/1C	Interface Fatal Error Status (IFS): Indicates that the HBA encountered an error on the SATA interface which caused the transfer to stop.
26	0h RW/1C	Interface Non-fatal Error Status (INFS): Indicates that the HBA encountered an error on the SATA interface but was able to continue operation.
25	0b RO	RSVD0: Reserved
24	0h RW/1C	Overflow Status (OFS): Indicates that the HBA received more bytes from a device than was specified in the PRD table for the command.
23	0h RW/1C	Incorrect Port Multiplier Status (IPMS): Not supported
22	0h RO	PhyRdy Change Status (PRCS): When set to one indicates the internal PhyRdy signal changed state. This bit reflects the state of PxSERR.DIAG.N. This bit is RO and is only cleared when PxSERR.DIAG.N is cleared.
21:8	0b RO	RSVD1: Reserved
7	0h RW/1C	Device Mechanical Presence Status (DMPS): When set, indicates that a platform mechanical presence switch has been opened or closed, which may lead to a change in the connection state of the device. This bit is only valid in systems that support mechanical presence switch (CAP.SMPS and PxCMD.MPSP are set).
6	0h RO	Port Connect Change Status (PCS): 1=Change in Current Connect Status. 0=No change in Current Connect Status. This bit reflects the state of PxSERR.DIAG.X. This bit is only cleared when PxSERR.DIAG.X is cleared.
5	0h RW/1C	Descriptor Processed (DPS): A PRD with the I. bit set has transferred all of its data.
4	0h RO	Unknown FIS Interrupt (UFS): When set to 1 indicates that an unknown FIS was received and has been copied into system memory. This bit is cleared to 0 by software clearing the PxSERR.DIAG.F bit to 0. Note that this bit does not directly reflect the PxSERR.DIAG.F bit. PxSERR.DIAG.F is set immediately when an unknown FIS is detected, whereas this bit is set when the FIS is posted to memory. Software should wait to act on an unknown FIS until this bit is set to 1 or the two bits may become out of sync.
3	0h RW/1C	Set Device Bits Interrupt (SDBS): A Set Device Bits FIS has been received with the I. bit set and has been copied into system memory.
2	0h RW/1C	DMA Setup FIS Interrupt (DSS): A DMA Setup FIS has been received with the I. bit set and has been copied into system memory.

Bit Range	Default & Access	Description
1	0h RW/1C	PIO Setup FIS Interrupt (PSS): A PIO Setup FIS has been received with the I. bit set, it has been copied into system memory, and the data related to that FIS has been transferred. This bit shall be set even if the data transfer resulted in an error.
0	0h RW/1C	Device to Host Register FIS Interrupt (DHRS): A D2H register FIS has been received with the I. bit set, and has been copied into system memory.

17.8.17 Port-Interrupt Enable (PxIE0)—Offset 114h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxIE0: [ABAR] + 114h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

24	0h RW	Overflow Enable (OFE): When set, and GHC.IE and P0IS.OFS are set, the HBA shall generate an interrupt.
23	0h RW	Incorrect Port Multiplier Enable (IPME): When set, and GHC.IE and P0IS.IPMS are set, the HBA shall generate an interrupt.
22	0h RW	PhyRdy Change Interrupt Enable (PRCE): When set, and GHC.IE is set, and PxIS.PRCS is set, the HBA shall generate an interrupt.
21:8	0b RO	RSVD1: Reserved
7	0h RW	Device Mechanical Enable (DMPE): When set, and P0IS.DMPS is set, the HBA shall generate an interrupt.

Bit Range	Default & Access	Description
6	0h RW	Port Change Interrupt Enable (PCE): When set, GHC.IE is set, and P0IS.PCS is set, the HBA shall generate an interrupt.
5	0h RW	Descriptor Processed Interrupt Enable (DPE): When set, GHC.IE is set, and P0IS.DPS is set, the HBA shall generate an interrupt.
4	0h RW	Unknown FIS Interrupt Enable (UFE): When set, GHC.IE is set, and PxIS.UFS is set to 1, the HBA shall generate an interrupt.
3	0h RW	Set Device Bits FIS Interrupt Enable (SDBE): When set, GHC.IE is set, and P0IS.SDBS is set, the HBA shall generate an interrupt.
2	0h RW	DMA Setup FIS Interrupt Enable (DSE): When set, GHC.IE is set, and P0IS.DSS is set, the HBA shall generate an interrupt.
1	0h RW	PIO Setup FIS Interrupt Enable (PSE): When set, GHC.IE is set, and P0IS.PSS is set, the HBA shall generate an interrupt.
0	0h RW	Device to Host Register FIS Interrupt Enable (DHRE): When set, GHC.IE is set, and P0IS.DHRS is set, the HBA shall generate an interrupt.

17.8.18 Port-Command (PxCMD0)—Offset 118h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxCMD0: [ABAR] + 118h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: 00000004h

31				28				24				20				16				12				8				4				0	
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0			
ICC				ASP	ALPE			DLAE	ATAPI	APSTE	FBSCP	ESP	CPD	MPSP	HPCP	PMA	RSVD0	CR	FR	MPSS	CCS				RSVD1	PSP	APSE	FRE	CLO	POD	SUD	ST	

Bit Range	Default & Access	Description
31:28	0h RW	Interface Communication Control (ICC): This is a four bit field which can be used to control reset and power states of the interface. If the Link layer is currently in the L_IDLE state, writes to this field shall cause the HBA to initiate a transition to the interface power management state requested. If the Link layer is not currently in the L_IDLE state, writes to this field shall have no effect. Fh -9h Reserved. 8h DEVSLP: This shall cause the HBA to assert the DEVSLP signal associated with the port; the HBA shall ignore the DEVSLP Idle Timeout value specified by PxDEVSLP.DITO. Software shall only request DEVSLP when the interface is in an idle state (i.e. PxCI is cleared to 0h and PxSACT is cleared to 0h); if the interface is not idle at the time the register is written, then the HBA takes no action and the interface remains in its current state. If PxCAP2.DESO is set to '1' and PxSSTS.IPM is not set to '6h', then the HBA takes no action and the interface remains in its current state. Additionally, the HBA shall not assert the DEVSLP signal until PHYRDY has been achieved (after a previous de-assertion). 7h Reserved 6h Slumber: This shall cause the HBA to request a transition of the interface to the Slumber state. The SATA device may reject the request and the interface shall remain in its current state. 5h-3h Reserved. 2h Partial: This shall cause the HBA to request a transition of the interface to the Partial state. The SATA device may reject the request and the interface shall remain in its current state. 1h Active: This shall cause the HBA to request a transition of the interface into the active state. If the requested transition is from the DEVSLP state, then the HBA shall wait until PxDEVSLP.DMAT has expired before de-asserting the DEVSLP signal. 0h No-Op / Idle: When software reads this value, it indicates the HBA is ready to accept a new interface control command, although the transition to the previously selected state may not yet have occurred. When system software writes a non-reserved value other than No-Op (0h), the HBA shall perform the action and update this field back to Idle (0h). If software writes to this field to change the state to a state the link is already in (i.e. interface is in the active state and a request is made to go to the active state), the HBA shall take no action and return this field to Idle. If the interface is in a low power state and the software wants to transition to a different low power state, software must first bring the link to active and then initiate the transition to the desired low power state (with the exception of DEVSLP). The transition to DEVSLP may occur from any other state if CAP2.DESO is cleared to '0'. If CAP2.DESO is set to '1', then DEVSLP may only be transitioned to if the link is in Slumber.
27	0h RW	Aggressive Slumber Partial (ASP): When set to 1, and the ALPE bit is set, the HBA shall aggressively enter Slumber state when it clears a bit in the PxCI or PxSACT register and the register values are 0h. When cleared, and the ALPE bit is set, the HBA will aggressively enter Partial state when it clears a bit in the PxCI or PxSACT register and the register values are both 0h. If CAP.SALP is cleared to 0, software shall treat this bit as reserved.
26	0h RW	Aggressive Link Power Management Enable (ALPE): When set, the HBA will aggressively enter a lower link power state (Partial or Slumber) based upon the setting of the ASP bit.
25	0h RW	Drive LED on ATAPI Enable (DLAE): When set, the HBA will drive the LED pin active for commands regardless of the state of PxCMD.ATAPI. When cleared, the HBA will only drive the LED pin active for commands if PxCMD.ATAPI is set to 0. This bit is set by software

Bit Range	Default & Access	Description
24	0h RW	Device is ATAPI (ATAPI): When set, the connected device is an ATAPI device. This bit is used by the HBA to control whether or not to generate the desktop LED when commands are active.
23	0h RW	Automatic Partial to Slumber Transitions Enabled (APSTE): When set to 1, the HBA may perform Automatic Partial to Slumber Transitions. When cleared to 0 - the port shall not perform Automatic Partial to Slumber Transitions. Software shall only set this bit to 1 - if CAP2.APST is set to 1; if CAP2.APST is cleared to 0 - software shall treat this bit as reserved.
22	0h RO	FIS-based Switching Capable Port (FBSCP): The SATA controller does not support FIS-Based Switching.
21	0h RW/O	External SATA Port (ESP): When set to 1, indicates that this port is routed externally and will be used with an external SATA device. When set to 1, CAP.SXS must also be set to 1. When cleared (0), indicates that this port is not routed externally and supports internal SATA devices only. If ESP is set to 1, then the port may experience hot plug events.
20	0h RO	Cold Presence Detection (CPD): The SATA controller does not support cold presence detect.
19	0h RW/O	Mechanical Presence Switch Attached to Port (MPSP): If set to 1, the platform supports a mechanical presence switch attached to this port. If cleared to 0, the platform does not support a mechanical presence switch attached to this port.
18	0h RW/O	Hot Plug Capable Port (HPCP): This indicates whether this port is connected to a device which can be hot plugged. SATA by definition is hot-pluggable, but not all platforms are constructed to allow the device to be removed (it may be screwed into the chassis, for example). This bit can be used by system software to indicate a feature such as eject device to the end-user.
17	0h RO	Port Multiplier Attached (PMA): Not supported
16	0b RO	RSVD0: Reserved
15	0h RO	Command List Running (CR): When this bit is set it indicates that the command list DMA engine for the port is running.
14	0h RO	FIS Receive Running (FR): When this bit is set it indicates that the FIS Receive DMA engine for the port is running.
13	0h RO	Mechanical Presence Switch State (MPSS): The MPSS bit reports the state of a mechanical presence switch attached to this port. If CAP.SMPS is set to 1 and the mechanical presence switch is closed then this bit is cleared to 0. If CAP.SMPS is set to 1 and the mechanical presence switch is open then this bit is set to 1. If CAP.SMPS is set to 0 then this bit is cleared to 0. Software should only use this bit if both CAP.SMPS and PxCMD.MPSP are set to 1.
12:8	00h RO	Current Command Slot (CCS): Indicates the current command slot the HBA is processing. This field is valid when the PxCMD.ST bit is set, and is constantly updated by the HBA. This field can be updated as soon as the HBA recognizes an active command slot, or at some point soon after when it begins processing the command. When PxCMD.ST transitions from a 1 to a 0, the HBA will reset this field to 0. After PxCMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command has been issued, the highest priority slot to issue from next is PxCMD.CCS + 1. For example, after the HBA has issued its first command, if PxCMD.CCS = 0h and PxCI is set to 3h, the next command that will be issued is from command slot 1.
7	0b RO	RSVD1: Reserved
6	0h RO	PHYSLP Present (PSP): If set to 1, the platform supports PHYSLP on this port. If cleared to 0, the platform does not support PHYSLP on this port. This bit may only be set to 1 if CAP2.SPS is set to 1.

17.8.19 Port-Task File Data (PxTFD0)—Offset 120h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxTFD0: [ABAR] + 120h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: 0000007Fh

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RSVD0				ERR				STS_BSY
								STS_RSVD0
								STS_DRQ
								STS_RSVD1
								STS_FRR

Bit Range	Default & Access	Description
31:16	0b RO	RSVDD0: Reserved
15:8	00h RO	Error (ERR): Contains the latest copy of the task file error register.

Bit Range	Default & Access	Description
11:8	0h RO	Interface Power Management (IPM): Indicates the current interface state. 0h = Device not present or communication not established. 1h = Interface in active state. 2h = Interface in PARTIAL power management state. 6h = Interface in SLUMBER power management state. 8h = PHYSLP asserted. All other values reserved. This field reflects the interface power management state for both device and host initiated power management. Note: If an automatic partial to slumber transition occurs, PxSSTS.IPM shall reflect that the host has entered slumber (PxSSTS.IPM = 6h.)
7:4	0h RO	Current Interface Speed (SPD): Indicates the negotiated interface communication speed. 0h = Device not present or communication not established. 1h = Generation 1 communication rate negotiated. 2h = Generation 2 communication rate negotiated. 3h = Generation 3 communication rate negotiated. All other values reserved
3:0	0h RO	Device Detection (DET): Indicates the interface device detection and Phy state. 0h = No device detected and Phy communication not established. 1h = Device presence detected but Phy communication not established. 3h = Device presence detected and Phy communication established. 4h = Phy in offline mode as a result of the interface being disabled or running in a BIST loopback mode. All other values reserved. Note that, while the true reset default value of this register is 0h, the value read from this register depends on drive presence and the point in time within the initialization process when the register is read. Note: The means by which the implementation determines device presence may be vendor specific. However, device presence shall always be indicated anytime a COMINIT signal is received.

17.8.22 Port-Serial ATA Control (PxSCTL0)—Offset 12Ch

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxSCTL0: [ABAR] + 12Ch

19:16	0h RW	Port Multiplier Port (PMP): This field is not used by AHCI.
15:12	0h RW	Select Power Management (SPM): This field is not used by AHCI.
11:8	0h RW	Interface Power Management Transitions Allowed (IPM): Indicates which power states the HBA is allowed to transition to. If an interface power management state is not allowed via this register field, the HBA will not initiate that state and the HBA will PMNAKP any request from the device to enter that state. 0h No interface restrictions 1h Transitions to the PARTIAL state disabled 2h Transitions to the SLUMBER state disabled 3h Transitions to both PARTIAL and SLUMBER states disabled 4h Transitions to the DEVSLP power management state are disabled 5h Transitions to the Partial and DEVSLP power management states are disabled 6h Transitions to the Slumber and DEVSLP power management states are disabled 7h Transitions to the Partial, Slumber and DEVSLP power management states are disabled All other values reserved

Bit Range	Default & Access	Description
15:0	0000h RW/1C	Error (ERR): The ERR field contains error information for use by host software in determining the appropriate response to the error condition. If one or more of bits 11:8 of this register are set, the controller will stop the current transfer. 15:12 Reserved 11 Internal Error (E): The SATA controller failed due to a master or target abort when attempting to access system memory. 10 Protocol Error (P): A violation of the Serial ATA protocol was detected. 9 Persistent Communication or Data Integrity Error (C): A communication error that was not recovered occurred that is expected to be persistent. Persistent communications errors may arise from faulty interconnect with the device, from a device that has been removed or has failed, or a number of other causes. 8 Transient Data Integrity Error (T): A data integrity error occurred that was not recovered by the interface. 7:2 Reserved 1 Recovered Communications Error (M): Communications between the device and host was temporarily lost but was re-established. This can arise from a device temporarily being removed, from a temporary loss of Phy synchronization, or from other causes and may be derived from the PhyNRdy signal between the Phy and Link layers. 0 Recovered Data Integrity Error (I): A data integrity error occurred that was recovered by the interface through a retry operation or other recovery action.

17.8.24 Port-Serial ATA Active (PxSACT0)—Offset 134h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxSACT0: [ABAR] + 134h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0

Bit Range	Default & Access	Description
31:0	00000000h RW/1S	Device Status (DS): System software sets this bit for native command queuing commands prior to setting the PxCI.CI bit in the same command slot entry. This field is cleared via the Set Device Bits FIS.

17.8.25 Port-Commands Issued (PxCI0)—Offset 138h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxCI0: [ABAR] + 138h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

0	0	0	1	1	1	0	0	0	0	0	0	0	1	0
RSVD0	DM	DITO				MDAT	DETO			DSP	ADSE			

Bit Range	Default & Access	Description
31:29	0b RO	RSVD0: Reserved
28:25	Fh RW/O	DITO Multiplier (DM): 0's based value that specifies the DITO multiplier that the HBA applies to the specified DITO value, effectively extending the range of DITO from 1ms to 16368ms. A value of 0h indicates a multiplier of 1. A maximum multiplier of 16 may be applied. The HBA computes the total idle timeout as a product of DM and DITO (i.e. DITO actual = DITO * DM).
24:15	004h RW	DEVSLP Idle Timeout (DITO): This field specifies the amount of the time (in approximate 1ms granularity) that the HBA shall wait before driving the DEVSLP signal.
14:10	0Ah RW	DEVSLP Minimum Assertion Time (MDAT): This field specifies the minimum amount of time (in 1ms granularity) that the HBA must assert the DEVSLP signal before it may be de-asserted. The nominal value is 10ms and the minimum is 1ms depending on device identification information.
9:2	14h RW	DEVSLP Exit Timeout (DETO): This field specifies the maximum duration (in approximate 1ms granularity) from DEVSLP de-assertion until the device is ready to accept OOB. The nominal value is 20ms while the max value is 255ms depending on device identification information.
1	1h RW/O	DEVSLP Present (DSP): If set to 1, the platform supports DEVSLP on this port. If cleared to 0, the platform does not support DEVSLP on this port.
0	0h RW	Aggressive DEVSLP Enable (ADSE): When this bit is cleared to 0, the HBA does not enter DEVSLP unless software directed via PxCMD.ICC. This bit shall only be set to 1 if PxDEVSLP.DSP is set to 1. If this bit is set to 1 and software clears the bit to 0, then the HBA shall de-assert the DEVSLP signal if asserted.

Bit Range	Default & Access	Description
31	0h RO	Cold Presence Detect Status (CPDS): The SATA controller does not support cold presence detect.
30	0h RW/1C	Task File Error Status (TFES): This bit is set whenever the status register is updated by the device and the error bit (bit 0 of the Status field in the received FIS) is set.
29	0h RW/1C	Host Bus Fatal Error Status (HBFS): Indicates that the HBA encountered a host bus error that it cannot recover from, such as a bad software pointer. In PCI, such an indication would be a target or master abort.
28	0h RW/1C	Host Bus Data Error Status (HBDS): Indicates that the HBA encountered a data error (uncorrectable ECC / parity) when reading from or writing to system memory.
27	0h RW/1C	Interface Fatal Error Status (IFS): Indicates that the HBA encountered an error on the SATA interface which caused the transfer to stop.
26	0h RW/1C	Interface Non-fatal Error Status (INFS): Indicates that the HBA encountered an error on the SATA interface but was able to continue operation.
25	0b RO	RSVD0: Reserved
24	0h RW/1C	Overflow Status (OFS): Indicates that the HBA received more bytes from a device than was specified in the PRD table for the command.
23	0h RW/1C	Incorrect Port Multiplier Status (IPMS): Not supported
22	0h RO	PhyRdy Change Status (PRCS): When set to one indicates the internal PhyRdy signal changed state. This bit reflects the state of PxSERR.DIAG.N. This bit is RO and is only cleared when PxSERR.DIAG.N is cleared.
21:8	0b RO	RSVD1: Reserved
7	0h RW/1C	Device Mechanical Presence Status (DMPS): When set, indicates that a platform mechanical presence switch has been opened or closed, which may lead to a change in the connection state of the device. This bit is only valid in systems that support mechanical presence switch (CAP.SMPS and PxCMD.MPSP are set).
6	0h RO	Port Connect Change Status (PCS): 1=Change in Current Connect Status. 0=No change in Current Connect Status. This bit reflects the state of PxSERR.DIAG.X. This bit is only cleared when PxSERR.DIAG.X is cleared.
5	0h RW/1C	Descriptor Processed (DPS): A PRD with the I. bit set has transferred all of its data.
4	0h RO	Unknown FIS Interrupt (UFS): When set to 1 indicates that an unknown FIS was received and has been copied into system memory. This bit is cleared to 0 by software clearing the PxSERR.DIAG.F bit to 0. Note that this bit does not directly reflect the PxSERR.DIAG.F bit. PxSERR.DIAG.F is set immediately when an unknown FIS is detected, whereas this bit is set when the FIS is posted to memory. Software should wait to act on an unknown FIS until this bit is set to 1 or the two bits may become out of sync.
3	0h RW/1C	Set Device Bits Interrupt (SDBS): A Set Device Bits FIS has been received with the I. bit set and has been copied into system memory.
2	0h RW/1C	DMA Setup FIS Interrupt (DSS): A DMA Setup FIS has been received with the I. bit set and has been copied into system memory.
1	0h RW/1C	PIO Setup FIS Interrupt (PSS): A PIO Setup FIS has been received with the I. bit set, it has been copied into system memory, and the data related to that FIS has been transferred. This bit shall be set even if the data transfer resulted in an error.
0	0h RW/1C	Device to Host Register FIS Interrupt (DHRS): A D2H register FIS has been received with the I. bit set, and has been copied into system memory.

17.8.32 Port-Interrupt Enable (PxIE1)—Offset 194h

Access Method

Bit Range	Default & Access	Description
31:28	0h RW	Interface Communication Control (ICC): This is a four bit field which can be used to control reset and power states of the interface. If the Link layer is currently in the L_IDLE state, writes to this field shall cause the HBA to initiate a transition to the interface power management state requested. If the Link layer is not currently in the L_IDLE state, writes to this field shall have no effect. Fh -9h Reserved. 8h DEVSLP: This shall cause the HBA to assert the DEVSLP signal associated with the port; the HBA shall ignore the DEVSLP Idle Timeout value specified by PxDEVSLP.DITO. Software shall only request DEVSLP when the interface is in an idle state (i.e. PxCI is cleared to 0h and PxSACT is cleared to 0h); if the interface is not idle at the time the register is written, then the HBA takes no action and the interface remains in its current state. If PxCAP2.DESO is set to '1' and PxSSTS.IPM is not set to '6h', then the HBA takes no action and the interface remains in its current state. Additionally, the HBA shall not assert the DEVSLP signal until PHYRDY has been achieved (after a previous de-assertion). 7h Reserved 6h Slumber: This shall cause the HBA to request a transition of the interface to the Slumber state. The SATA device may reject the request and the interface shall remain in its current state. 5h-3h Reserved. 2h Partial: This shall cause the HBA to request a transition of the interface to the Partial state. The SATA device may reject the request and the interface shall remain in its current state. 1h Active: This shall cause the HBA to request a transition of the interface into the active state. If the requested transition is from the DEVSLP state, then the HBA shall wait until PxDEVSLP.DMAT has expired before de-asserting the DEVSLP signal. 0h No-Op / Idle: When software reads this value, it indicates the HBA is ready to accept a new interface control command, although the transition to the previously selected state may not yet have occurred. When system software writes a non-reserved value other than No-Op (0h), the HBA shall perform the action and update this field back to Idle (0h). If software writes to this field to change the state to a state the link is already in (i.e. interface is in the active state and a request is made to go to the active state), the HBA shall take no action and return this field to Idle. If the interface is in a low power state and the software wants to transition to a different low power state, software must first bring the link to active and then initiate the transition to the desired low power state (with the exception of DEVSLP). The transition to DEVSLP may occur from any other state if CAP2.DESO is cleared to '0'. If CAP2.DESO is set to '1', then DEVSLP may only be transitioned to if the link is in Slumber.

Bit Range	Default & Access	Description
27	0h RW	Aggressive Slumber Partial (ASP): When set to 1, and the ALPE bit is set, the HBA shall aggressively enter Slumber state when it clears a bit in the PxCI or PxSACT register and the register values are 0h. When cleared, and the ALPE bit is set, the HBA will aggressively enter Partial state when it clears a bit in the PxCI or PxSACT register and the register values are both 0h. If CAP.SALP is cleared to 0, software shall treat this bit as reserved.
26	0h RW	Aggressive Link Power Management Enable (ALPE): When set, the HBA will aggressively enter a lower link power state (Partial or Slumber) based upon the setting of the ASP bit.
25	0h RW	Drive LED on ATAPI Enable (DLAE): When set, the HBA will drive the LED pin active for commands regardless of the state of PxCMD.ATAPI. When cleared, the HBA will only drive the LED pin active for commands if PxCMD.ATAPI is set to 0. This bit is set by software
24	0h RW	Device is ATAPI (ATAPI): When set, the connected device is an ATAPI device. This bit is used by the HBA to control whether or not to generate the desktop LED when commands are active.
23	0h RW	Automatic Partial to Slumber Transitions Enabled (APSTE): When set to 1, the HBA may perform Automatic Partial to Slumber Transitions. When cleared to 0 - the port shall not perform Automatic Partial to Slumber Transitions. Software shall only set this bit to 1 - if CAP2.APST is set to 1; if CAP2.APST is cleared to 0 - software shall treat this bit as reserved.
22	0h RO	FIS-based Switching Capable Port (FBSCP): The SATA controller does not support FIS-Based Switching.
21	0h RW/O	External SATA Port (ESP): When set to 1, indicates that this port is routed externally and will be used with an external SATA device. When set to 1, CAP.SXS must also be set to 1. When cleared (0), indicates that this port is not routed externally and supports internal SATA devices only. If ESP is set to 1, then the port may experience hot plug events.
20	0h RO	Cold Presence Detection (CPD): The SATA controller does not support cold presence detect.
19	0h RW/O	Mechanical Presence Switch Attached to Port (MPSP): If set to 1, the platform supports a mechanical presence switch attached to this port. If cleared to 0, the platform does not support a mechanical presence switch attached to this port.
18	0h RW/O	Hot Plug Capable Port (HPCP): This indicates whether this port is connected to a device which can be hot plugged. SATA by definition is hot-pluggable, but not all platforms are constructed to allow the device to be removed (it may be screwed into the chassis, for example). This bit can be used by system software to indicate a feature such as eject device to the end-user.
17	0h RO	Port Multiplier Attached (PMA): Not supported
16	0b RO	RSVD0: Reserved
15	0h RO	Command List Running (CR): When this bit is set it indicates that the command list DMA engine for the port is running.
14	0h RO	FIS Receive Running (FR): When this bit is set it indicates that the FIS Receive DMA engine for the port is running.
13	0h RO	Mechanical Presence Switch State (MPSS): The MPSS bit reports the state of a mechanical presence switch attached to this port. If CAP.SMPS is set to 1 and the mechanical presence switch is closed then this bit is cleared to 0. If CAP.SMPS is set to 1 and the mechanical presence switch is open then this bit is set to 1. If CAP.SMPS is set to 0 then this bit is cleared to 0. Software should only use this bit if both CAP.SMPS and PxCMD.MPSP are set to 1.

Bit Range	Default & Access	Description
12:8	00h RO	Current Command Slot (CCS): Indicates the current command slot the HBA is processing. This field is valid when the PxCMD.ST bit is set, and is constantly updated by the HBA. This field can be updated as soon as the HBA recognizes an active command slot, or at some point soon after when it begins processing the command. When PxCMD.ST transitions from a 1 to a 0, the HBA will reset this field to 0. After PxCMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command has been issued, the highest priority slot to issue from next is PxCMD.CCS + 1. For example, after the HBA has issued its first command, if PxCMD.CCS = 0h and PxCI is set to 3h, the next command that will be issued is from command slot 1.
7	0b RO	RSVD1: Reserved
6	0h RO	PHYSLP Present (PSP): If set to 1, the platform supports PHYSLP on this port. If cleared to 0, the platform does not support PHYSLP on this port. This bit may only be set to 1 if CAP2.SPS is set to 1.
5	0h RW	Aggressive PHYSLP Enable (APSE): This bit is read/write for HBAs that support aggressive PHYSLP management (CAP2.SAPM == 1). This bit is read-only for HBAs that do not support aggressive PHYSLP management (CAP2.SPS == 0). When this bit is set to 1, the HBA shall assert the PHYSLP signal after the port has been idle (PxCI == 0h and PxSACT == 0h) for the amount of time specified by the GHC.PITO register. When this bit is cleared to 0, the HBA does not enter PHYSLP unless software directed via PxCMD.ICC. This bit shall only be set to 1 if PxCMD.PSP is set to 1. If this bit is set to 1 and software clears the bit to 0, then the HBA shall de-assert the PHYSLP signal if asserted.
4	0h RW	FIS Receive Enable (FRE): When set, the HBA may post received FISes into the FIS receive area pointed to by PxFB and PxFBU. When cleared, received FISes are not accepted by the HBA, except for the first D2H register FIS after the initialization sequence.
3	0h RW/1S	Command List Override (CLO): Setting this bit to 1 causes PxTFD.STS.BSY and PxTFD.STS.DRQ to be cleared to 0. This allows a software reset to be transmitted to the device regardless of whether the BSY and DRQ bits are still set in the PxTFD.STS register. The HBA sets this bit to 0 when PxTFD.STS.BSY and PxTFD.STS.DRQ have been cleared to 0. A write to this register with a value of 0 shall have no effect.
2	1h RO	Power On Device (POD): The SATA controller does not support cold presence detect.
1	0h RW	Spin-Up Device (SUD): This bit is read/write for HBAs that support staggered spin-up via CAP.SSS. This bit is read only 1 for HBAs that do not support staggered spin-up. On an edge detect from 0 to 1, the HBA shall start a COMRESET initialization sequence to the device. Clearing this bit causes no action on the interface. Clearing this bit to 0 does not cause any OOB signal to be sent on the interface. When this bit is cleared to 0 and PxSCTL.DET = 0h, the HBA will enter listen mode.
0	0h RW	Start (ST): When set, the HBA may process the command list. When cleared, the HBA may not process the command list. Whenever this bit is changed from a 0 to a 1, the HBA starts processing the command list at entry 0. Whenever this bit is changed from a 1 to a 0, the PxCI and PxSACT register is cleared by the HBA upon the HBA putting the controller into an idle state. PxTFD shall be updated also.

17.8.36 Port-Serial ATA Status (PxSSTS1)—Offset 1A8h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxSSTS1: [ABAR] + 1A8h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RSVD0						IPM	SPD	DET

Bit Range	Default & Access	Description
31:12	0b RO	RSVD0: Reserved
11:8	0h RO	Interface Power Management (IPM): Indicates the current interface state 0h = Device not present or communication not established. 1h = Interface in active state. 2h = Interface in PARTIAL power management state. 6h = Interface in SLUMBER power management state. 8h = PHYSLP asserted. All other values reserved. This field reflects the interface power management state for both device and host initiated power management. Note: If an automatic partial to slumber transition occurs, PxSSTS.IPM shall reflect that the host has entered slumber (PxSSTS.IPM = 6h.)
7:4	0h RO	Current Interface Speed (SPD): Indicates the negotiated interface communication speed. 0h = Device not present or communication not established. 1h = Generation 1 communication rate negotiated. 2h = Generation 2 communication rate negotiated. 3h = Generation 3 communication rate negotiated. All other values reserved
3:0	0h RO	Device Detection (DET): Indicates the interface device detection and Phy state. 0h = No device detected and Phy communication not established. 1h = Device presence detected but Phy communication not established. 3h = Device presence detected and Phy communication established. 4h = Phy in offline mode as a result of the interface being disabled or running in a BIST loopback mode. All other values reserved. Note that, while the true reset default value of this register is 0h, the value read from this register depends on drive presence and the point in time within the initialization process when the register is read. Note: The means by which the implementation determines device presence may be vendor specific. However, device presence shall always be indicated anytime a COMINIT signal is received.

17.8.37 Port-Serial ATA Control (PxSCTL1)—Offset 1ACh

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxSCTL1: [ABAR] + 1ACh

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
		RSVD0		PMP	SPM	IPM	SPD	DET

Bit Range	Default & Access	Description
31:20	0b RO	RSVD0: Reserved
19:16	0h RW	Port Multiplier Port (PMP): This field is not used by AHCI.
15:12	0h RW	Select Power Management (SPM): This field is not used by AHCI.
11:8	0h RW	Interface Power Management Transitions Allowed (IPM): Indicates which power states the HBA is allowed to transition to. If an interface power management state is not allowed via this register field, the HBA will not initiate that state and the HBA will PMNAKP any request from the device to enter that state. 0h No interface restrictions 1h Transitions to the PARTIAL state disabled 2h Transitions to the SLUMBER state disabled 3h Transitions to both PARTIAL and SLUMBER states disabled 4h Transitions to the DEVSLP power management state are disabled 5h Transitions to the Partial and DEVSLP power management states are disabled 6h Transitions to the Slumber and DEVSLP power management states are disabled 7h Transitions to the Partial, Slumber and DEVSLP power management states are disabled All other values reserved
7:4	0h RW	Speed Allowed (SPD): Indicates the highest allowable speed of the interface. 0h No speed negotiation restrictions. 1h Limit speed negotiation to Generation 1 communication rate. 2h Limit speed negotiation to a rate not greater than Generation 2 communication rate. 3h Limit speed negotiation to a rate not greater than Generation 3 communication rate. All other values reserved. Note: If software changes SPD after port has been enabled, software is required to perform a port reset via DET=1h.
3:0	0h RW	Device Detection Initialization (DET): Controls HBA's device detection and interface initialization. 0h No device detection or initialization action requested. 1h Perform interface communication initialization sequence to establish communication. This is functionally equivalent to a hard reset and results in the interface being reset and communications reinitialized. While this field is 1h, COMRESET is continuously transmitted on the interface. Software should leave the DET field set to 1h for a minimum of 1 millisecond to ensure that a COMRESET is sent on the interface. 4h Disable the Serial ATA interface and put Phy in offline mode. All other values reserved. This field may only be changed when PxCMD.ST is '0'. Changing this field while the HBA is running results in undefined behavior. When PxCMD.ST is set to '1', this field should have a value of 0h. It is permissible to implement any of the Serial ATA defined behaviors for transmission of COMRESET when PxSCTL.DET = 1h

17.8.38 Port-Serial ATA Error (PxSERR1)—Offset 1B0h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxSERR1: [ABAR] + 1B0h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
DIAG				ERR				

Bit Range	Default & Access	Description
31:16	0000h RW/1C	Diagnostics (DIAG): Contains diagnostic error information for use by diagnostic software in validating correct operation or isolating failure modes. Bit Field 31:27 Reserved 26 Exchanged (X): When set to one this bit indicates that a change in device presence has been detected since the last time this bit was cleared. The means by which the implementation determines that the device presence has changed is vendor specific. This bit shall always be set to one anytime a COMINIT signal is received. This bit is reflected in the POIS.PCS bit. 25 Unrecognized FIS Type (F): Indicates that one or more FISs were received by the Transport layer with good CRC, but had a type field that was not recognized. 24 Transport state transition error (T): Indicates that an error has occurred in the transition from one state to another within the Transport layer since the last time this bit was cleared. 23 Link Sequence Error (S): Indicates that one or more Link state machine error conditions were encountered. The Link Layer state machine defines the conditions under which the link layer detects an erroneous transition. 22 Handshake Error (H): Indicates that one or more R_ERR handshake response was received in response to frame transmission. Such errors may be the result of a CRC error detected by the recipient, a disparity or 8b/10b decoding error, or other error condition leading to a negative handshake on a transmitted frame. 21 CRC Error (C): Indicates that one or more CRC errors occurred with the Link Layer. 20 Disparity Error (D): This field is not used by AHCI. 19 10B to 8B Decode Error (B): Indicates that one or more 10B to 8B decoding errors occurred. 18 Comm Wake (W): Indicates that a Comm Wake signal was detected by the Phy. 17 Phy Internal Error (I): Indicates that the Phy detected some internal error. 16 PhyRdy Change (N): When set to 1 this bit indicates that the internal PhyRdy signal changed state since the last time this bit was cleared. The state of this bit is reflected in the PxIS.PRCs interrupt status bit and an interrupt will be generated if enabled.
15:0	0000h RW/1C	Error (ERR): The ERR field contains error information for use by host software in determining the appropriate response to the error condition. If one or more of bits 11:8 of this register are set, the controller will stop the current transfer. 15:12 Reserved 11 Internal Error (E): The SATA controller failed due to a master or target abort when attempting to access system memory. 10 Protocol Error (P): A violation of the Serial ATA protocol was detected. 9 Persistent Communication or Data Integrity Error (C): A communication error that was not recovered occurred that is expected to be persistent. Persistent communications errors may arise from faulty interconnect with the device, from a device that has been removed or has failed, or a number of other causes. 8 Transient Data Integrity Error (T): A data integrity error occurred that was not recovered by the interface. 7:2 Reserved 1 Recovered Communications Error (M): Communications between the device and host was temporarily lost but was re-established. This can arise from a device temporarily being removed, from a temporary loss of Phy synchronization, or from other causes and may be derived from the PhyNRdy signal between the Phy and Link layers. 0 Recovered Data Integrity Error (I): A data integrity error occurred that was recovered by the interface through a retry operation or other recovery action.

17.8.39 Port-Serial ATA Active (PxSACT1)—Offset 1B4h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxSACT1: [ABAR] + 1B4h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0

Bit Range	Default & Access	Description
31:0	00000000h RW	Commands Issued (CI): This field is set by software to indicate to the HBA that a command has been built in system memory for a command slot and may be sent to the device. When the HBA receives a FIS which clears the BSY, ERR, and DRQ bits for the command, it clears the corresponding bit in this register for that command slot. Bits in this field shall only be set to 1 by software when PxCMD.ST is set to 1.

17.8.41 Port-Device Sleep (PxDEVSLP1)—Offset 1C4h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PxDEVSLP1: [ABAR] + 1C4h

ABAR Type: PCI Configuration Register (Size: 32 bits)

ABAR Reference: [B:0, D:19, F:0] + 24h

Default: 1E022852h

31				28				24				20				16				12				8				4				0			
0	0	0	1	1	1	1	0	0	0	0	0	0	0	1	0	0	0	1	0	1	0	0	0	0	1	0	1	0	0	1	0				
RSVD0				DM				DITO								MDAT				DETO								DSP	ADSE						

Bit Range	Default & Access	Description
31:29	0b RO	RSVD0: Reserved
28:25	Fh RW/O	DITO Multiplier (DM): 0's based value that specifies the DITO multiplier that the HBA applies to the specified DITO value, effectively extending the range of DITO from 1ms to 16368ms. A value of 0h indicates a multiplier of 1. A maximum multiplier of 16 may be applied. The HBA computes the total idle timeout as a product of DM and DITO (i.e. DITO actual = DITO * DM).
24:15	004h RW	DEVSLP Idle Timeout (DITO): This field specifies the amount of the time (in approximate 1ms granularity) that the HBA shall wait before driving the DEVSLP signal.
14:10	0Ah RW	DEVSLP Minimum Assertion Time (MDAT): This field specifies the minimum amount of time (in 1ms granularity) that the HBA must assert the DEVSLP signal before it may be de-asserted. The nominal value is 10ms and the minimum is 1ms depending on device identification information.
9:2	14h RW	DEVSLP Exit Timeout (DETO): This field specifies the maximum duration (in approximate 1ms granularity) from DEVSLP de-assertion until the device is ready to accept OOB. The nominal value is 20ms while the max value is 255ms depending on device identification information.
1	1h RW/O	DEVSLP Present (DSP): If set to 1, the platform supports DEVSLP on this port. If cleared to 0, the platform does not support DEVSLP on this port.
0	0h RW	Aggressive DEVSLP Enable (ADSE): When this bit is cleared to 0, the HBA does not enter DEVSLP unless software directed via PxCMD.ICC. This bit shall only be set to 1 if PxDEVSLP.DSP is set to 1. If this bit is set to 1 and software clears the bit to 0, then the HBA shall de-assert the DEVSLP signal if asserted.

17.8.42 Enclosure Management Message Format (EM_MF)—Offset 580h

This register is not implemented in VLV.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Bit Range	Default & Access	Description
31:0	0h RO	RSVD: Reserved.

17.9 SATA Primary Read Command IO Registers

Table 197. Summary of SATA Primary Read Command I/O Registers—PCMDIDEBA

Offset	Size	Register ID—Description	Default Value
1h	1	"Primary Channel Error register (P_ERROR)—Offset 1h" on page 2006	00h
2h	1	"Primary Channel Sector Count register (P_SECTOR_COUNT)—Offset 2h" on page 2006	00h
3h	1	"Primary Channel Sector Number register (P_SECTOR_NUMBER)—Offset 3h" on page 2007	00h
4h	1	"Primary Channel Cylinder Low register (P_CYL_LOW)—Offset 4h" on page 2008	00h
5h	1	"Primary Channel Cylinder High register (P_CYL_HIGH)—Offset 5h" on page 2008	00h
6h	1	"Primary Channel Device register (P_DRIVE_HEAD)—Offset 6h" on page 2009	00h
7h	1	"Primary Channel Status register (P_STATUS)—Offset 7h" on page 2009	00h

17.9.1 Primary Channel Error register (P_ERROR)—Offset 1h

Access Method

Type: I/O Register
(Size: 8 bits)

P_ERROR: [PCMDIDEBA] + 1h

PCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

PCMDIDEBA Reference: [B:0, D:19, F:0] + FCh

Default: 00h

7	4	0
0	0	0
P_ERROR_1		
Bit Range	Default & Access	Description
7:0	00h RW	Error (P_ERROR_1): Error.

17.9.2 Primary Channel Sector Count register (P_SECTOR_COUNT)—Offset 2h

Access Method

Type: I/O Register
(Size: 8 bits)

P_SECTOR_COUNT: [PCMDIDEBA] + 2h

PCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

PCMDIDEBA Reference: [B:0, D:19, F:0] + FCh

Default: 00h

Bit Range	Default & Access	Description
7:0	00h RW	Sector Count (P_SECTOR_COUNT_1): Sector Count.

17.9.3 Primary Channel Sector Number register (P_SECTOR_NUMBER)—Offset 3h

Access Method

Type: I/O Register
(Size: 8 bits)

P_SECTOR_NUMBER: [PCMDIDEBA] + 3h

PCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

PCMDIDEBA Reference: [B:0, D:19, F:0] + FCh

Default: 00h

Bit Range	Default & Access	Description
7:0	00h RW	Sector Number (P_SECTOR_NUMBER_1): Sector Number.

17.9.4 Primary Channel Cylinder Low register (P_CYL_LOW)—Offset 4h

Access Method

Type: I/O Register
(Size: 8 bits)

P_CYL_LOW: [PCMDIDEBA] + 4h

PCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

PCMDIDEBA Reference: [B:0, D:19, F:0] + FCh

Default: 00h

Bit Range	Default & Access	Description
7:0	00h RW	Cylinder Low (P_CYL_LOW_1): Cylinder Low.

17.9.5 Primary Channel Cylinder High register (P_CYL_HIGH)—Offset 5h

Access Method

Type: I/O Register
(Size: 8 bits)

P_CYL_HIGH: [PCMDIDEBA] + 5h

PCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

PCMDIDEBA Reference: [B:0, D:19, F:0] + FCh

Default: 00h

Bit Range	Default & Access	Description
7:0	00h RW	Cylinder High (P_CYL_HIGH_1): Cylinder High.

Bit Range	Default & Access	Description
6	0h RW	Device Ready (P_STATUS_DRDY): Device Ready.
5	0h RW	Device Fault/Stream Error (P_STATUS_DF): Device Fault/Stream Error.
4	0b RO	RSVD0: Reserved
3	0h RW	Data Request (P_STATUS_DRQ): Data Request.
2:1	0b RO	RSVD1: Reserved
0	0h RW	ERR/CHK (P_STATUS_ERR_CHK): ERR/CHK.

17.10 SATA Primary Write Control IO Registers

Table 198. Summary of SATA Primary Write Control I/O Registers—PCTLIDEBA

Offset	Size	Register ID—Description	Default Value
2h	1	"Primary Channel Device Control register (P_DEVICE_CTRL)—Offset 2h" on page 2011	00h

17.10.1 Primary Channel Device Control register (P_DEVICE_CTRL)—Offset 2h

Access Method

Type: I/O Register
(Size: 8 bits)

P_DEVICE_CTRL: [PCTLIDEBA] + 2h

PCTLIDEBA Type: PCI Configuration Register (Size: 32 bits)

PCTLIDEBA Reference: [B:0, D:19, F:0] + 104h

Default: 00h

7	4	0
0	0	0
RSVD0		RSVD1
P_DEVICE_CTRL_SRST		P_DEVICE_CTRL_nIEN

Bit Range	Default & Access	Description
7:3	0b RO	RSVD0: Reserved
2	0h RW	Soft Reset (P_DEVICE_CTRL_SRST): Soft Reset.
1	0h RW	Interrupt Enable, Negative Logic (P_DEVICE_CTRL_nIEN): Interrupt Enable, Negative Logic.
0	0b RO	RSVD1: Reserved

17.11 SATA Primary Read Control IO Registers

Table 199. Summary of SATA Primary Read Control I/O Registers—PCTLIDEBA

Offset	Size	Register ID—Description	Default Value
2h	1	"Primary Channel Alternate Status register (P_ALT_STATUS)—Offset 2h" on page 2012	00h

17.11.1 Primary Channel Alternate Status register (P_ALT_STATUS)—Offset 2h

Access Method

Type: I/O Register
(Size: 8 bits)

P_ALT_STATUS: [PCTLIDEBA] + 2h

PCTLIDEBA Type: PCI Configuration Register (Size: 32 bits)

PCTLIDEBA Reference: [B:0, D:19, F:0] + 104h

Default: 00h

7	0	0	0	4	0	0	0	0
P_ALT_STATUS_BSY	P_ALT_STATUS_DRDY	P_ALT_STATUS_DF	RSVD0	P_ALT_STATUS_DRQ	RSVD1	P_ALT_STATUS_ERR_CHK		

Bit Range	Default & Access	Description
7	0h RW	BUSY (P_ALT_STATUS_BSY): BUSY.
6	0h RW	Device Ready (P_ALT_STATUS_DRDY): Device Ready.
5	0h RW	Device Fault/Stream Error (P_ALT_STATUS_DF): Device Fault/Stream Error.
4	0b RO	RSVD0: Reserved
3	0h RW	Data Request (P_ALT_STATUS_DRQ): Data Request.
2:1	0b RO	RSVD1: Reserved
0	0h RW	ERR/CHK (P_ALT_STATUS_ERR_CHK): ERR/CHK.

17.12 SATA Primary Write Control IO Registers

Table 200. Summary of SATA Primary Write Control I/O Registers—PCTLIDEBA

Offset	Size	Register ID—Description	Default Value
2h	1	"Primary Channel Device Control register (P_DEVICE_CTRL)—Offset 2h" on page 2013	00h

17.12.1 Primary Channel Device Control register (P_DEVICE_CTRL)—Offset 2h

Access Method

Type: I/O Register
(Size: 8 bits)

P_DEVICE_CTRL: [PCTLIDEBA] + 2h

PCTLIDEBA Type: PCI Configuration Register (Size: 32 bits)

PCTLIDEBA Reference: [B:0, D:19, F:0] + 104h

Default: 00h

7	4	0
0	0	0
RSVD0		RSVD1
P_DEVICE_CTRL_SRST		P_DEVICE_CTRL_nIEN

Bit Range	Default & Access	Description
7:3	0b RO	RSVD0: Reserved
2	0h RW	Soft Reset (P_DEVICE_CTRL_SRST): Soft Reset.
1	0h RW	Interrupt Enable, Negative Logic (P_DEVICE_CTRL_nIEN): Interrupt Enable, Negative Logic.
0	0b RO	RSVD1: Reserved

17.13 SATA Secondary Read Command IO Registers

Table 201. Summary of SATA Secondary Read Command I/O Registers—SCMDIDEBA

Offset	Size	Register ID—Description	Default Value
1h	1	"Secondary Channel Error register (S_ERROR)—Offset 1h" on page 2014	00h
2h	1	"Secondary Channel Sector Count register (S_SECTOR_COUNT)—Offset 2h" on page 2015	00h
3h	1	"Secondary Channel Sector Number register (S_SECTOR_NUMBER)—Offset 3h" on page 2015	00h
4h	1	"Secondary Channel Cylinder Low register (S_CYL_LOW)—Offset 4h" on page 2016	00h
5h	1	"Secondary Channel Cylinder High register (S_CYL_HIGH)—Offset 5h" on page 2016	00h
6h	1	"Secondary Channel Device register (S_DRIVE_HEAD)—Offset 6h" on page 2017	00h
7h	1	"Secondary Channel Status register (S_STATUS)—Offset 7h" on page 2018	00h

17.13.1 Secondary Channel Error register (S_ERROR)—Offset 1h

Access Method

Type: I/O Register
(Size: 8 bits)

S_ERROR: [SCMDIDEBA] + 1h

SCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCMDIDEBA Reference: [B:0, D:19, F:0] + 100h

Default: 00h

7	4	0
0	0	0
S_ERROR_1		
Bit Range	Default & Access	Description
7:0	00h RW	Error (S_ERROR_1): Error.

17.13.2 Secondary Channel Sector Count register (S_SECTOR_COUNT)—Offset 2h

Access Method

Type: I/O Register
(Size: 8 bits)

S_SECTOR_COUNT: [SCMDIDEBA] + 2h

SCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCMDIDEBA Reference: [B:0, D:19, F:0] + 100h

Default: 00h

7				4					0
0	0	0	0	0	0	0	0	0	0
S_SECTOR_COUNT_1									

Bit Range	Default & Access	Description
7:0	00h RW	Sector Count (S_SECTOR_COUNT_1): Sector Count.

17.13.3 Secondary Channel Sector Number register (S_SECTOR_NUMBER)—Offset 3h

Access Method

Type: I/O Register
(Size: 8 bits)

S_SECTOR_NUMBER: [SCMDIDEBA] + 3h

SCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCMDIDEBA Reference: [B:0, D:19, F:0] + 100h

Default: 00h

7				4					0
0	0	0	0	0	0	0	0	0	0
S_SECTOR_NUMBER_1									

Bit Range	Default & Access	Description
7:0	00h RW	Sector Number (S_SECTOR_NUMBER_1): Sector Number.

17.13.4 Secondary Channel Cylinder Low register (S_CYL_LOW)—Offset 4h

Access Method

Type: I/O Register
(Size: 8 bits)

S_CYL_LOW: [SCMDIDEBA] + 4h

SCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCMDIDEBA Reference: [B:0, D:19, F:0] + 100h

Default: 00h

Bit Range	Default & Access	Description
7:0	00h RW	Cylinder Low (S_CYL_LOW_1): Cylinder Low.

17.13.5 Secondary Channel Cylinder High register (S_CYL_HIGH)—Offset 5h

Access Method

Type: I/O Register
(Size: 8 bits)

S_CYL_HIGH: [SCMDIDEBA] + 5h

SCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCMDIDEBA Reference: [B:0, D:19, F:0] + 100h

Default: 00h

Bit Range	Default & Access	Description
7:0	00h RW	Cylinder High (S_CYL_HIGH_1): Cylinder High.

17.13.6 Secondary Channel Device register (S_DRIVE_HEAD)—Offset 6h

Access Method

Type: I/O Register
(Size: 8 bits)

S_DRIVE_HEAD: [SCMDIDEBA] + 6h

SCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCMDIDEBA Reference: [B:0, D:19, F:0] + 100h

Default: 00h

7			4				0
0	0	0	0	0	0	0	0
RSVD0			S_DRIVE_HEAD_1	RSVD1			

Bit Range	Default & Access	Description
7:5	0b RO	RSVD0: Reserved
4	0h RW	Device (S_DRIVE_HEAD_1): Device.
3:0	0b RO	RSVD1: Reserved

17.13.7 Secondary Channel Status register (S_STATUS)—Offset 7h

Access Method

Type: I/O Register
(Size: 8 bits)

S_STATUS: [SCMDIDEBA] + 7h

SCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCMDIDEBA Reference: [B:0, D:19, F:0] + 100h

Default: 00h

7	0	0	0	4	0	0	0	0
S_STATUS_BSY	S_STATUS_DRDY	S_STATUS_DF	RSVD0	S_STATUS_DRQ	RSVD1	S_STATUS_ERR_CHK		

Bit Range	Default & Access	Description
7	0h RW	BUSY (S_STATUS_BSY): BUSY.
6	0h RW	Device Ready (S_STATUS_DRDY): Device Ready.
5	0h RW	Device Fault/Stream Error (S_STATUS_DF): Device Fault/Stream Error.
4	0b RO	RSVD0: Reserved
3	0h RW	Data Request (S_STATUS_DRQ): Data Request.
2:1	0b RO	RSVD1: Reserved
0	0h RW	ERR/CHK (S_STATUS_ERR_CHK): ERR/CHK.

17.14 SATA Secondary Write Command IO Registers

Table 202. Summary of SATA Secondary Write Command I/O Registers—SCMDIDEBA

Offset	Size	Register ID—Description	Default Value
1h	1	"Secondary Channel Features register (S_FEATURES)—Offset 1h" on page 2019	00h
7h	1	"Secondary Channel Command register (S_COMMAND)—Offset 7h" on page 2020	00h

17.14.1 Secondary Channel Features register (S_FEATURES)—Offset 1h

Access Method

Type: I/O Register
(Size: 8 bits)

S_FEATURES: [SCMDIDEBA] + 1h

SCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCMDIDEBA Reference: [B:0, D:19, F:0] + 100h

Default: 00h

7				4					0
0	0	0	0	0	0	0	0	0	0
S_FEATURES_1									

Bit Range	Default & Access	Description
7:0	00h RW	Features (S_FEATURES_1): Features.

17.14.2 Secondary Channel Command register (S_COMMAND)—Offset 7h

Access Method

Type: I/O Register
(Size: 8 bits)

S_COMMAND: [SCMDIDEBA] + 7h

SCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCMDIDEBA Reference: [B:0, D:19, F:0] + 100h

Default: 00h

7				4				0
0	0	0	0	0	0	0	0	0
S_COMMAND_1								
Bit Range	Default & Access	Description						
7:0	00h RW	Command (S_COMMAND_1): Command.						

17.15 SATA Secondary Read Control IO Registers

Table 203. Summary of SATA Secondary Read Control I/O Registers—SCTLIDEBA

Offset	Size	Register ID—Description	Default Value
2h	1	"Secondary Channel Alternate Status register (S_ALT_STATUS)—Offset 2h" on page 2021	00h

17.15.1 Secondary Channel Alternate Status register (S_ALT_STATUS)—Offset 2h

Access Method

Type: I/O Register
(Size: 8 bits)

S_ALT_STATUS: [SCTLIDEBA] + 2h

SCTLIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCTLIDEBA Reference: [B:0, D:19, F:0] + 108h

Default: 00h

7			4			0
0	0	0	0	0	0	0

0	0	0	0	0	0	0	0	0	0
S_FEATURES_1									

Bit Range	Default & Access	Description
7:0	00h RW	Features (S_FEATURES_1): Features.

17.16.2 Secondary Channel Command register (S_COMMAND)—Offset 7h

Access Method

Type: I/O Register
(Size: 8 bits)

S_COMMAND: [SCMDIDEBA] + 7h

SCMDIDEBA Type: PCI Configuration Register (Size: 32 bits)

SCMDIDEBA Reference: [B:0, D:19, F:0] + 100h

Default: 00h

7				4					0
0	0	0	0	0	0	0	0	0	0
S_COMMAND_1									
Bit Range	Default & Access	Description							
7:0	00h RW	Command (S_COMMAND_1): Command.							

17.17 SATA Lane 0 Electrical Register Address Map

Table 205. Summary of SATA Lane 0 Electrical Message Bus Registers—0xA3 (Global Offset 2200h)

Offset	Register ID—Description	Default Value
0h	"PCS_DWORD0 (pcs_dword0)—Offset 0h" on page 2026	00010080h
4h	"PCS_DWORD1 (pcs_dword1)—Offset 4h" on page 2028	00600060h
8h	"PCS_DWORD2 (pcs_dword2)—Offset 8h" on page 2029	00000000h
Ch	"PCS_DWORD3 (pcs_dword3)—Offset Ch" on page 2030	5515ACAAh
10h	"PCS_DWORD4 (pcs_dword4)—Offset 10h" on page 2031	575555C1h
14h	"PCS_DWORD5 (pcs_dword5)—Offset 14h" on page 2032	00003E63h
18h	"PCS_DWORD6 (pcs_dword6)—Offset 18h" on page 2033	FFFFFFFFh
1Ch	"PCS_DWORD7 (pcs_dword7)—Offset 1Ch" on page 2034	00000009h
20h	"PCS_DWORD8 (pcs_dword8)—Offset 20h" on page 2035	000000C4h
24h	"PCS_DWORD9 (pcs_dword9)—Offset 24h" on page 2036	00000000h
28h	"PCS_DWORD10 (pcs_dword10)—Offset 28h" on page 2038	00000000h
2Ch	"PCS_DWORD11 (pcs_dword11)—Offset 2Ch" on page 2039	0F000000h
30h	"PCS_DWORD12 (pcs_dword12)—Offset 30h" on page 2041	00250F00h
34h	"PCS_DWORD13 (pcs_dword13)—Offset 34h" on page 2042	00000000h
38h	"PCS_DWORD14 (pcs_dword14)—Offset 38h" on page 2042	007A0018h
3Ch	"PCS_DWORD15 (pcs_dword15)—Offset 3Ch" on page 2044	04100300h
40h	"PCS_DWORD16 (pcs_dword16)—Offset 40h" on page 2045	01000001h
44h	"PCS_DWORD17 (pcs_dword17)—Offset 44h" on page 2047	01000001h
48h	"PCS_DWORD18 (pcs_dword18)—Offset 48h" on page 2048	00008080h
4Ch	"PCS_DWORD19 (pcs_dword19)—Offset 4Ch" on page 2049	00004F10h
50h	"PCS_DWORD20 (pcs_dword20)—Offset 50h" on page 2050	80808080h
54h	"PCS_DWORD21 (pcs_dword21)—Offset 54h" on page 2051	80808080h
58h	"PCS_DWORD22 (pcs_dword22)—Offset 58h" on page 2052	00000000h
5Ch	"PCS_DWORD23 (pcs_dword23)—Offset 5Ch" on page 2053	00180888h
60h	"PCS_DWORD24 (pcs_dword24)—Offset 60h" on page 2053	0001C020h

Type: Message Bus Register
(Size: 32 bits)

Op Codes:

0h - Read, 1h - Write

Intel Atom® Processor E3800 Product Family
Datasheet
2026

Bit Range	Default & Access	Description
11	0h RW	reg_rcvdetect_pulse_width_ovrd: override enable for rcvdetect_pulse_width
10:8	0h RW	reg_rcvdetect_pulse_width_2_0: override value for rcvdetect_pulse_width
7	1h RW	reg_tx1_soft_reset_n: Active low reset to independently reset Tx lane1 in Display Port 0: Lane 1 reset 1: Lane 1 active
6	0h RW	reg_tx_8b10b_bypass: Bypass 8b10b encoder (for SAPIS etc interface.) 0 = Disable 8b/10b encoder bypass 1 = Enable 8b/10b encoder bypass
5	0h RW	reg_tx_laneup: Unused in Tx
4	0h RW	reg_left_txfifo_rst_master2: override enable = reg_lanedeskew_strap_ovrd
3	0h RW	reg_right_txfifo_rst_master2: override enable = reg_lanedeskew_strap_ovrd
2	0h RW	reg_plllinksynch_ovrden: Override enable for reg_pllinsync_ovrd 0 = Use default delay in hardware 1 = Use reg_plllinksynch_ovrd
1	0h RW	reg_plllinksynch_ovrd: override value for plllinksynch
0	0h RW	reg_tx1_cmmdisparity: Sets the initial disparity during Compliance Measurement Mode, used together with pcs_txcompliance pulse. 0 = set negative disparity 1 = set positive disparity

Bit Range	Default & Access	Description
5	1h RW	soft_reset_n : Active low soft reset override
4	0h RW	reg_diginelben : Override for near end digital loopback.
3	0h RW	reg_digifelben : Override for far end digital loopback
2	0h RW	reg_strapgroup_ovrden : Override Enable for Strap Group
1	0h RW	reg_yank_timer_done_b_ovrd : Override for yank_timer_done_b
0	0h RW	reg_yank_timer_done_b_ovrd_en : Override Enable for yank_timer_done_b

17.17.3 PCS_DWORD2 (pcs_dword2)—Offset 8h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword2: [Port: 0xA3] + (2200h + 8h)

Op Codes:

0h - Read, 1h - Write

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
reg_rxpwrfsm_pibiasoff_delay_3_0	cri_sqdbexittimer_override_3_0	cri_sqdbentrytimer_override_5_0	reg_rxdrcgtsqsel_1_0	cri_reut_SlaveSideDataCheckingEn	cri_sqdbtimer_ovren	cri_rxpwrfsm_timer_ovren	reg_rxdidle	cri_rxdrawdata_sel
				cri_dynkalign_eco3302703_mode	cri_dynkalign_eco3302703_ovren	reg_rxpwrfsm_pibiasoff_ovrride	cri_reset_kalignick	cri_ebptrrst
							cri_comdispfix	cri_forcebankhit
							cri_kalignmode_1_0	cri_skpprocdis
								cri_elasticbuffer_maskdis

Bit Range	Default & Access	Description
31:28	0h RW	reg_rxpwrfsm_pibiasoff_delay_3_0 : Override value for delay (in 2ns increments) between deassertion of opianclkbufen and opibiasen
27:24	0h RW	cri_sqdbexittimer_override_3_0 : Rx squelch exit debounce timer
23:18	0h RW	cri_sqdbentrytimer_override_5_0 : Rx squelch entry debounce timer
17:16	0h RW	reg_rxdrcgtsqsel_1_0 : Squelch output select

Bit Range	Default & Access	Description
15	0h RW	cri_reut_SlaveSideDataCheckingEn: Enable REUT slave side checking while in loopback slave
14	0h RW	cri_sqdbtimer_ovren: Squelch debounce timer override enable
13	0h RW	cri_rxpwrfsm_timer_ovren: Rx power management fsm timer override enable
12	0h RW	reg_rxidle: Chicken bit to override i_rxidle from controller and keep Rx in P0 or P0s
11	0h RW	cri_rxrawdata_sel: When asserted bypass K-align, 10b/8b decoder and Elastic buffer
10	0h RW	cri_dynkalign_eco3302703_mode: Kalign Mode Override Value When cri_dynkalign_eco3302703_ovren is set, this value selects kalignmode 0 - use register bits cri_kalignmode[1:0] to select kalignmode 1 - select the 4 COM kalign mode'
9	0h RW	cri_dynkalign_eco3302703_ovren: Kalign Mode Override Enable Overrides kalign mode select pin, allowing config bit kalignmode_override_val to select kalignmode.
8	0h RW	reg_rxpwrfsm_pibiasoff_override: When asserted selects reg_rxpwrfsm_pibiasoff_delay[3:0]
7	0h RW	cri_reset_kalignlck: When asserted resets Kalign lock indication and Kalign is performed again. The conditions when this would assert includes and is not restricted to any power management states (L0s, L1) or polling quiet states etc.
6	0h RW	cri_ebptrrst: Global broadcast to all lanes that the Elastic Buffer pointers should be reset. This is a pulse and will be generated when we need to reset the pointers because of collision or various other reasons.
5	0h RW	cri_comdispfix: Chicken bit to force disparity in dynamic K-align mode
4	0h RW	cri_forcebankhit: Chicken bit to enable data appear on NOA post k-align lock although k-align block is not achieving lock. This is only for NOA observeability and not for other purpose
3:2	0h RW	cri_kalignmode_1_0: KALIGN Mode Select 00 = dynamic kalign all the time. Accounts for bit slips on incoming stream which can cause symbol to be detected on different bank 10 = dynamic kalign up to L0 x1 = static kalign (same as GDG). Assumes symbol always detected on same data bank
1	0h RW	cri_skpprocdis: SKIP Ordered-Set Processing Disable When this configuration bit is asserted, then SKIP ordered=sets will be ignored (in EB block). Used in Elastic buffer block. 0 = Normal operation. SKIP ordered=sets will be processed by the Elastic Buffer 1 = SKIP processing disabled.
0	0h RW	cri_elasticbuffer_maskdis: Config bit (chicken bit) to disable the masking logic after elec idle ordered set is seen

17.17.4 PCS_DWORD3 (pcs_dword3)—Offset Ch

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword3: [Port: 0xA3] + (2200h + Ch)

Op Codes:
0h - Read, 1h - Write

Default: 5515ACAAh

17.17.5 PCS_DWORD4 (pcs_dword4)—Offset 10h

17.17.6 PCS_DWORD5 (pcs_dword5)—Offset 14h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs dword5: [Port: 0xA3] + (2200h + 14h)

Op Codes:

0h - Read, 1h - Write

Default: 00003E63h

31	28	24	20	16	12	8	4	0
0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 1 1	1 1 1 0	0 1 1 0	0 0 1 1
cri_dfx_patbufrain								
cri_dfx_prbspoly_2_0								
cri_dfx_patbufsize_1_0								
cri_dfx_patbufloop								
cri_dfx_patbufdwidth								
cri_dfx_patbufrainovr								
cri_dfx_marginmode								
cri_dfx_chk_sel								
cri_dfx_patchken								
cri_dfx_patgenen								
cri_dfx_clerrcnt								
cri_dfx_lcereset								
cri_dfx_lcestart								
cri_dfx_patbuf_7_0								
cri_dfx_patbuf_15_8								

Bit Range	Default & Access	Description
31	0h RW	cric_dfx_patbuftrain: Pattern Buffer Manual Training When DFXPATBUFTRAIN_OVR and DFXLCESTART are asserted, this manually controls whether the Pattern Buffers are in training or have completed training. 0 : Send training patterns (default) 1 : Send contents of DFXPATBUF
30:28	0h RW	cric_dfx_prbbspoly_2_0: PRBS Polynomial Select the polynomial to be used by the PRBS in the Pattern Generator and Pattern Checker. PRBS support 10b or 8b, which is indicated by the msb. 000 - $x^{16} + x^5 + x^4 + x^3 + 1$ (USB3/PCIe Scrambler) (8b) 001 - $x^{16} + x^{15} + x^{13} + x^4 + 1$ (SATA scrambler) (8b) 010 - $x^{31} + x^{28} + 1$ (8b) 011 - $x^7 + x^6 + 1$ (8b) 100 - $x^{15} + x^{14} + 1$ (10b) 101 - $x^{23} + x^{18} + 1$ (10b) 110 - $x^{31} + x^{28} + 1$ (10b) 111 - $x^7 + x^6 + 1$ (10b)
27:26	0h RW	cric_dfx_patbufsize_1_0: Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode)
25	0h RW	cric_dfx_patbufloop: Pattern Buffer Looping Enable Enables looping of the Pattern Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped
24	0h RW	cric_dfx_patbufdwidth: Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/retrieved. 0 : 10b (default) 1 : 8b
23	0h RW	cric_dfx_patbuftrainovr: Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Pattern Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training

Bit Range	Default & Access	Description
22	0h RW	cri_dfx_marginmode: Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled
21	0h RW	cri_dfx_chk_sel: Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-)8b decoding. 0: 10b domain 1: 8b domain
20	0h RW	cri_dfx_patchken: Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker
19	0h RW	cri_dfx_patgenen: Pattern Generator Enable This will activate the DFx bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator
18	0h RW	cri_dfx_clrerrcnt: Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset
17	0h RW	cri_dfx_lcereset: Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset
16	0h RW	cri_dfx_lcestart: Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFxLCESET is usually required. 0 : LCE stopped (default) 1 : LCE running
15:8	3Eh RW	cri_dfx_patbuf_7_0: Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). In 8b mode, the buffer is read as eight 10b chunks, where the 10th bit is unused and the 9th bit is the K-bit indicator. The first 10 bits should not equal the Comma Symbol: 'xx10111100'. DFxPATBUF[78] should not = '1'.
7:0	63h RW	cri_dfx_patbuf_15_8: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.

17.17.7 PCS_DWORD6 (pcs_dword6)—Offset 18h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword6: [Port: 0xA3] + (2200h + 18h)

Op Codes:

0h - Read, 1h - Write

Default: FFFFFFFFh

31	28	24	20	16	12	8	4	0
1	1	1	1	1	1	1	1	1
1	1	1	1	1	1	1	1	1
cri_dfx_prbseed_7_0	cri_dfx_prbseed_15_8	cri_dfx_prbseed_23_16	cri_dfx_prbseed_31_24					

Bit Range	Default & Access	Description
31:24	FFh RW	cri_dfx_prbseed_7_0: PRBS Seed Can be used for HVM determinism. The use of all zeroes can result in lockup.

Bit Range	Default & Access	Description
23:16	FFh RW	cri_dfx_prbsseed_15_8: PRBS Seed See cri_dfx_prbsseed[7:0] description.
15:8	FFh RW	cri_dfx_prbsseed_23_16: PRBS Seed See cri_dfx_prbsseed[7:0] description.
7:0	FFh RW	cri_dfx_prbsseed_31_24: PRBS Seed See cri_dfx_prbsseed[7:0] description.

17.17.8 PCS_DWORD7 (pcs_dword7)—Offset 1Ch

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword7: [Port: 0xA3] + (2200h + 1Ch)

Op Codes:

0h - Read, 1h - Write

Default: 00000009h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	1
0	0	0	0	0	0	0	0	0
dfx_cri_errcnt_7_0	dfx_cri_errcnt_15_8	i_rxcaldone	dfx_cri_lcemgnerr	cri_dfx_patgen2active	dfx_cri_patbufallfail	dfx_cri_patchkactive	dfx_cri_patgenactive	dfx_cri_lcetraindone
						dfx_cri_lcetrainactive	reserved501	cri_dfx_patgen2en
							cri_dfx_maxerrcnt_1_0	cri_dfx_prbstraincnt_3_0

Bit Range	Default & Access	Description
31:24	X RO	dfx_cri_errcnt_7_0: Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERESSET.
23:16	X RO	dfx_cri_errcnt_15_8: Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERESSET.
15	X RO	i_rxcaldone: RX Calibration Cycles Complete Indicator
14	X RO	dfx_cri_lcemgnerr: Local Compare Engine Margin Error Indicates that the error counter has reached its max value. This can be used by the Rx upartition during Margin Mode to determine when the eye width has closed.
13	X RO	cri_dfx_patgen2active: Pattern Generator 2 Active status indicator In a lane with two Tx paths, this indicates that the second Pattern Generator is in progress. The DFXPATGENACTIVE will only indicate that the first Pattern Generator is in progress.
12	X RO	dfx_cri_patbufallfail: Pattern Buffer All Fail status indicator Indicates that there has not been a single matching Pattern Buffer pattern. This could signify that an error occurred during training.
11	X RO	dfx_cri_patchkactive: Pattern Checker Active status indicator Indicates that the Pattern Checker is in progress (either Pattern Buffer or PRBS).
10	X RO	dfx_cri_patgenactive: Pattern Generator Active status indicator Indicates that the Pattern Generator is in progress (either Pattern Buffer or PRBS).

Bit Range	Default & Access	Description
9	X RO	dfx_cri_lcetraindone: Local Compare Engine Training Done status indicator Indicates that the Pattern Checker training is completed (either Pattern Buffer or PRBS). The Pattern Checker is now synchronized to the Pattern Generator.
8	X RO	dfx_cri_lcetrainactive: Local Compare Engine Training Active status indicator Indicates that the Pattern Checker training is in progress (either Pattern Buffer or PRBS).
7	0h RW	reserved501: reserved
6	0h RW	cri_dfx_patgen2en: Pattern Generator 2 Enable In a lane with two Tx paths, this enables the second Pattern Generator. The DFXPATGENEN will enable the first Pattern Generator. 0 : Disable second Pattern Generator (default) 1 : Enable second Pattern Generator
5:4	0h RW	cri_dfx_maxerrcnt_1_0: Maximum Error Count Selectable maximum value that the DFXERRCNT can reach before the Local Compare Engine is automatically stopped. 00 : 2 ¹⁶ (default) 01 : 2 ¹⁰ 10 : 2 ⁸ 11 : 2 ⁴
3:0	9h RW	cri_dfx_prbstraincnt_3_0: PRBS Training Count The number of consecutive cycles that the Pattern Checker's PRBS must be error free before it is considered synchronized. Default is 9.

17.17.9 PCS_DWORD8 (pcs_dword8)—Offset 20h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword8: [Port: 0xA3] + (2200h + 20h)

Op Codes:

0h - Read, 1h - Write

Default: 000000C4h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
reg_partial	reg_slumber	reg_tx2_cdr_override_2_0	reg_cdr_override_2_0	reg_ebuffmode	reg_usedclockchannel_1_0	reg_usedclockchannel_override	reg_gbl_override	reg_tx1_pclkon_inp2
								reg_tx2_pclkon_inp2
								reg_tx2_txenable
					cri_rxeb_ptr_init_3_0			
					reg_powerfsm_override	reg_suspend	reg_pclkcfginput	reg_useqclock
							cri_rxeb_hiwater_3_0	
								cri_rxeb_lowater_3_0

Bit Range	Default & Access	Description
31	0h RW	reg_partial: Override for i_partial
30	0h RW	reg_slumber: Override for i_slumber
29:27	0h RW	reg_tx2_cdr_override_2_0: Override for cdr_override strap for second tx2

Bit Range	Default & Access	Description
26:24	0h RW	reg_cdr_override_2_0: Override for cdr_override strap
23	0h RW	reg_ebuffmode: Override for ebuffmode (no functionality in p1271 phase1 design)
22:21	0h RW	reg_usedclockchannel_1_0: Selects the active clock channel
20	0h RW	reg_usedclockchannel_ovrride: When asserted selects reg_usedclockchannel[1:0]
19	0h RW	reg_gbl_ovrride: Global override select
18	0h RW	reg_tx1_pclkon_inp2: When asserted keeps PCLK running in P2 mode. For DP this is used for Lane1
17	0h RW	reg_tx2_pclkon_inp2: When asserted keeps PCLK running in P2 mode. This is reserved (no impact) for PCIe/DMI and used for DP Lane2
16	0h RW	reg_tx2_txenable: Override for i_txenable for tx2
15:12	0h RW	cri_rxeb_ptr_init_3_0: Config override for initial value of Rx elastic buffer read pointer
11	0h RW	reg_powerfsm_ovrride: When asserted overrides for Tx power fsm are selected
10	0h RW	reg_suspend: Override for suspend
9	0h RW	reg_pclkcfcinput: Override for pclkcfcinput strap
8	0h RW	reg_useqclock: Override for useqclock; MUX select for I or Q clk for TX clocking
7:4	Ch RW	cri_rxeb_hiwater_3_0: Elastic buffer high watermark based on which SKP is removed
3:0	4h RW	cri_rxeb_lowater_3_0: Elastic buffer low watermark based on which SKP is added

17.17.10 PCS_DWORD9 (pcs_dword9)—Offset 24h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword9: [Port: 0xA3] + (2200h + 24h)

Op Codes:

0h - Read, 1h - Write

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
reserved502	reg_strapgroup_4_0	reg_powerdown_1_0	reg_pcs_txcmnkeepdisable_ovrd	reg_straplane_5_0	reg_tx1_powerdown_override	reg_tx2_powerdown_override	reg_txdatavalid	reg_txdeemp_1_0

27	0h RW	reserved520: reserved
26	0h RW	i_rxsqfsm_timersel: Sqelch FSM Timer Select 0 - Selects 25Mhz values for sqelch timer and shunt pulse generation . 1 - Selects 100Mhz values for sqelch timer and shunt pulse generation. This register is applicable to synchronous sqelch startup mode.

Bit Range	Default & Access	Description
25	0h RW	i_rxsq_asyncmode_h : Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualify it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered.
24	1h RW	i_rxsquelchstby_h : Fast Squelch Enable Mode Bit to keep the IREF (ivrefen) on during P2 and reduce squelch startup time.

10:9	0h RW	lrc_rdy_target_1_0: LRC Ready Pulse Target Indicates which lrc target to recompute when lrc_rdy_ovd is strobed 00: irefrccode 01: txrccode 10: rxtermrccode 11: rxvgarccode
8	0h RW	lrc_rdy_ovd: LRC Ready Override Recomputes the selected local rcomp code and generates a pulse 1 cal_clk cycle wide on the lrc_rdy signal that is selected in bits [2:1]. User must clear this bit before generating another pulse. Note: User should disable PM and PER. FSM can take control and codes can be overridden.
7	0h RW	rxtermpmrcen: PM RCOMP Enable for Rx Termination 1 - Enables the RCOMP update to occur while RX is in power management state if periodic RCOMP is enabled. If this bit is set and the PHY is not in a power management state, no update will occur. 0 - Disables power management qualifier to the RCOMP update; therefore RCOMP updates will be based on the state of the target periodic bit.
6	0h RW	rxvgapmrcen: PM RCOMP Enable for Rx VGA (Same description as the RxTerm PM Rcomp Enable.)
5	0h RW	txpmpmrcen: PM RCOMP Enable for Tx 1 - Enables the RCOMP update to occur while TX is in power management state if periodic RCOMP is enabled. If this bit is set and the PHY is not in a power management state, no update will occur. 0 - Disables power management qualifier to the RCOMP update; therefore RCOMP updates will be based on the state of the target periodic bit.
4	0h RW	irefpmrcen: IREF PM RCOMP Enable 1 - Enables the RCOMP update to occur while TX/RX is in the P1 or P2 (partial or slumber) power management state if periodic RCOMP is enabled. If this bit is set and the PHY is not in a power management state, no update will occur. 0 - Disables power management qualifier to the RCOMP update; therefore RCOMP updates will be based on the state of the target periodic bit.
3	0h RW	rxtermperrcen: Periodic RCOMP Enable for Rx Termination 1 - Enables the periodic RCOMP update for specified block. 0 - Disables periodic RCOMP update for specified block.
2	0h RW	rxvgaperrcen: Periodic RCOMP Enable for Rx VGA 1 - Enables the periodic RCOMP update for specified block. 0 - Disables periodic RCOMP update for specified block.
1	0h RW	txperrcen: Periodic RCOMP Enable for Tx 1 - Enables the periodic RCOMP update for specified block. 0 - Disables periodic RCOMP update for specified block.
0	1h RW	irefperrcen: Periodic RCOMP Enable for Iref 1 - Enables the periodic RCOMP update for specified block. 0 - Disables periodic RCOMP update for specified block.

Bit Range	Default & Access	Description
11:8	0h RW	ovisa1_lanesel_3_0 : VISA Lane Select for Lane1. Selects the byte of data to be sent out on lane1.
7	0h RW	ovisa_bypass : VISA Bypass. Allows for signals to be passed asynchronously through VISA block. Applies to both lane0 and lane1. 0 : Flop signals in local VISA block (default) 1 : Bypass flops in local VISA block
6:4	0h RW	ovisa0_clkssel_2_0 : VISA Clock Select for Lane0. Selects the source synchronous clock to be used for data being sent on lane0.
3:0	0h RW	ovisa0_lanesel_3_0 : VISA Lane Select for Lane0. Selects data byte to be driven out of VISA-0 byte. Can be either clocked or unclocked data

17.18.16 TX_DWORD15 (tx_dword15)—Offset 3Ch

Access Method

Type: Message Bus Register
(Size: 32 bits)

tx_dword15: [Port: 0xA6] + (280h + 3Ch)

Op Codes:

0h - Read, 1h - Write

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
reserved551	reserved550	reserved549	reserved548	reserved547	reserved546	reserved545	reserved544	

Bit Range	Default & Access	Description
31:30	0h RO	reserved551 : reserved
29:24	0h RO	reserved550 : The slices used in R2 for DE (PstC=X,C=Y,PreC=Y)
23:22	0h RO	reserved549 : reserved
21:16	0h RO	reserved548 : The slices used in R2 for FS (PstC=X,C=Y,PreC=X)

17.19.1 PCS_DWORD0 (pcs_dword0)—Offset 0h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword0: [Port: 0xA3] + (2400h + 0h)

Op Codes:

0h - Read, 1h - Write

Default: 00010080h

October 2018
Document Number: 538136, Rev. 4.3

Access Method

pcs dword1: [Port: 0xA3] + (2400h + 4h)

Op Codes:

0h - Read, 1h - Write

Default: 00600060h

Bit Range	Default & Access	Description
31:24	0h RW	reg_tx fsm_4us_delay_7_0: Override counter value for 4 us delay in tx fsm lane reset to tx biasen delay
23	0h RW	reg_softreset_enable: When '1' the soft_reset_n bit will control the lane reset When '0' the hardware reset will control the lane reset Note for DP: In addition to soft_reset_n, which will reset both TX0 and TX 1 in the lane, the reg_tx1_soft_reset_n bit can be used to reset only TX1 in the lane and reg_tx2_soft_reset_n bit can be used to reset only TX2
22	1h RW	cri_rxeb_eiosenable: When 1 enables EIOS based Rx power down

Bit Range	Default & Access	Description
21	1h RW	cri_rxdigfiltsq_enable: When 1 enables unsquelch based Rx power up in P0 or P0s
20	0h RW	reg_txfsfm_delay_ovrd: Override enable bit for reg_txfsfm_4us_delay
19:16	0h RW	reg_txfsfm_4us_delay_11_8: Override counter value for 4 us delay in txfsfm lane reset to txbiasen delay
15:14	0h RW	reg_pclk_rate_1_0: Override for pclk_rate 00 = gen1 01 = gen2 10 = gen3 11 = GbE
13:12	0h RW	reg_rate_1_0: Override for i_rate 00 = gen1 01 = gen2 10 = gen3 11 = GbE
11:9	0h RW	reg_phymode_2_0: Override for PHY Mode Selection 000 = PCIE 001 = USB3 010 = GbE 011 = SATA/SAPIS 100 = Display 101 = DMI 110 = CIO 111 =Reserved
8	0h RW	reg_modeovren: When asserted selects register override bits for phymode, datawidth etc
7:6	1h RW	reg_datawidth: Override for Tx data interface width. 00 - Unused 01 - x8/x10 width (default) 10 - x16/x20 width 11 - x32/x40 width
5	1h RW	soft_reset_n: Active low soft reset override
4	0h RW	reg_diginelben: Override for near end digital loopback.
3	0h RW	reg_digifelben: Override for far end digital loopback
2	0h RW	reg_strapgroup_ovrden: Override Enable for Strap Group
1	0h RW	reg_yank_timer_done_b_ovrd: Override for yank_timer_done_b
0	0h RW	reg_yank_timer_done_b_ovrd_en: Override Enable for yank_timer_done_b

17.19.3 PCS_DWORD2 (pcs_dword2)—Offset 8h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword2: [Port: 0xA3] + (2400h + 8h)

Op Codes:

0h - Read, 1h - Write

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
reg_rxpwrfsm_pibiasoff_delay_3_0	cri_sqdbexittimer_override_3_0	cri_sqdbentrytimer_override_5_0	reg_rxdrcgtsqsel_1_0	cri_reut_SlaveSideDataCheckingEn	cri_sqdbtimer_ovren	cri_rxpwrfsm_timer_ovren	reg_rxidle	cri_rxrawdata_sel
				cri_dynkalign_eco3302703_mode	cri_dynkalign_eco3302703_ovren	reg_rxpwrfsm_pibiasoff_ovrride	cri_reset_kalignlck	cri_ebptrrst
							cri_comdispfix	cri_forcebankhit
							cri_kalignmode_1_0	cri_skpprocdis
								cri_elasticbuffer_maskdis

Bit Range	Default & Access	Description
31:28	0h RW	reg_rxpwrfsm_pibiasoff_delay_3_0: Override value for delay (in 2ns increments) between deassertion of opianclkbufen and opibiasen
27:24	0h RW	cri_sqdbexittimer_override_3_0: Rx squelch exit debounce timer
23:18	0h RW	cri_sqdbentrytimer_override_5_0: Rx squelch entry debounce timer
17:16	0h RW	reg_rxdrcgtsqsel_1_0: Squelch output select
15	0h RW	cri_reut_SlaveSideDataCheckingEn: Enable REUT slave side checking while in loopback slave
14	0h RW	cri_sqdbtimer_ovren: Squelch debounce timer override enable
13	0h RW	cri_rxpwrfsm_timer_ovren: Rx power management fsm timer override enable
12	0h RW	reg_rxidle: Chicken bit to override i_rxidle from controller and keep Rx in P0 or P0s
11	0h RW	cri_rxrawdata_sel: When asserted bypass K-align, 10b/8b decoder and Elastic buffer
10	0h RW	cri_dynkalign_eco3302703_mode: Kalign Mode Override Value When cri_dynkalign_eco3302703_ovren is set, this value selects kalignmode 0 - use register bits cri_kalignmode[1:0] to select kalignmode 1 - select the 4 COM kalign mode'
9	0h RW	cri_dynkalign_eco3302703_ovren: Kalign Mode Override Enable Overrides kalign mode select pin, allowing config bit kalignmode_override_val to select kalignmode.
8	0h RW	reg_rxpwrfsm_pibiasoff_ovrride: When asserted selects reg_rxpwrfsm_pibiasoff_delay[3:0]
7	0h RW	cri_reset_kalignlck: When asserted resets Kalign lock indication and Kalign is performed again. The conditions when this would assert includes and is not restricted to any power management states (L0s, L1) or polling quiet states etc.
6	0h RW	cri_ebptrrst: Global broadcast to all lanes that the Elastic Buffer pointers should be reset. This is a pulse and will be generated when we need to reset the pointers because of collision or various other reasons.
5	0h RW	cri_comdispfix: Chicken bit to force disparity in dynamic K-align mode

Bit Range	Default & Access	Description
4	0h RW	cri_forcebankhit: Chicken bit to enable data appear on NOA post k-align lock although k-align block is not achieving lock. This is only for NOA observeability and not for other purpose
3:2	0h RW	cri_kalignmode_1_0: KALIGN Mode Select 00 = dynamic kalign all the time. Accounts for bit slips on incoming stream which can cause symbol to be detected on different bank 10 = dynamic kalign up to L0 x1 = static kalign (same as GDG). Assumes symbol always detected on same data bank
1	0h RW	cri_skpprocdis: SKIP Ordered-Set Processing Disable When this configuration bit is asserted, then SKIP ordered=sets will be ignored (in EB block). Used in Elastic buffer block. 0 = Normal operation. SKIP ordered=sets will be processed by the Elastic Buffer 1 = SKIP processing disabled.
0	0h RW	cri_elasticbuffer_maskdis: Config bit (chicken bit) to disable the masking logic after elec idle ordered set is seen

17.19.4 PCS_DWORD3 (pcs_dword3)—Offset Ch

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword3: [Port: 0xA3] + (2400h + Ch)

Op Codes:

0h - Read, 1h - Write

Default: 5515ACAAh

31	28	24	20	16	12	8	4	0
0	1	0	1	0	1	0	1	0
0	1	0	1	0	0	0	1	0

cri_dfx_patbuf_55_48	cri_dfx_patbuf_63_56	cri_dfx_patbuf_71_64	cri_dfx_patbuf_79_72					

Bit Range	Default & Access	Description
31:24	55h RW	cri_dfx_patbuf_55_48: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.
23:16	15h RW	cri_dfx_patbuf_63_56: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.
15:8	ACH RW	cri_dfx_patbuf_71_64: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.
7:0	AAh RW	cri_dfx_patbuf_79_72: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.

17.19.5 PCS_DWORD4 (pcs_dword4)—Offset 10h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword4: [Port: 0xA3] + (2400h + 10h)

Op Codes:

0h - Read, 1h - Write

Default: 575555C1h

31	28	24	20	16	12	8	4	0
0	1	0	1	0	1	1	0	1
								1
cri_dfx_patbuf_23_16								cri_dfx_patbuf_47_40

Bit Range	Default & Access	Description
31:24	57h RW	cri_dfx_patbuf_23_16: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.
23:16	55h RW	cri_dfx_patbuf_31_24: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.
15:8	55h RW	cri_dfx_patbuf_39_32: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.
7:0	C1h RW	cri_dfx_patbuf_47_40: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.

17.19.6 PCS_DWORD5 (pcs_dword5)—Offset 14h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword5: [Port: 0xA3] + (2400h + 14h)

Op Codes:

0h - Read, 1h - Write

Default: 00003E63h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	1	1	1
								0
cri_dfx_patbuf_7_0								cri_dfx_patbuf_15_8

Bit Range	Default & Access	Description
31	0h RW	cri_dfx_patbuftrain: Pattern Buffer Manual Training When DFXPATBUFTRAINOVR and DFXLCESTART are asserted, this manually controls whether the Pattern Buffers are in training or have completed training. 0 : Send training patterns (default) 1 : Send contents of DFXPATBUF
30:28	0h RW	cri_dfx_prbspoly_2_0: PRBS Polynomial Select the polynomial to be used by the PRBS in the Pattern Generator and Pattern Checker. PRBS support 10b or 8b, which is indicated by the msb. 000 - $x^{16} + x^5 + x^4 + x^3 + 1$ (USB3/PCIe Scrambler) (8b) 001 - $x^{16} + x^{15} + x^{13} + x^4 + 1$ (SATA scrambler) (8b) 010 - $x^{31} + x^{28} + 1$ (8b) 011 - $x^7 + x^6 + 1$ (8b) 100 - $x^{15} + x^{14} + 1$ (10b) 101 - $x^{23} + x^{18} + 1$ (10b) 110 - $x^{31} + x^{28} + 1$ (10b) 111 - $x^7 + x^6 + 1$ (10b)
27:26	0h RW	cri_dfx_patbufsize_1_0: Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode)
25	0h RW	cri_dfx_patbufloop: Pattern Buffer Looping Enable Enables looping of the Pattern Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped
24	0h RW	cri_dfx_patbufdwidth: Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/retrieved. 0 : 10b (default) 1 : 8b
23	0h RW	cri_dfx_patbuftrainovr: Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Pattern Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training
22	0h RW	cri_dfx_marginmode: Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled
21	0h RW	cri_dfx_chk_sel: Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-)8b decoding. 0: 10b domain 1: 8b domain
20	0h RW	cri_dfx_patchken: Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker
19	0h RW	cri_dfx_patgenen: Pattern Generator Enable This will activate the DFX bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator
18	0h RW	cri_dfx_clrerrcnt: Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset
17	0h RW	cri_dfx_lcereset: Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset
16	0h RW	cri_dfx_lcestart: Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFXLCERESET is usually required. 0 : LCE stopped (default) 1 : LCE running
15:8	3Eh RW	cri_dfx_patbuf_7_0: Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). In 8b mode, the buffer is read as eight 10b chunks, where the 10th bit is unused and the 9th bit is the K-bit indicator. The first 10 bits should not equal the Comma Symbol: 'xx10111100'. DFXPATBUF[78] should not = '1'.
7:0	63h RW	cri_dfx_patbuf_15_8: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.

17.19.7 PCS_DWORD6 (pcs_dword6)—Offset 18h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword6: [Port: 0xA3] + (2400h + 18h)

Op Codes:

0h - Read, 1h - Write

Default: FFFFFFFFh

31	28	24	20	16	12	8	4	0
1	1	1	1	1	1	1	1	1
cri_dfx_prbseed_7_0								cri_dfx_prbseed_31_24

Bit Range	Default & Access	Description
31:24	FFh RW	cri_dfx_prbseed_7_0: PRBS Seed Can be used for HVM determinism. The use of all zeroes can result in lockup.
23:16	FFh RW	cri_dfx_prbseed_15_8: PRBS Seed See cri_dfx_prbseed[7:0] description.
15:8	FFh RW	cri_dfx_prbseed_23_16: PRBS Seed See cri_dfx_prbseed[7:0] description.
7:0	FFh RW	cri_dfx_prbseed_31_24: PRBS Seed See cri_dfx_prbseed[7:0] description.

17.19.8 PCS_DWORD7 (pcs_dword7)—Offset 1Ch

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword7: [Port: 0xA3] + (2400h + 1Ch)

Op Codes:

0h - Read, 1h - Write

Default: 00000009h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	1
dfx_cri_errcnt_7_0								cri_dfx_prbstraincnt_3_0

Bit Range	Default & Access	Description
31:24	X RO	dfx_cri_errcnt_7_0: Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERESSET.
23:16	X RO	dfx_cri_errcnt_15_8: Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERESSET.
15	X RO	i_rxcaldone: RX Calibration Cycles Complete Indicator
14	X RO	dfx_cri_lcemgnerr: Local Compare Engine Margin Error Indicates that the error counter has reached its max value. This can be used by the Rx upartition during Margin Mode to determine when the eye width has closed.
13	X RO	cri_dfx_patgen2active: Pattern Generator 2 Active status indicator In a lane with two Tx paths, this indicates that the second Pattern Generator is in progress. The DFXPATGENACTIVE will only indicate that the first Pattern Generator is in progress.
12	X RO	dfx_cri_patbufallfail: Pattern Buffer All Fail status indicator Indicates that there has not been a single matching Pattern Buffer pattern. This could signify that an error occurred during training.
11	X RO	dfx_cri_patchkactive: Pattern Checker Active status indicator Indicates that the Pattern Checker is in progress (either Pattern Buffer or PRBS).
10	X RO	dfx_cri_patgenactive: Pattern Generator Active status indicator Indicates that the Pattern Generator is in progress (either Pattern Buffer or PRBS).
9	X RO	dfx_cri_lcetraindone: Local Compare Engine Training Done status indicator Indicates that the Pattern Checker training is completed (either Pattern Buffer or PRBS). The Pattern Checker is now synchronized to the Pattern Generator.
8	X RO	dfx_cri_lcetrainactive: Local Compare Engine Training Active status indicator Indicates that the Pattern Checker training is in progress (either Pattern Buffer or PRBS).
7	0h RW	reserved501: reserved
6	0h RW	cri_dfx_patgen2en: Pattern Generator 2 Enable In a lane with two Tx paths, this enables the second Pattern Generator. The DFXPATGENEN will enable the first Pattern Generator. 0 : Disable second Pattern Generator (default) 1 : Enable second Pattern Generator
5:4	0h RW	cri_dfx_maxerrcnt_1_0: Maximum Error Count Selectable maximum value that the DFXERRCNT can reach before the Local Compare Engine is automatically stopped. 00 : 2^16 (default) 01 : 2^10 10 : 2^8 11 : 2^4
3:0	9h RW	cri_dfx_prbstraincnt_3_0: PRBS Training Count The number of consecutive cycles that the Pattern Checker's PRBS must be error free before it is considered synchronized. Default is 9.

17.19.9 PCS_DWORD8 (pcs_dword8)—Offset 20h

Access Method

Type: Message Bus Register
(Size: 32 bits)

pcs_dword8: [Port: 0xA3] + (2400h + 20h)

Op Codes:

0h - Read, 1h - Write

Default: 000000C4h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	1	1
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0

Bit Range	Default & Access	Description
31	0h RW	squelch_shunt_ovrd_en: Squelch Shunt Pulse Duration Override Enable Overrides the hardware default shunt pulse duration value 1: Shunt Pulse Duration Override Enable 0: Shunt Pulse Duration Override Disable
30:28	0h RW	squelch_shunt_cnt_2_0: Squelch Shunt Pulse Duration Override Value 000 = No shunt pulse generated 001 = 1 susclk cycles ... 111 = 7 susclk cycles
27	0h RW	reserved520: reserved
26	0h RW	i_rxsqasm_timersel: Squelch FSM Timer Select 0 - Selects 25Mhz values for squelch timer and shunt pulse generation . 1 - Selects 100Mhz values for squelch timer and shunt pulse generation. This register is applicable to synchronous squelch startup mode.
25	0h RW	i_rxsq_asyncmode_h: Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualify it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered.
24	1h RW	i_rxsquelchstby_h: Fast Squelch Enable Mode Bit to keep the IREF (ivrefen) on during P2 and reduce squelch startup time.

cri_susclkdisable_delay_4_0									
cri_data_dynclkgate_mode_1_0									
cri_eios_waittime_ovren									
cri_eios_waittime_6_0									

Bit Range	Default & Access	Description
31:24	0h RW	reserved528: reserved
23:17	0h RW	reserved527: reserved

Bit Range	Default & Access	Description
16	1h RW	cri_lanereset_clkgatectl: 1: The assertion of lane reset will have the effect of gating the susclk and de-asserting the internal laneclkreq. This mode is only valid when the data lane dynamic clock gating mode is set to a non-zero value (i.e. 01, 10, and 11). 0: The assertion of lane reset will have no effect on the gating of susclk and state of the internal laneclkreq signal.
15	1h RW	cri_lanereqforce: Controls whether the internal laneclkreq will be forced to 1 or 0 when cfg_data_dynclkgate_mode is set to 00 or 10. 1: force laneclkreq high 0: force laneclkreq low. This mode will likely be used when one of the lanes is disabled while other lanes in the family are enabled. In this case the internal laneclkreq of the disabled lane should be de-asserted (not influencing the clk gating decision)
14:10	10h RW	cri_susclkdisable_delay_4_0: This register will control the number of cycles to delay the susclk enable de-assertion, in addition to the de-assertion of the laneclkreq signal sent out of the datalane. The susclk enable must be continuously de-asserted for the duration of this delay in order for the de-asserted state to be captured by the clock gating controller. 5'b00000 - 0 Cycle Delay 5'b00001 - 1 Cycle Delay 5'b00010 - 2 Cycle Delay 5'b11110 - 30 Cycle Delay 5'b11111 - 31 Cycle Delay
9:8	0h RW	cri_data_dynclkgate_mode_1_0: Controls the dynamic clock gating behavior in the data lane. 00 - susclk gating and laneclkreq disabled (Forced to configured value). In this mode the susclk will not be gated under any circumstances and the laneclkreq sent out of the lane will be forced to a programmed value (can be forced high or low) 01 - susclk gating disabled, laneclkreq enabled . In this mode the susclk will not be gated under any circumstances. The laneclkreq sent out of the data lane will toggle based on whether the lane power state, susclk need and the previous lane's laneclkreq signal. 10 - susclk gating enabled, laneclkreq disabled (forced to configured value) - In this mode the susclk will be gated during P2/Slumber when there are no requests to change the TX common mode. The laneclkreq sent out of the lane will be forced to a programmed value (can be forced high or low) 11 - susclk gating and laneclkreq enabled - In this mode the susclk will be gated during P2/Slumber when there are no requests to change the TX common mode. The laneclkreq sent out of the data lane will toggle based on the lane power state, susclk need and the previous lane's laneclkreq signal.

18 USB Host Controller Interfaces (xHCI, EHCI)

The USB Host Controllers (xHCI, EHCI) supports:

- One (1) Super Speed (SS) port on xHCI
- Four (4) Low Speed (LS)/Full Speed (FS)/High Speed (HS) ports on xHCI or EHCI
- Two (2) High Speed (HS) High Speed Inter-Chip (HSIC) ports on xHCI

Note: The SS port must share a LS/FS/HS port to have a full SS connector leaving three LS/FS/HS ports available.

Note: Only one host controller (either xHCI or EHCI) can be used. To enable HSIC and SS ports, xHCI must be used.

18.1 Signal Descriptions

See [Chapter 2, "Physical Interfaces"](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal's function

Table 209. USB 3 SS Signals

Signal Name	Direction Plat. Power	Description
USB3_TXP/N[0]	O V1P0A	Data Out: High speed serialized data outputs. Used for debug mode in xHCI operation.
USB3_RXP/N[0]	I V1P0A	Data In: High speed serialized data inputs. Used for debug mode in xHCI operation.
USB3_REXT[0]	I	Resistor Compensation: An external resistor must be connected between this pin and package ground. Contact your Intel representative for details.

Table 210. USB 2 FS/HS Signals

Signal Name	Direction Plat. Power	Description
USB_DP/N[0:3]	I/O VUSB2	USB Data: High speed serialized data I/O. Note: USB_DP/N[1] used for debug mode in EHCI operation only. SS port must be implemented to have debug mode during xHCI operation.
USB_OC[0:1]#	I V1P8A	Over-Current Protection: Over-current notification for all USB ports (SS/FS/HS/LS).
USB_RCOMPI	I	Resistor Compensation: An external resistor must be connected. Contact your Intel representative for details.
USB_RCOMPO	O	Resistor Compensation: An external resistor must be connected. Contact your Intel representative for details.

Table 211. USB 2 HSIC Signals

Signal Name	Direction Plat. Power	Description
USB_HSIC[0:1]_DATA	I/O V1P24A	HSIC Data: High speed serialized data.
USB_HSIC[0:1]_STROBE	I/O V1P24A	HSIC Strobe: Strobe reference for data.
USB_HSIC_RCOMP	I	Resistor Compensation: An external resistor must be connected. Contact your Intel representative for details.

Figure 103.xHCI and EHCI Port Mapping

Note: xHCI (3.0) SS is the debug port for xHCI controller.

Note: EHCI (1/2.0) Port 1 is the debug port of the EHCI controller

18.2 USB 3.0 xHCI (Extensible Host Controller Interface)

The xHCI compliant host controller can control up to 7 USB host ports. It supports devices conforming to USB 1.x to 3.0 at bit rates up to 5 Gbps.

18.2.1 Features of USB 3.0 Host

The USB 3.0 Super Speed data interface is a four wire differential (TX and RX pairs) interface that supports simultaneous bi-directional data transmission. The interface supports a bit rate of 5 Gbps with a maximum theoretical data throughput over 3.2 Gbps due to 8b/10b symbol encoding scheme and protocol overhead (link flow control, packet framing and protocol overhead).

Low Frequency Periodic signaling (LFPS) is used to communicate initialization, training and power management information across a link that is in low power link state without using Super Speed signaling. This reduces power consumption.

The USB3.0 port may be paired with any USB2 port at the connector – selection of any USB2 port other than port 0 will require the appropriate mapping. [Figure 103](#) shows the USB3 port paired with USB2 port 0.

USB3.0 Controller Features

- Supported by xHCI software host controller interface
- USB3 port disable
- Supports local dynamic clock gating and trunk clock gating
- Supports USB 3.0 LPM (U0, U1, U2, and U3) and also a SS Disabled low power state

- Support for USB3 Debug Device

Note: Recommended not to disconnect the connection when a debug session is in progress.

18.2.2 Features of USB HSIC

HSIC is a 2-signal (strobe and data) source synchronous serial interface for on board inter-chip USB communication. The interface uses 240 MHz DDR signaling to provide High-Speed 480 Mb/s USB transfers which are 100% host driver compatible with traditional USB cable connected topologies. Full Speed (FS) and Low Speed (LS) USB transfers are not directly supported by the HSIC interface.

For details of HSIC applications supported, Contact local Intel Sales office.

Major feature and performance highlights are as follows:

- Supported by xHCI software host controller interface
- High-Speed 480 Mb/s data rate only
- Source-synchronous serial interface
- Interface Power is only consumed when a transfer is in progress
- No hot plug removal/attach at HSIC pins
- Signals driven at 1.2V standard LVCMOS levels
- Designed for low power applications
- Support for two host ports compliant to High Speed Inter-Chip Supplement (HSIC) to the USB 2.0 Specification. (USB 2.0)

18.3 USB 2.0 Enhanced Host Controller Interface (EHCI)

The EHCI compliant host controller supports up to 4 USB 2.0 ports in legacy mode. USB 2.0 allows data transfers up to 480 Mbps. The controller integrates a Root Matching Hub (RMH) to support USB 1.1 devices.

Note: The EHCI is not used when the xHCI is used. The EHCI is primarily present for legacy usage, in cases when xHCI support is not available.

Note: Intel recommends using the xHCI controller for the USB2.0 ports irrespective of whether USB3.0 ports are implemented. The EHCI controller is provided for legacy OS/driver compatibility which is generally not required for tablet platforms. Using the xHCI controller will deliver significant power and performance benefits.

When following this recommendation on a platform with no USB3.0 support, the Windows logo requirement of USB debug port may not be met. Please consult with Intel regarding the impact of this.

Note: Unlike the xHCI, bandwidth of all four ports on the EHCI is shared across a single HS (480 Mbps) internal link.

18.3.1 Features of EHCI USB 2.0 Controller

The EHCI USB2.0 Controller supports the following features:

- Compliant with the specification for: USB 1.x, 2.0 (1.5 Mbps, 12 Mbps, 480 Mbps).
- 4 Ports shared with xHCI controller
- Enhanced EHCI descriptor caching
- All ports provided through USB Rate Matching Hubs (RMH) to support FS/LS devices
- Supports one Debug port at USB2 transfer rates
- Supports of USB suspend mode including PLL turn off in S0.
- Supports wakeup from suspend states S5 and remote-suspend wakeup
- All USB2 ports provide support for HS/FS/LS devices
- Per port USB disable
- Supports local dynamic clock gating and trunk clock gating
- Supports USB 2.0 LPM (L0, L1 and L2 low power states)

14	0b RW/1C	Signaled System Error (SSE): This bit is set by the Intel PCH whenever it signals SERR# (internally). The SERR_EN bit (bit 8 in the Command Register) must be 1 for this bit to be set. See error handling section for complete list of conditions handled. Software clears this bit by writing a 1 to this bit location. Power Well: Core
13	0b RW/1C	Received Master-Abort Status (RMA): This bit is set when XHC, as a master, receives a master-abort status on a memory access. This is treated as a Host Error and halts the DMA engines. Software clears this bit by writing a 1 to this bit location. Power Well: Core
12	0b RW/1C	Received Target Abort Status (RTA): This bit is set when XHC, as a master, receives a target abort status on a memory access. This is treated as a Host Error and halts the DMA engines. Software clears this bit by writing a 1 to this bit location. Power Well: Core
11	0b RW/1C	Signaled Target-Abort Status (STA): This bit is used to indicate when the XHC function responds to a cycle with a target abort. Power Well: Core
10:9	01b RO	DEVSEL# Timing Status (DEVT): This 2-bit field defines the timing for DEVSEL# assertion. Read-Only. Power Well: Core
8	0b RW/1C	Master Data Parity Error Detected (MDPED): This bit is set by the Intel PCH whenever a data parity error is detected on a XHC read completion packet on the internal interface to the XHC host controller and bit 6 of the Command register is set to 1. Software clears this bit by writing a 1 to this bit location. Power Well: Core
7	1b RO	Fast Back-to-Back Capable (FBBC): Reserved as 1 Read-Only. Power Well: Core
6	0b RO	User Definable Features (UDF): Reserved as 0. Read-Only. Power Well: Core
5	0b RO	66 MHz Capable (MC): Reserved as 0. Read-Only. Power Well: Core
4	1b RO	Capabilities List (CL): Hardwired to 1 indicating that offset 34h contains a valid capabilities pointer. Power Well: Core
3	0b RO/V	Interrupt Status (IS): This read-only bit reflects the state of this function's interrupt at the input of the enable/disable logic. This bit is a 1 when the interrupt is asserted. This bit will be 0 when the interrupt is deasserted. The value reported in this bit is independent of the value in the Interrupt Enable bit. Power Well: Core
2:0	000b RO	Reserved (RSVD): Reserved. Power Well: Core

18.6.5 Revision ID (RID)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + 8h

Default: 00h

7				4					0
0	0	0	0	0	0	0	0	0	0
RID									

Bit Range	Default & Access	Field Name (ID): Description
7:0	00h RO/V	Revision ID (RID): See Chap 6 for value. Power Well: Core

18.6.6 Programming Interface (PI)—Offset 9h

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + 9h

Default: 30h

7				4					0
0	0	1	1	1	0	0	0	0	0
PI									

Bit Range	Default & Access	Field Name (ID): Description
7:0	30h RO	Programming Interface (PI): A value of 30h indicates that this USB Host Controller conforms to the XHCI specification. Power Well: Core

18.6.7 Sub Class Code (SCC)—Offset Ah

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + Ah

Default: 03h

7				4					0
0	0	0	0	0	0	0	1	1	1
SCC									

Bit Range	Default & Access	Field Name (ID): Description
7:0	03h RO	Sub Class Code (SCC): A value of 03h indicates that this is a Universal Serial Bus Host Controller. Power Well: Core

18.6.8 Base Class Code (BCC)—Offset Bh

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + Bh

Default: 0Ch

7			4				0
0	0	0	0	1	1	0	0
BCC							

Bit Range	Default & Access	Field Name (ID): Description
7:0	0Ch RO	Base Class Code (BCC): A value of 0Ch indicates that this is a Serial Bus controller. Power Well: Core

18.6.9 Master Latency Timer (MLT)—Offset Dh

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + Dh

Default: 00h

7			4				0
0	0	0	0	0	0	0	0
MLT							

Bit Range	Default & Access	Field Name (ID): Description
7:0	00h RO	Master Latency Timer (MLT): Because the XHC controller is internally implemented with arbitration on an internal interface, it does not need a master latency timer. The bits will be fixed at 0. Power Well: Core

18.6.10 Header Type (HT)—Offset Eh

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + Eh

Default: 00h

7	4	0
0	0	0
MFB	CL	

Bit Range	Default & Access	Field Name (ID): Description
7	0b RO	Multi-Function Bit (MFB): Read only indicating single function device. Power Well: Core
6:0	00h RO	Configuration layout (CL): Hardwired to 0 to indicate a standard PCI configuration layout. Power Well: Core

18.6.11 Memory Base Address (MBAR)—Offset 10h

Value in this register will be different after the enumeration process.

Access Method

Type: PCI Configuration Register
(Size: 64 bits)

Offset: [B:0, D:20, F:0] + 10h

Default: 0000000000000004h

6	6	5	5	4	4	4	3	3	2	2	2	1	1	8	4	0
3	0	6	2	8	4	0	6	2	8	4	0	6	2			
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
BA												RSVD			Prefetchable	Type
																RTE

Bit Range	Default & Access	Field Name (ID): Description
63:16	00000000 000h RW	Base Address (BA): Bits (63:16) correspond to memory address signals (63:16), respectively. This gives 64 KB of relocatable memory space aligned to 64 KB boundaries. Power Well: Core
15:4	000h RO	Reserved (RSVD): Reserved. Read-Only 0, this indicates that this function is requesting an 64KB block of memory. Power Well: Core
3	0b RO	Prefetchable: This bit is hardwired to 0 indicating that this range should not be prefetched. Power Well: Core
2:1	10b RO	Type: If this field is hardwired to 00 it indicates that this range can be mapped anywhere within 32-bit address space. If this field is hardwired to 10 it indicates that this range can be mapped anywhere within 64-bit address space. Power Well: Core

18.6.14 Capabilities Pointer (CAP_PTR)—Offset 34h

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + 34h

Default: 70h

7				4					0
0		1		1		0		0	0
					CAP_PTR				

Bit Range	Default & Access	Field Name (ID): Description
7:0	70h RO	Capabilities Pointer (CAP_PTR): This register points to the starting offset of the capabilities ranges. Power Well: Core

18.6.15 Interrupt Line (ILINE)—Offset 3Ch

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + 3Ch

Default: 00h

7				4					0
0		0		0		0		0	0
					ILINE				

Bit Range	Default & Access	Field Name (ID): Description
7:0	00h RW	Interrupt Line (ILINE): This data is not used by the Intel PCH. It is used as a scratchpad register to communicate to software the interrupt line that the interrupt pin is connected to. Power Well: Core

18.6.16 Interrupt Pin (IPIN)—Offset 3Dh

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + 3Dh

Default: 00h

7				4					0
0		0		0		0		0	0
					IPIN				

Bit Range	Default & Access	Field Name (ID): Description
7:0	00h RO/V	Interrupt pin (IPIN): Bits 3:0 reflect the value programmed in the interrupt pin registers in chipset configuration space. Bits 7:4 are hardwired to 0000b. See Chap 6 for value. Power Well: Core

18.6.17 XHC System Bus Configuration 1 (XHCC1)—Offset 40h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:20, F:0] + 40h

Default: 000000FDh

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	1
0	0	0	0	0	0	0	0	1

ACCTRL	ECO1	RMTASERR	URD	URRE	IIL1E	XHCIL1E	D3IL1E	PCPWT
								SWAXHCI
								L23HRAWC
								UTAGCP
								UDAGCNP
								UDAGCCP
								UDAGC

Bit Range	Default & Access	Field Name (ID): Description
31	0b RW/O	Access Control (ACCTRL): This bit is used by BIOS to lock/unlock lockable bits. When set to '1' the write access to bits locked by this bit is disabled (locked state). When set to '0', the write access to bit locked by this bit is enabled (unlocked state). Writable once after platform reset. Power Well: Core
30:25	00h RW	ECO1: ECO bits are used during silicon bringup for FIBing. NOT for EDS Power Well: Core
24	0b RW	Master/Target Abort SERR (RMTASERR): When set, it allows the out-of-band error reporting from the xHCI Controller to be reported as SERR# (if SERR# reporting is enabled) and thus set the STS.SSE bit. Power Well: Core
23	0b RW/C	Unsupported Request Detected (URD): Set the HW when xHCI Controller received an unsupported request posted cycle. Cleared by SW when the bit is written with value of '1'. Power Well: Core
22	0b RW	Unsupported Request Report Enable (URRE): When set this bit allows the URD bit to be reported as SERR# (if SERR# reporting is enabled) and thus set the STS.SSE bit. Power Well: Core
21:19	000b RW	Inactivity Initiated L1 Enable (IIL1E): If programmed to non-zero, it allows L1 power managed to be enabled after the time-out period specified. 000: Disabled 001: 32 bb_cclk 010: 64 bb_cclk 011: 128 bb_cclk 100: 256 bb_cclk 101: 512 bb_cclk 110: 1024 bb_cclk 111: 131072 bb_cclk Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
18	0b RW	XHC Initiated L1 Enable (XHCIL1E): If set, allow the XHC initiated L1 power mangement to be enabled. Power Well: Core
17	0b RW	D3 Initiated L1 Enable (D3IL1E): If set, allow PCI device state D3 initiated L1 power managment to be enables. This bit can only be set if the XHCI L1 Override P2 chicken bit is set. Power Well: Core
16:12	00h RW	Periodic Complete Pre Wake Time (PCPWT): signal . This allows for platform wake time before the next scheduled periodic transaction. The value programmed in this field represents the # of bytes consumed in the current micro-frame which is required to allow for the periodic complete to de-assert. This allows for a programmable time to cause the periodic complete to de-assert prior to the start of the next micro-frame. Register Format: Bits (16:12) represnets the # of bytes remaining with a 256B granularity. Periodic Complete will de-assert if the bytes consumed in the current micro-frame is less Power Well: Core
11	0h RW	SW Assisted xHC Idle (SWAXHCI): This bit being set will indicate xHC idleness (through SW means), which must be a '1' to allow L1 entry, and subsequently allow backbone clock to be gated. This bit is to be set by Intel xHCI driver after checking that the xHCI Controller will stay in idle state for a significant period of time, e.g. all ports disconnected. This bit can be cleared under the following conditions (see SWAXHCI Policy bits in xHC System Bus Configuration 2 register): n SW: SW could write 0 to clear this bit. n HW: HW, under policy control, will clear this bit on an MMIO access to the Host Controller. n HW: HW, under policy control, will clear this bit when HW exits Idle state. Power Well: Core
10:8	000b RW	L23 to Host Reset Acknowledge Wait Count (L23HRAWC): If programmed to non zero, it allows a wait period after the L23 PHY has shutdown before returning host reset acknowledge to PMC. 000: Disabled 001: 128 bb_cclk 010: 256 bb_cclk 011: 512 bb_cclk 100: 1024 bb_cclk 101: 2048 bb_cclk 110: 4096 bb_cclk 111: 131072 bb_cclk Power Well: Core
7:6	11b RW	Upstream Type Arbiter Grant Count Posted (UTAGCP): Grant count for IOSF upstream L2 request type arbiter for posted type Power Well: Core
5:4	11b RW	Upstream Type Arbiter Grant Count Non Posted (UDAGCNP): Grant count for IOSF upstream L2 type arbiter for non-posted type Power Well: Core
3:2	11b RW	Upstream Type Arbiter Grant Count Completion (UDAGCCP) (UDAGCCP): Grant count for IOSF upstream L2 type arbiter for completion type Power Well: Core
1:0	01b RW	Upstream Device Arbiter Grant Count (UDAGC) (UDAGC): Grant count for IOSF upstream L1 device arbiter Power Well: Core

18.6.18 XHC System Bus Configuration 2 (XHCC2)—Offset 44h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:20, F:0] + 44h

Default: 0003C000h

31		28				24				20				16				12				8				4				0

OCCFGDONE		ECO1				DREQBCC				IDMA_RDREQSZCTRL				XHCUPRDROE				IOSFSRAD				UNPPA				SWAXHCIP				RAWDD				WAWDE				SWACXIHCB				SWADMILLIHB				L1FP2CGWC				RDREQSZCTRL			

Bit Range	Default & Access	Field Name (ID): Description
31	0b RW/O	OC Configuration Done (OCCFGDONE): This bit is used by BIOS to prevent spurious switching during OC configuration. Any write this register bit will cause it to set. It must be set by BIOS after configuration of the OC mapping bits is complete. Once this bit is set, OC mapping shall not be changed by SW. Power Well: SUS
30:26	00h RW	ECO1: NOT for EDS ECO bits are used during silicon bringup for FIBing. Power Well: Core
25	0b RW	DMA Request Boundary Crossing Control (DREQBCC): This bit controls the boundary crossing limit of each Read/Write Request. 0: 4KB 1: 64B Power Well: Core
24:22	0h RW	IDMA Read Request Size Control (IDMA_RDREQSZCTRL): Read Request Size Control: This bit controls the maximum size of each Read Request. 000: 128B 001: 256B 011 - 110: Reserved 111: 64B Power Well: Core
21	0b RW	XHC Upstream Read Relaxed Ordering Enable (XHCUPRDROE): This policy controls the Relaxed Ordering attribute for upstream reads. 0 - xHC will clear RO for all upstream read requests. 1 - xHC will set RO for all upstream read requests. Power Well: Core
20	0b RW	IOSF Sideband Register Access Disable (IOSFSRAD): When set, it disables the IOSF sideband interface from accepting any host space register access. Power Well: Core
19:14	0Fh RW	Upstream Non-Posted Pre-Allocation (UNPPA): This field reserves data sizes, in 64 byte chunks, of the downstream completion resource. This value is zero based. 000000 - 111111: Pre-allocate 64 bytes - 4096 bytes If set greater than the default allows over-allocation If set less than default allows under-allocation Only allowed to be programmed when BME = 0 and no outstanding downstream completion Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
13:12	00b RW	SW Assisted xHC Idle Policy (SWAXHCIP): Note: Irrespective of the setting of this field, SW write of 0 to SWAXHCI will clear the bit. 00b (default): xHC HW clears SWAXHCI bit upon: n MMIO access to Host Controller OR n xHC HW exits Idle state 01b: xHC HW does not autonomously clear SWAXHCI bit. The bit could be cleared only by SW. 10b: xHC HW clears SWAXHCI upon MMIO access to Host Controller. xHC HW exit from Idle state will not clear SWAXHCI. 11b: Reserved Power Well: Core
11	0h RW	MMIO Read After MMIO Write Delay Disable (RAWDD): This field controls delay on MMIO Read after MMIO Write. 0b (Default): Delay MMIO Read after MMIO Write 1b: Do not delay MMIO Read after MMIO Write Note that this delay applies after the second of the two DW writes in the case where the IOSF Gasket splits a QW write into two single DW writes to the IP. Power Well: Core
10	0h RW	MMIO Write After MMIO Write Delay Enable (WAWDE): This field controls delay on MMIO Write after previous MMIO Write. 0b (Default): Do not delay MMIO Write after previous MMIO Write 1b: Delay MMIO Write after previous MMIO Write Note that the delay count does not apply on the second of the two DW writes that are generated by IOSF Gasket when it splits a QW write into two. In other words, the second of the two DW writes could happen without any delay with respect to the first DW write. This choice is being made for ease of ECO. The delay count, in this case, will apply after the second of the two DW writes. Power Well: Core
9:8	0h RW	SW Assisted Cx Inhibit (SWACXIH): This field controls how the DMI L1 inhibit signal from USB3 to PMC will behave. 00: Never inhibit Cx 01: Inhibit Cx when Isochronous Endpoint is active (PPT Behavior) 10: Inhibit Cx when Periodic Active as defined in 40.4.3.2.1 11: Always inhibit Cx Power Well: Core
7:6	0h RW	SW Assisted DMI L1 Inhibit (SWADMIL1IH): This field controls how the DMI L1 inhibit signal from USB3 to DMI will behave. 00: Never inhibit DMI L1. 01: Inhibit DMI L1 when Isochronous Endpoint is active (PPT Behavior). 10: Inhibit DMI L1 when Periodic Active as defined in 40.4.3.2.1. 11: Inhibit DMI L1 if XHCC1.SWAXHCI = 0. Power Well: Core
5:3	0h RW	L1 Force P2 Clock Gating Wait Count (L1FP2CGWC): If programmed to non zero, it allows L1 force P2 gating off the clock to be delayed after the time-out period specified. If wake up event is detected before the time-out, pclk remains alive and trigger L1 exit as though CPU host is causing the wake, 000: Disabled 001: 128 bb_cclk 010: 256 bb_cclk 011: 512 bb_cclk 100: 1024 bb_cclk 101: 2048 bb_cclk 110: 4096 bb_cclk 111: 131072 bb_cclk Power Well: Core
2:0	000b RW	Read Request Size Control (RDREQSZCTRL): Read Request Size Control: This bit controls the maximum size of each Read Request. 000: 128B 001: 256B 010: 512B 011 - 110: Reserved 111: 64B Power Well: Core

18.6.19 Clock Gating (XHCLKGTEN)—Offset 50h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:20, F:0] + 50h

Default: 00000120h

Bit Range	Default & Access	Field Name (ID): Description
31:29	0h RO	Rsvd2: Reserved Power Well: Core
28	0b RW	Nak&#8217;ing USB2.0 EPs for Backbone Clock Gating and PLL Shutdown (NUEFBCGPS): This field controls whether Naking USB2.0 EPs, once in Naking low priority schedule, should be considered as active for the considerations for backbone clock gating and PLL shutdown or not. 0: Naking USB2.0 EPs are not considered to be active for Backbone Clock Gating and PLL Shutdown evaluation. 1: Naking USB2.0 EPs are considered to be active for Backbone clock gating and PLL shutdown evaluation. Power Well: Core
27	0b RW	SRAM Power Gate Enable (SRAMPGTEN): This register enables the SRAM Power Gating when PLL shutdown conditions for all clock domains have been met 0 - Disallow SRAM Power Gating. 1 - Allow SRAM Power Gating Power Well: Core
26	0h RW	SS Link PLL Shutdown Enable (SSLSE): This register enables the SS P3 state to be exposed to PXP PLL Shutdown conditions on behalf of all USB SS Ports ontop of trunk clock gating. 0 - P3 state NOT allowed to result in PXP PLL shutdown. 1- P3 state allowed to result in PXP PLL shutdown Power Well: Core
25	0h RW	USB2 PLL Shutdown Enable (USB2PLLSE): When set, this bit allows USB2 PLL to be shutdown when HS Link trunk clock is gated, and xHC can tolerate PLL spin up time for subsequent clock request. Note: if USB2 PLL Shutdown Disable Fuse is '1', hardware will always see '0' as an output from this register. BIOS reading this register should always return the correct value. Power Well: Core
24	0h RW	IOSF Sideband Trunk Clock Gating Enable (IOSFSTCGE): When set, this bit allows the IOSF sideband clock trunk to be gated when idle conditions are met. Power Well: Core
23:20	0h RW	HS Backbone PXP Trunk Clock Gate Enable (HSTCGE): This register determines the HS Ux state(s) which will be exposed to Backbone PXP trunk gating of core clock. Uy is a state allowed to result in trunk gating when ss_tcg_ux_en(x) is asserted. (0) ==) U0 or deeper (1) ==) NA (no support for U1) (2) ==) U2 (L1) or deeper (3) ==) U3 (L2) or deeper Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
19:16	0h RW	SS Backbone PXP Trunk Clock Gate Enable (SSTCGE): This register determines the SS Ux state(s) which will be exposed to Backbone PXP trunk gating of core clock. Uy is a state allowed to result in trunk gating when ss_tcg_ux_en(x) is asserted. (0) ==) U0 or deeper (1) ==) U1 or deeper (2) ==) U2 or deeper (3) ==) U3 or deeper Power Well: Core
15	0h RW	XHC Ignore_EU3S (XHCIGEU3S): This register determines if the xHC will use the EU3S as a condition to allow for Frame timer gating. 0 - xHC may allow frame timer to be gated when EU3S is set and all ports are in the required state. 1 - xHC may allow frame timer to be gated regardless of EU3S. Power Well: Core
14	0h RW	XHC Frame Timer Clock Shutdown Enable (XHCFTCLKSE): This register determines if the xHC will allow the frame timer clock to be gated. 0 - xHC will not allow ICC PLL 96MHz output to be shutdown thus keeping the frame timer running. 1 - xHC will allow ICC PLL 96MHz output to be shutdown under specific conditions. Power Well: Core
13	0h RW	XHC Backbone PXP Trunk Clock Gate In Presence of ISOCH EP (XHCBBTCGIPISO): This register controls the policy on allowing Backbone PXP trunk clock gate in the presence of IDLE ISOCH EP s with active DB. Allows the periodic active to be used in enabling Backbone PXP trunk clock gating of core clock. 0 Trunk gate of core clock is not allowed when ISOCH EP DB is set and ISOCH EP s are idle. 1 Allow trunk gate of core clock when ISOCH EP DB is set and ISOCH EP s are idle. Power Well: Core
12	0h RW	XHC HS Backbone PXP Trunk Clock Gate U2 non RWE (XHCHSTCGU2NRWE): This register controls the policy on allowing Backbone PXP trunk gating of core clock when there is atleast 1 non Remote Wake Enabled HS Port in U2. 0 Prevent trunk gate of core clock when a non RWE HS Port is in U2. 1 Allow trunk gate of core clock when a non RWE HS Port is in U2. Power Well: Core
11:10	0h RW	XHC USB2 PLL Shutdown Lx Enable (XHCUSB2PLLSLE): This register determines the HS Link state(s) which will be exposed to USB2 PLL Shutdown conditions on behalf of all USB2 HS Ports. Ly is a state allowed to result in USB2 PLL Shutdown when en(x) is asserted. (0) ==) L1 or deeper (1) ==) L2 or deeper Power Well: Core
9:8	01b RW	HS Backbone PXP PLL Shutdown Ux Enable (HSUXDMIPLLSE): This register determines the Ux state(s) which will be exposed to PXP PLL Shutdown conditions. PLL Shutdown is allowed in: 00b Disabled (Link states shall be disabled for DMI PLL shutdown) 01b U0 or conditions for 10b setting. 10b U2 or conditions for 11b setting. 10b U3, Disconnected, Disabled or Powered-Off. Power Well: Core
7:5	001b RW	SS Backbone PXP PLL Shutdown Ux Enable (SSPLLSUE): This register determines the Ux state(s) which will be exposed to DMI PLL Shutdown conditions. PLL Shutdown is allowed in: 000b Disabled (Link states shall be ignored for DMI PLL shutdown). 001b U0 or conditions for 010b setting 010b U1 or conditions for 011b setting 011b U2 or conditions for 100b setting 100b U3, Disconnected, Disabled or Powered-Off Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
4	0b RW	XHC Backbone Local Clock Gating Enable (XHCBLCGE): When set, this bit allows XHCI Controller IP backbone clock to be locally gated when idle conditions are met. Note: if XHC Dynamic Clock Gating Disable Fuse is '1', hardware will always see '0' as an output from this register. BIOS reading this register should always return the correct value. Power Well: Core
3	0b RW	HS Link Trunk Clock Gating Enable (HSLTCGE): When set, this bit allows High Speed Link control's 480 MHz and its 48/60 MHz link clock trunk to be gated when idle conditions are met. Note: if XHC Dynamic Clock Gating Disable Fuse is '1', hardware will always see '0' as an output from this register. BIOS reading this register should always return the correct value. BIOS need to query fuses to see if HW is enabled. Power Well: Core
2	0b RW	SS Link Trunk Clock Gating Enable (SSLTCGE): When set, this bit allows the SuperSpeed Link control's 250 MHz and its divided 125 MHz link clock trunk to be gated when idle conditions are met. Note: if XHC Dynamic Clock Gating Disable Fuse is '1', hardware will always see '0' as an output from this register. BIOS reading this register should always return the correct value. BIOS need to query fuses to see if HW is enabled. Power Well: Core
1	0b RW	IOSF Backbone Trunk Clock Gating Enable (IOSFBTCGE): When set, this bit allows the IOSF backbone clock trunk to be gated when idle conditions are met. Power Well: Core
0	0b RW	IOSF Gasket Backbone Local Clock Gating Enable (IOSFBLCGE): When set, this bit allows the IOSF Gasket backbone clock to be locally gated when idle conditions are met. Note: if XHC Dynamic Clock Gating Disable Fuse is '1', hardware will always see '0' as an output from this register. BIOS reading this register should always return the correct value. BIOS need to query fuses to see if HW is enabled. Power Well: Core

18.6.20 Audio Time Synchronization (AUDSYNC)—Offset 58h

This 32 bit register is used for audio stream synchronization across different devices. Global signal sample_now captures a value in AUDSYNC register.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:20, F:0] + 58h

Default: 00000000h

31	28	24	20	16	12	8	4	0

Bit Range	Default & Access	Field Name (ID): Description
29:16	0000h RO/V	Captured Frame List Current Index/Frame Number (CMFI): The value in this register is updated in response to sample_now signal. Bits (29:16) reflect state of bits (13:0) of FRINDEX Power Well: Core
15:13	0h RO	Rsvd1: Reserved. Power Well: Core
12:0	0000h RO/V	Captured Micro-frame BLIF (CMFB): The value is updated in response to sample_now signal and provides information about offset within micro-frame. Captured value represents number of 8 high-speed bit time units from start of micro-frame. At the beginning of micro-frame captured value will be 0 and increase to maximum value at the end. Default maximum value is 7499 but it may be changed as result of adjustment done in FLA. Power Well: Core

18.6.21 Serial Bus Release Number (SBRN)—Offset 60h

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + 60h

Default: 30h

7			4				0
0	0	1	1	0	0	0	0
				SBRN			

Bit Range	Default & Access	Field Name (ID): Description
7:0	30h RO	Serial Bus Release Number (SBRN): A value of 30h indicates that this controller follows USB release 3.0. Power Well: SUS

18.6.22 Frame Length Adjustment (FLADJ)—Offset 61h

This feature is used to adjust any offset from the clock source that generates the clock that drives the SOF counter. When a new value is written into these six bits, the length of the frame is adjusted. Its initial programmed value is system dependent based on the accuracy of hardware USB clock and is initialized by system BIOS. This register should only be modified when the HChalted bit in the USBSTS register is a one. Changing value of this register while the host controller is operating yields undefined results.

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

Offset: [B:0, D:20, F:0] + 61h

Default: 20h

7	0	0	1	0	0	0	0

(Size: 8 bits)

Offset: [B:0, D:20, F:0] + 71h

Default: 80h

7				4					0
1	0	0	0	0	0	0	0	0	0
PM_NEXT									

Bit Range	Default & Access	Field Name (ID): Description
7:0	80h RW/L	Next Item Pointer #1 (PM_NEXT): This register defaults to 80h, which indicates that the next capability registers begin at configuration offset 80h. This register is writable when the Access Control bit is set to '0'. This allows BIOS to effectively hide the next capability registers, if necessary. This register should only be written during system initialization before the plug-and-play software has enabled any master-initiated traffic. Values of: 80h implies next capability is MSI 00h implies that MSI capability is hidden. Note: This value is never expected to be programmed. Power Well: Core

18.6.26 Power Management Capabilities (PM_CAP)—Offset 72h

Normally, this register is read-only to report capabilities to the power management software. In order to report different power management capabilities depending on the system in which the Intel PCH is used, the write access to this register is controlled by the Access Control bit (ACCTRL). The value written to this register does not affect the hardware other than changing the value returned during a read. This register is modified and maintained by BIOS

Access Method

15	12	8	4	0
0	0 0 0 0	0 0 0 0	0 0 0 0	1 0 0 0
PME_Status	Data_Scale	Data_Select	PME_En	RSVD
				NSR
				RSVD2
				PowerState

Bit Range	Default & Access	Field Name (ID): Description
15	0b RW/1C	PME_Status: This bit is set when the Intel PCH XHC would normally assert the PME# signal independent of the state of the PME_En bit. Writing a 1 to this bit will clear it and cause the internal PME to deassert (if enabled). Writing a 0 has no effect. This bit must be explicitly cleared by the operating system each time the operating system is loaded. Power Well: SUS
14:13	00b RO	Data_Scale: The Intel PCH hardwires these bits to 00 because it does not support the associated Data register. Power Well: Core
12:9	0h RO	Data_Select: The Intel PCH hardwires these bits to 0000 because it does not support the associated Data register. Power Well: Core
8	0b RW	PME_En: A 1 enables the Intel PCH XHC to generate an internal PME signal when PME_Status is 1. This bit must be explicitly cleared by the operating system each time it is initially loaded. Power Well: SUS
7:4	0h RO	Reserved (RSVD): Reserved. Power Well: Core
3	1b RO	No Soft Reset (NSR):), this bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved. Upon transition from the D3hot to the D0 Initialized state, no additional operating system intervention is required to preserve Configuration Context beyond writing the PowerState bits. Transition from D3hot to D0 by a system or bus segment reset will return to the device state D0 Uninitialized with only PME context preserved if PME is supported and enabled. Power Well: Core
2	0b RO	Reserved (RSVD2): Reserved. Power Well: Core
1:0	00b RW	PowerState: This 2-bit field is used both to determine the current power state of XHC function and to set a new power state. The definition of the field values are: 00b - D0 state 11b - D3hot state If software attempts to write a value of 10b or 01b in to this field, the write operation must complete normally, however, the data is discarded and no state change occurs. When in the D3hot state, the Intel PCH must not accept accesses to the XHC memory range, but the configuration space must still be accessible. Power Well: Core

Data

Bit Range	Default & Access	Field Name (ID): Description
15:0	0000h RW	Data: This 16-bit field is programmed by system software if MSI is enabled. Its content is driven onto the lower word (PCI AD(15:0)) during the data phase of the MSI memory write transaction. The Multiple Message Enable field (bits 6-4 of the Message Control register) defines the number of low order message data bits the function is permitted to modify to generate its system software allocated vectors. For example, a Multiple Message Enable encoding of 010 indicates the function has been allocated four vectors and is permitted to modify message data bits 1 and 0 (a function modifies the lower message data bits to generate the allocated number of vectors). If the Multiple Message Enable field is 000, the function is not permitted to modify the message data. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Rsvd1: Reserved. Power Well: Core
23:14	000h RO/V	Spare Fuses (SPARE): Will be used for VLV2. Power Well: SUS
13:11	000b RO/V	USH DevID (USH_DEVID): LSB bits of USH PCIe Device ID The 3 LSB bits enable defining up to 8 separate USH SKUs if required Power Well: SUS
10	0b RO/V	Debug Device Enable (XDD_EN): 0 : Debug Device is Enabled 1: Debug Device is Disabled Power Well: SUS
9	0h RO/V	SRAM Power Gating Disable (SRAMPWRGTDIS): 0: SRAM Power Gating Enabled 1: SRAM Power Gating Disabled Power Well: SUS
8	0h RO/V	USB2 PLL Shutdown Disable (USB2PLLSDIS): 0: USB2 PLL shutdown enabled 1: USB2 PLL shutdown disabled Power Well: SUS
7	0h RO/V	USB I/O Power Management Disable (USB1OPMDIS): 0: USB2 HW LPM and USB3 HW Ux under XHC enabled 1: USB2 HW LPM and USB3 HW Ux under XHC disabled Power Well: SUS
6	0h RO/V	XHC Dynamic Clock Gating Disable (XHCDCGDIS): 0: USB3 (XHC) dynamic clock gating enabled 1: USB3 (XHC) dynamic clock gating disabled Power Well: SUS
5	0h RO/V	USBr Disable (USBRDIS): 0: USBr enabled 1: USBr disabled Power Well: SUS
4:3	0h RO/V	SS Port Count (SSPRTCNT): This field specifies number of SS ports present. Supported combinations are: 00: 6 SS ports 01: 4 SS ports 10: 2 SS ports 11: 0 SS ports Power Well: SUS
2:1	0h RO/V	HS Port Count (HSPRTCNT): This field specifies number HS ports present. Supported combinations are: 00: 14 HS ports 01: 12 HS ports 10: 10 HS ports 11: N/A (reserved) Power Well: SUS

Access Method

Offset: [B:0, D:20, F:0] + E4h

Bit Range	Default & Access	Field Name (ID): Description
31:4	0000000h RO	Rsvd1: Reserved. Power Well: Core
3:0	0h RW/O	USB2 Port Disable Override (USB2PDO): A '1' in a bit position prevents the corresponding USB2 port from reporting a Device Connection to the XHC. Power Well: SUS

18.6.47 USB3 Port Disable Override (USB3PDO)—Offset E8h

Access Method

Offset: [B:0, D:20, F:0] + E8h

Bit Range	Default & Access	Field Name (ID): Description
31:4	0000000h RO	Rsvd1: Reserved. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
3:0	0h RW/O	USB3 Port Disable Override (USB3PDO): A '1' in a bit position prevents the corresponding USB3 port from reporting a Device Connection to the XHC. Power Well: SUS

18.6.48 USB2 FS/LS Port Staggering Control (FSLSPS)—Offset ECh

The host controller provides a programmable time offset for each FS/LS port. Based on the value programmed in these registers, the controller will inject a fixed delay on each FS or LS transaction initiated on that port.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:20, F:0] + ECh

Default: 0000D8D8h

31				28				24				20				16				12				8				4				0

RSVD1																FSLSPS8				FSLSPS7				FSLSPS6				FSLSPS5				FSLSPS4				FSLSPS3				FSLSPS2				FSLSPS1			

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Rsvd1 (RSVD1): Reserved for Future Use Power Well: Core
15:14	11b RW	FS/LS Stagger Offset for USB2 Port 8 (FSLSPS8): FS/LS Stagger Offset for USB2 Port 8 00: No time offset / Staggering disabled 01: 4ns time offset 10: 8ns time offset 11: 12ns time offset Power Well: Core
13:12	01b RW	FS/LS Stagger Offset for USB2 Port 7 (FSLSPS7): FS/LS Stagger Offset for USB2 Port 7 00: No time offset / Staggering disabled 01: 4ns time offset 10: 8ns time offset 11: 12ns time offset Power Well: Core
11:10	10b RW	FS/LS Stagger Offset for USB2 Port 6 (FSLSPS6): FS/LS Stagger Offset for USB2 Port 6 00: No time offset / Staggering disabled 01: 4ns time offset 10: 8ns time offset 11: 12ns time offset Power Well: Core
9:8	00b RW	FS/LS Stagger Offset for USB2 Port 5 (FSLSPS5): FS/LS Stagger Offset for USB2 Port 5 00: No time offset / Staggering disabled 01: 4ns time offset 10: 8ns time offset 11: 12ns time offset Power Well: Core
7:6	11b RW	FS/LS Stagger Offser for USB2 Port 4 (FSLSPS4): FS/LS Stagger Offset for USB2 Port 4 00: No time offset / Staggering disabled 01: 4ns time offset 10: 8ns time offset 11: 12ns time offset Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
5:4	01b RW	FS/LS Stagger Offset for USB2 Port 3 (FSLSPS3): FS/LS Stagger Offset for USB2 Port 3 00: No time offset / Staggering disabled 01: 4ns time offset 10: 8ns time offset 11: 12ns time offset Power Well: Core
3:2	10b RW	FS/LS Stagger Offset for USB2 Port 2 (FSLSPS2): FS/LS Stagger Offset for USB2 Port 2 00: No time offset / Staggering disabled 01: 4ns time offset 10: 8ns time offset 11: 12ns time offset Power Well: Core
1:0	00b RW	FS/LS Stagger Offset for USB2 Port 1 (FSLSPS1): FS/LS Stagger Offset for USB2 Port 1 00: No time offset / Staggering disabled 01: 4ns time offset 10: 8ns time offset 11: 12ns time offset Power Well: Core

18.6.49 DFT 1 (DFT1)—Offset F0h

Not for EDS

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:20, F:0] + F0h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
SSDFTCRC					Rsvd1	SSDFTLMSEL	SSDFTCRCSEL	SSDFTCPS

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Super Speed DFT CRC (SSDFTCRC): These register bits contain the value of Super Speed DFT CRC Power Well: Core
15:8	00h RO	Rsvd1: Reserved. Power Well: Core
7	0h RW	Super Speed DFT LFPS Mode Select (SSDFTLMSEL): This bit selects the Super Speed DFT LFPS mode, and will only take effect when Super Speed HBP mode is enabled. 0b: HBP logic will internally loopback TX LFPS as RX LFPS and AFE RX LFPS path to the controller is disconnected. 1b: RX LFPS path works normally Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
1	0b RW	Loopback Pattern (UTMILPBKPATSEL): Near end loopback pattern generation type: 0b: Fixed pattern 1b: USB2 test packet Power Well: Core
0	0b RW	Loopback Type (UTMILPBKTYPE): Loopback Type in test mode. This signal selects between DNELB and ANELB, and will only take effect if DTUTMILPBKEN is set. 0b: Digital Near-End Loopback (DNELB) 1b: Analog Near-End Loopback (ANELB) Note: Analog Far-End Loopback (AFELB) is not supported Power Well: Core

18.7.1 Capability Registers Length (CAPLENGTH)—Offset 0h

This register is used as an offset to add to register base, to find the beginning of the Operational Register Space. This register is modified and maintained by BIOS.

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

Offset: [MBAR] + 0h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 80h

7	4	0
1	0	0
CAPLENGTH		

Bit Range	Default & Access	Field Name (ID): Description
7:0	80h RW/L	Capability Registers Length (CAPLENGTH): This field is used as an offset to add to register base, to find the beginning of the Operational Register Space. Power Well: Core

18.7.2 Host Controller Interface Version Number (HCIVERSION)—Offset 2h

This is a two-byte register containing a BCD encoding of the xHCI specification revision number supported by this host controller. The most significant byte of this register represents a major revision, and the least significant bit is the minor revision, e.g. 0100h corresponds to xHCI version 1.0. This register is modified and maintained by BIOS.

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

Offset: [MBAR] + 2h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 0100h

0	0	0	1	0
0	0	0	0	0
0	0	0	0	0

HCVERSION

Bit Range	Default & Access	Field Name (ID): Description
15:0	0100h RO	Host Controller Interface Version Number (HCVERSION): This is a two-byte field containing a BCD encoding of the xHCI specification revision number supported by this host controller. The most significant byte of this field represents a major revision, and the least significant bit is the minor revision, e.g. 0100h corresponds to xHCI version 1.0. Power Well: Core

18.7.3 Structural Parameters 1 (HCSPARAMS1)—Offset 4h

This register defines basic structural parameters supported by this xHC implementation: Number of Device Slots support, Interrupters, Root Hub ports, etc. This register is modified and maintained by BIOS.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 4h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 07000820h

31	28	24	20	16	12	8	4	0

0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0

MaxPorts

Rsvd1

MaxIntrs

MaxSlots

Bit Range	Default & Access	Field Name (ID): Description
31:24	07h RO	Number of Ports (MaxPorts): This field specifies the maximum Port Number value, i.e the highest number of Port Register Sets that are addressable in the Operational Register Space (refer to the xHCI for USB specification). Valid values are in the range of 1h to FFh. The value in this field shall reflect the maximum Port Number value assigned by an <i>xHCI Supported Protocol Capability</i> , described in the xHCI for USB specification. Software shall refer to these capabilities to identify whether a specific Port Number is valid, and the protocol supported by the associated Port Register Set. Power Well: Core
23:19	00h RW/L	Rsvd1: Reserved. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
25:8	00000h RW/L	Rsvd1: Reserved. Power Well: Core
7:4	5h RW/L	Event Ring Segment Table Max (ERSTMax): Valid values are 0-15. This field determines the maximum value supported by the <i>Event Ring Segment Table Base Size</i> registers (5.5.2.3.1), where The maximum number of Event Ring Segment Table entries = $2^{(ERST\ Max)}$ e.g. if the ERST Max = 7, then the xHC <i>Event Ring Segment Table(s)</i> supports up to 128 entries, if ERST Max = 15, then 32K entries, etc. Power Well: Core
3:0	4h RW/L	Isochronous Scheduling Threshold (IST): The value in this field indicates to system software the minimum distance (in time) that it is required to stay ahead of the host controller while adding TRBs, in order to have the host controller process them at the correct time. The value shall be specified in terms of number of frames/microframes. If bit [3] of IST is cleared to '0', software can add a TRB no later than IST[2:0] microframes before that TRB is scheduled to be executed. If bit [3] of IST is set to '1', software can add a TRB no later than IST[2:0] frames before that TRB is scheduled to be executed. Refer to the xHCI for USB specification for details on how software uses this information for scheduling isochronous transfers. Power Well: Core

18.7.5 Structural Parameters 3 (HCSPARAMS3)—Offset Ch

This register defines link exit latency related structural parameters. This register is modified and maintained by BIOS.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + Ch

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 00040001h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	1
U2DEL				Rsvd1				U1DEL

Bit Range	Default & Access	Field Name (ID): Description
31:16	0004h RW/L	U2 Device Exit Latency (U2DEL): Worst case latency to transition from U2 to U0. Applies to all root hub ports. The following are permissible values: 0000h = Zero 0001h = Less than 1 s 0002h = Less than 2 s 07FFh = Less than 2047 s. 0800-FFFFh = Reserved Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
15:8	00h RW/L	Rsvd1: Reserved. Power Well: Core
7:0	01h RW/L	U1 Device Exit Latency (U1DEL): Worst case latency to transition a root hub Port Link State (PLS) from U1 to U0. Applies to all root hub ports. The following are permissible values: 01h = Less than 1 s 02h = Less than 2 s ... 0Ah = Less than 10 s 0B-FFh = Reserved Power Well: Core

18.7.6 Capability Parameters (HCCPARAMS)—Offset 10h

The default values for all fields in this register are implementation dependent. This register defines optional capabilities supported by the xHCI. This register is modified and maintained by BIOS.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 10h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 200071E1h

31	28	24	20	16	12	8	4	0

xECP				MaxPSASize		Rsvd1	PAE	NSS
							LTC	LHRC
							PIND	PPC
								CSZ
								BNC
								AC64

Bit Range	Default & Access	Field Name (ID): Description
31:16	2000h RW/L	xHCI Extended Capabilities Pointer (xECP): This field indicates the existence of a capabilities list. The value of this field indicates a relative offset, in 32-bit words, from Base to the beginning of the first extended capability. For example, using the offset of Base is 1000h and the xECP value of 0068h, we can calculate the following effective address of the first extended capability: 1000h + (0068h ((2) -) 1000h + 01A0h -) 11A0h a. This is not tightly coupled with the USBBASE address register mapping control. Power Well: Core
15:12	7h RW/L	Maximum Primary Stream Array Size (MaxPSASize): This field identifies the maximum size Primary Stream Array that the xHC supports. The Primary Stream Array size = 2^(MaxPSASize+1). Valid MaxPSASize values are 0 to 15, where 0 indicates that Streams are not supported. Power Well: Core
11:9	0h RW/L	Rsvd1: Reserved. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
8	1b RW/L	Parse All Event Data (PAE): This flag indicates whether the host controller implementation parses all Event Data TRBs while advancing to the next TD after a Short Packet, or skips all but the first Event Data TRB. A 1 in this bit indicates that all Event Data TRBs are parsed. A 0 in this bit indicates that only the first Event Data TRB is parsed. Refer to the xHCI for USB specification. Power Well: Core
7	1b RW/L	No Secondary SID Support (NSS): This flag indicates whether the host controller implementation supports Secondary Stream IDs. A 1 in this bit indicates that Secondary Stream ID decoding is not supported. A 0 in this bit indicates that Secondary Stream ID decoding is supported. Refer to the xHCI for USB specification. Power Well: Core
6	1b RW/L	Latency Tolerance Messaging Capability (LTC): This flag indicates whether the host controller implementation supports Latency Tolerance Messaging (LTM). A 1 in this bit indicates that LTM is supported. A 0 in this bit indicates that LTM is not supported. Refer to the xHCI for USB specification. Power Well: Core
5	1b RW/L	Light HC Reset Capability (LHRC): This flag indicates whether the host controller implementation supports a Light Host Controller Reset. A 1 in this bit indicates that Light Host Controller Reset is supported. A 0 in this bit indicates that Light Host Controller Reset is not supported. The value of this flag affects the functionality of the <i>Light Host Controller Reset</i> (LHCRST) flag in the USB_CMD register. Refer to the xHCI for USB specification. Power Well: Core
4	0b RW/L	Port Indicators (PIND): This bit indicates whether the xHC root hub ports support port indicator control. When this bit is a 1, the port status and control registers include a read/ writeable field for controlling the state of the port indicator. Refer to the xHCI for USB specification for the definition of the <i>Port Indicator Control</i> field. Power Well: Core
3	0b RO	Port Power Control (PPC): This flag indicates whether the host controller implementation includes port power control. A 1 in this bit indicates the ports have port power switches. A 0 in this bit indicates the port does not have port power switches. The value of this flag affects the functionality of the PP flag in each port status and control register. See the xHCI for USB specification. Power Well: Core
2	0b RW/L	Context Size (CSZ): If this bit is set to 1, then the xHC uses 64 byte Context data structures. If this bit is cleared to 0, then the xHC uses 32 byte Context data structures. Note: This flag does <i>not</i> apply to Stream Contexts. Power Well: Core
1	0b RW/L	BW Negotiation Capability (BNC): This flag identifies whether the xHC has implemented the Bandwidth Negotiation. Values for this flag have the following interpretation: 0 = BW Negotiation not implemented 1 = BW Negotiation implemented Refer to the xHCI for USB specification for more information on Bandwidth Negotiation. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
9	0b RW	Controller Restore State (CRS): When set to 1, and HCHalted (HCH) = 1, then the xHC shall perform a Restore State operation and restore its internal state. When set to 1 and <i>Run/Stop</i> (R/S) = 1 or <i>HCHalted</i> (HCH) = 0, or when cleared to 0, no Restore State operation shall be performed. This flag always returns 0 when read. Refer to the <i>Restore State Status</i> (RSS) flag in the USBSTS register for information on Restore State completion. Refer to the xHCI for USB specification, for more information. Note that undefined behavior may occur if a Restore State operation is initiated while <i>Save State Status</i> (SSS) = 1. When this register is exposed by a Virtual Function (VF), this bit only controls restoring the state of the xHC instance presented by the selected VF. Refer to the xHCI for USB specification for more information. Power Well: Core
8	0b RW	Controller Save State (CSS): When written by software with 1 and HCHalted (HCH) = 1, then the xHC shall save any internal state that may be restored by a subsequent Restore State operation. When written by software with 1 and HCHalted (HCH) = 0, or written with 0, no Save State operation shall be performed. This flag always returns 0 when read. Refer to the <i>Save State Status</i> (SSS) flag in the USBSTS register for information on Save State completion. Refer to the xHCI for USB specification for more information on xHC Save/Restore operation. Note that undefined behavior may occur if a Save State operation is initiated while <i>Restore State Status</i> (RSS) = 1. When this register is exposed by a Virtual Function (VF), this bit only controls saving the state of the xHC instance presented by the selected VF. Refer to the xHCI for USB specification for more information. Power Well: Core
7	0b RW	Light Host Controller Reset (LHCRST): Optional normative. If the <i>Light HC Reset Capability</i> (LHRC) bit in the HCCPARAMS register is 1, then this flag allows the driver to reset the xHC without affecting the state of the ports. A system software read of this bit as 0 indicates the <i>Light Host Controller Reset</i> has completed and it is safe for software to re-initialize the xHC. A software read of this bit as a 1 indicates the <i>Light Host Controller Reset</i> has not yet completed. If not implemented, a read of this flag shall always return a 0. All registers in the Aux Power well shall maintain the values that had been asserted prior to the Light Host Controller Reset. (Refer to the xHCI for USB specification for more information.) When this register is exposed by a Virtual Function (VF), this bit only generates a Light Reset to the xHC instance presented by the selected VF, e.g. disabling the VF's device slots and setting the associated VF Run bit to Stopped. Refer to the xHCI for USB specification for more information. Power Well: Core
6:4	0h RO	Rsvd1: Reserved. Power Well: Core
3	0b RW	Host System Error Enable (HSEE): When this bit is a 1, and the HSE bit in the USBSTS register is a 1, the xHC shall assert out-of-band error signaling to the host. The signaling is acknowledged by software clearing the HSE bit. Refer to the xHCI for USB specification for more information. When this register is exposed by a Virtual Function (VF), the effect of the assertion of this bit on the Physical Function (PF0) is determined by the VMM. Refer to the xHCI for USB specification for more information. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
2	0b RW	Interrupter Enable (INTE): This bit provides system software with a means of enabling or disabling the host system interrupts generated by Interrupters. When this bit is a 1, then Interrupter host system interrupt generation is allowed, i.e. the xHC shall issue an interrupt at the next interrupt threshold if the host system interrupt mechanism (e.g. MSI, MSIX, etc.) is enabled. The interrupt is acknowledged by a host system interrupt specific mechanism. When this register is exposed by a Virtual Function (VF), this bit only enables the set of Interrupters assigned to the selected VF. Power Well: Core
1	0b RW	Host Controller Reset (HCRST): This control bit is used by software to reset the host controller. The effects of this bit on the xHC and the Root Hub registers are similar to a Chip Hardware Reset. When software writes a 1 to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on the USB is immediately terminated. A USB reset shall not be driven on USB2 downstream ports, however a Hot or Warm Reset shall be initiated on USB3 Root Hub downstream ports. PCI Configuration registers are not affected by this reset. All operational registers, including port registers and port state machines are set to their initial values. Software shall reinitialize the host controller, as described in the xHCI for USB specification, in order to return the host controller to an operational state. This bit is cleared to 0 by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing a 0 to this bit and shall not write any xHC Operational or Runtime registers until while HCRST is 1. Note, the completion of the xHC reset process is not gated by the Root Hub port reset process. Software shall not set this bit to 1 when the HCHalted (HCH) bit in the USBSTS register is a 0. Attempting to reset an actively running host controller may result in undefined behavior. When this register is exposed by a Virtual Function (VF), this bit only resets the xHC instance presented by the selected VF. Refer to the xHCI for USB specification for more information. Power Well: Core
0	0b RW	Run/Stop (RS): 1 = Run 0 = Stop When set to a 1, the xHC proceeds with execution of the schedule. The xHC continues execution as long as this bit is set to a 1. When this bit is cleared to 0, the xHC completes any current or queued commands or TDs, and any USB transactions associated with them, then halts. Refer to section 5.4.1.1 for more information on how R/S shall be managed. The xHC shall halt within 16 ms. after software clears the Run/Stop bit if the above conditions have been met. The HCHalted (HCH) bit in the USBSTS register indicates when the xHC has finished its pending pipelined transactions and has entered the stopped state. Software shall not write a 1 to this flag unless the xHC is in the Halted state (i.e. HCH in the USBSTS register is 1). Doing so may yield undefined results. Writing a 0 to this flag when the xHC is in the Running state (i.e. HCH = 0) and any Event Rings are in the Event Ring Full state (refer to section 4.9.4) may yield undefined results. When this register is exposed by a Virtual Function (VF), this bit only controls the run state of the xHC instance presented by the selected VF. Power Well: Core

18.7.10 USB Status (USBSTS)—Offset 84h

This register indicates pending interrupts and various states of the Host Controller. The status resulting from a transaction on the serial bus is not indicated in this register. Software sets a bit to '0' in this register by writing a '1' to it (RW1C). Refer to specification *eXtensible Host Controller Interface for Universal Serial Bus (xHCI)* for additional information concerning USB interrupt conditions.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 84h

Bit Range	Default & Access	Field Name (ID): Description
31:13	00000h RO	Rsvd3: Reserved. Power Well: Core
12	0b RO	Host Controller Error (HCE): This bit is not preset in HC, this is deviation from xHCI 1.0 spec. Power Well: Core
11	0b RO	Controller Not Ready (CNR): This is deviation from xHCI 1.0 spec. Power Well: Core
10	0b RW/C	Save/Restore Error (SRE): If an error occurs during a Save or Restore operation, this bit shall be set to 1. This bit shall be cleared to 0 when a Save or Restore operation is initiated or when written with 1. Refer to the xHCI for USB specification for more information. When this register is exposed by a Virtual Function (VF), the VMM determines the state of this bit as a function of the Save/Restore completion status for the selected VF. Refer to the xHCI for USB specification for more information. Power Well: Core
9	0b RO	Restore State Status (RSS): When the Controller Restore State (CRS) flag in the USBCMD register is written with 1 this bit shall be set to 1 and remain 1 while the xHC restores its internal state. When the Restore State operation is complete, this bit shall be cleared to 0. Refer to the xHCI for USB specification for more information. When this register is exposed by a Virtual Function (VF), the VMM determines the state of this bit as a function of the restoring the state for the selected VF. Refer to the xHCI for USB specification for more information. Power Well: Core
8	0b RO	Save State Status (SSS): When the <i>Controller Save State</i> (CSS) flag in the USBCMD register is written with 1, this bit shall be set to 1 and remain 1 while the xHC saves its internal state. When the Save State operation is complete, this bit shall be cleared to 0. Refer to the xHCI for USB specification for more information. When this register is exposed by a Virtual Function (VF), the VMM determines the state of this bit as a function of the saving the state for the selected VF. Refer to the xHCI for USB specification for more information. Power Well: Core
7:5	0h RO	Rsvd2: Reserved. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
4	0b RW/C	Port Change Detect (PCD): The xHC sets this bit to a 1 when any port has a change bit transition from a 0 to a 1. This bit is allowed to be maintained in the Aux Power well. Alternatively, it is also acceptable that on a D3 to D0 transition of the xHC, this bit is loaded with the OR of all of the PORTSC change bits. Refer to the xHCI for USB specification for more information. This bit provides system software an efficient means of determining if there has been Root Hub port activity. Refer to the xHCI for USB specification for more information. When this register is exposed by a Virtual Function (VF), the VMM determines the state of this bit as a function of the Root Hub Ports associated with the Device Slots assigned to the selected VF. Refer to the xHCI for USB specification for more information. Power Well: Core
3	0b RW/C	Event Interrupt (EINT): The xHC sets this bit to 1 when the <i>Interrupt Pending</i> (IP) bit of any Interrupter transitions from 0 to 1. Refer to the xHCI for USB specification for usage information. Software that uses <i>EINT</i> shall clear it prior to clearing any IP flags. A race condition may occur if software clears the <i>IP</i> flags, then clears the <i>EINT</i> flag, and between the operations another <i>IP</i> 0 to '1' transition occurs. In this case, the new IP transition shall be lost. When this register is exposed by a Virtual Function (VF), this bit is the logical 'OR' of the IP bits for the Interrupters assigned to the selected VF. And it shall be cleared to 0 when all associated interrupter IP bits are cleared, i.e. all the VFs Interrupter Event Ring(s) are empty. Refer to the xHCI for USB specification for more information. Power Well: Core
2	0b RW/C	Host System Error (HSE): The xHC sets this bit to 1 when a serious error is detected, either internal to the xHC or during a host system access involving the xHC module. (In a PCI system, conditions that set this bit to 1 include PCI Parity error, PCI Master Abort, and PCI Target Abort.) When this error occurs, the xHC clears the Run/Stop (R/S) bit in the USBCMD register to prevent further execution of the scheduled TDs. If the HSEE bit in the USBCMD register is a 1, the xHC shall also assert out-of-band error signaling to the host. Refer to the xHCI for USB specification for more information. When this register is exposed by a Virtual Function (VF), the assertion of this bit affects all VFs and reflects the Host System Error state of the Physical Function (PF0). Refer to the xHCI for USB specification for more information. Power Well: Core
1	0b RO	Rsvd1: Reserved. Power Well: Core
0	1b RO	HCHalted (HCH): This bit is a 0 whenever the <i>Run/Stop</i> (R/S) bit is a 1. The xHC sets this bit to 1 after it has stopped executing as a result of the <i>Run/Stop</i> (R/S) bit being cleared to 0, either by software or by the xHC hardware (e.g. internal error). If this bit is '1', then SOFs, microSOFs, or Isochronous Timestamp Packets (ITP) shall not be generated by the xHC, and any received Transaction Packet shall be dropped. When this register is exposed by a Virtual Function (VF), this bit only reflects the Halted state of the xHC instance presented by the selected VF. Refer to the xHCI for USB specification for more information. Power Well: Core

18.7.11 Page Size (PAGESIZE)—Offset 88h

The default value for this register is implementation dependent.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 88h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 00000001h

Rsvd1				PAGESIZE				

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Rsvd1: Reserved. Power Well: Core
15:0	0001h RO	Page Size (PAGESIZE): This field defines the page size supported by the xHC implementation. This xHC supports a page size of $2^{(n+12)}$ if bit n is Set. For example, if bit 0 is Set, the xHC supports 4k byte page sizes. For a Virtual Function, this register reflects the page size selected in the <i>System Page Size</i> field of the SR-IOV Extended Capability structure. For the Physical Function 0, this register reflects the implementation dependent default xHC page size. Various xHC resources reference PAGESIZE to describe their minimum alignment requirements. The maximum possible page size is 128M. Power Well: Core

18.7.12 Device Notification Control (DNCTRL)—Offset 94h

This register is used by software to enable or disable the reporting of the reception of specific USB Device Notification Transaction Packets. A *Notification Enable* (Nx, where x = 0 to 15) flag is defined for each of the 16 possible device notification types. If a flag is set for a specific notification type, a Device Notification Event shall be generated when the respective notification packet is received. After reset, all notifications are disabled. Refer to specification *eXtensible Host Controller Interface for Universal Serial Bus (xHCI)*. This register shall be written as a Dword. Byte writes produce undefined results.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 94h

Bit Range	Default & Access	Field Name (ID): Description
2	0b RW/S	Command Abort (CA): Writing a '1' to this bit shall immediately terminate the currently executing command, stop the Command Ring, and generate a Command Completion Event with the Completion Code set to Command Ring Stopped. Refer to the xHCI for USB specification for more information on aborting a command. The next write to the <i>Host Controller Doorbell</i> with <i>DB Reason</i> field set to <i>Host Controller Command</i> shall restart the Command Ring operation. Writes to this flag are ignored by the xHC if <i>Command Ring Running</i> (CCR) = '0'. Reading this bit always returns '0'. Power Well: Core
1	0b RW/S	Command Stop (CS): Writing a '1' to this bit shall stop the operation of the Command Ring after the completion of the currently executing command, and generate a <i>Command Completion Event</i> with the <i>Completion Code</i> set to <i>Command Ring Stopped</i> and the <i>Command TRB Pointer</i> set to the current value of the <i>Command Ring Dequeue Pointer</i>. Refer to the xHCI for USB specification for more information on stopping a command. The next write to the <i>Host Controller Doorbell</i> with <i>DB Reason</i> field set to <i>Host Controller Command</i> shall restart the Command Ring operation. Writes to this flag are ignored by the xHC if <i>Command Ring Running</i> (CCR) = '0'. Reading this bit shall always return '0'. Power Well: Core
0	0b RW	Ring Cycle State (RCS): This bit identifies the value of the xHC <i>Consumer Cycle State</i> (CCS) flag for the TRB referenced by the <i>Command Ring Pointer</i>. Refer to the xHCI for USB specification for more information. Writes to this flag are ignored if <i>Command Ring Running</i> is '1'. If the CRCR is written while the Command Ring is stopped (CCR = '0'), then the value of this flag shall be used to fetch the first Command TRB the next time the <i>Host Controller Doorbell</i> register is written with the <i>DB Reason</i> field set to <i>Host Controller Command</i>. If the CRCR is <i>not</i> written while the Command Ring is stopped (CCR = '0'), then the Command Ring shall begin fetching Command TRBs using the current value of the <i>Internal Command Ring CCS</i> flag. Reading this flag always returns '0'. Power Well: Core

18.7.14 Command Ring High (CRCR_HI)—Offset 9Ch

The Command Ring Control Register provides Command Ring control and status capabilities, and identifies the address and Cycle bit state of the Command Ring Dequeue Pointer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

18.7.19 Port 1 Power Management Status and Control USB2 (PORTPMSC1USB2)—Offset 484h

This register is in the Aux Power well. It is only reset by platform hardware during a cold reset or in response to a *Host Controller Reset* (HCRST). The USB2 Port Power Management Status and Control register provides the USB2 LPM parameters necessary for the xHC to generate a LPM Token to the downstream device.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 484h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 00000000h

31				28				24				20				16				12				8				4				0			
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0			
PTC				Rsvd1												HLE				L1DS				HIRD				RWE				L1S			

Bit Range	Default & Access	Field Name (ID): Description
31:28	0h RW	Port Test Control (PTC): Note: This register is sticky. Power Well: SUS
27:17	000h RO	Rsvd1: Reserved. Power Well: Core
16	0b RO	Hardware LPM Enable (HLE): Reserved. Power Well: SUS
15:8	00h RW	L1 Device Slot (L1DS): Note: This register is sticky. System software sets this field to indicate the ID of the Device Slot associated with the device directly attached to the Root Hub port. A value of 0 indicates no device is present. The xHC uses this field to lookup information necessary to generate the LPM Token packet. Power Well: SUS
7:4	0h RW	Best Effort Service Latency (HIRD): Note: This register is sticky. System software sets this field to indicate to the recipient device how long the xHC will drive resume if it (the xHC) initiates an exit from L1. For more information about <i>BESL</i> value encoding, refer to the xHCI for USB specification. Note that the <i>BESL</i> field is used by both software and hardware controlled LPM. Refer to the xHCI for USB specification for more information on <i>BESL</i> use and how <i>DBESL</i> may be used to establish an initial value for <i>BESL</i> . Power Well: SUS
3	0b RW	Remote Wake Enable (RWE): Note: This register is sticky. System software sets this flag to enable or disable the device for remote wake from L1. The value of this flag shall temporarily (while in L1) override the current setting of the Remote Wake feature set by the standard Set/ClearFeature() commands defined in Universal Serial Bus Specification, revision 2.0, Chapter 9. Power Well: SUS

There are 9 PORTHLP registers at offsets 48Ch, 49Ch, 4ACh, 4BCh, 4CCh, 4DCh, 4ECh, 4FCh and 50Ch. This register is reset only by platform hardware during cold reset or in response to a Host Controller Reset (HCRST). The field definitions depend on the protocol supported. For USB3, this register is reserved and shall be treated by software as RsvdP. For USB2, the definition is given below. Fields contain parameters necessary for xHC to automatically generate an LPM Token to the downstream device.

Type: Memory Mapped I/O Register
(Size: 32 bits)

MBAR Type: PCI Configuration Register (Size: 64 bits)

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:14	00000h RO	RESERVED (RSVD): Reserved. Power Well: Core
13:10	0h RW	Host Initiated Resume Duration-Deep (HIRDD): System software sets this field to indicate to the recipient device how long the xHC will drive resume upon exit from L1. The HIRDD value is encoded as follows: • 0h = 50 us (default) • 1h = 125 us • 2h = 200 us • ... • Fh = 1.175ms The value of 0h is interpreted as 50 us. Each incrementing value adds 75 us to the previous value. Power Well: SUS

Bit Range	Default & Access	Field Name (ID): Description
9:2	00h RW	L1 Timeout (L1TO): Timeout value for L1 inactivity timer. This field shall be set to 00h by assertion of PR to '1'. Following are permissible values: 00h: 128 us (default) 01h: 256 us. ... FFh: 65,280us Note: This register is sticky. Power Well: SUS
1:0	0h RW	Host Initiated Resume Duration Mode (HIRDM): Indicates which HIRD value should be used. The following are permissible values: 0 = Initiate L1 using HIRD only time out (default) 1 = Initiate HIRDDon timeout. If rejected by device, initiate L1 using HIRD 2,3 = Reserved Note: This register is sticky. Power Well: SUS

31:6	0000000h RW	Event Ring Segment Table Base Address Register (ERSTBA_LO): This field defines the low order bits of the start address of the Event Ring Segment Table. Writing this register sets the Event Ring State Machine:EREP Advancement to the Start state. Refer to the xHCI for USB specification for more information. This field shall not be modified if HCHalted (HCH) = 0. Power Well: Core
5:0	00h RO	Rsvd1: Reserved. Power Well: Core

18.7.93 Event Ring Segment Table Base Address High 8 (ERSTBA_HI8)—Offset 2114h

The *Event Ring Segment Table Base Address Register* identifies the start address of the Event Ring Segment Table. There are 8 ERSTBA_HIx registers, with x = 1, 2, ... 8.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 2114h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31	0b RW	Reset USB3 AUX/Main PD Logic (RST_U3_AM_PDL): A reset that is designed to reset all USB3 port AUX + Main power domain logic. This is a debug function. It is called cold reset. A write of 1 to this register will issue a cold reset to USB3 ports. Power Well: SUS
30	0b RW	RESERVED (RSVD): Reserved. Power Well: SUS
29	0b RW	Enable PCIe PIPE Reset As PCIe PHY Reset (EN_PPIPE_PPHY_RST): This bit set to 1 selects the PCIe PIPE reset as a PCIe PHY power on reset. 0 selects the AUX powerup reset as a PCIe PHY powerup reset. Power Well: SUS
28	0b RW	Ensure PIPE Powerdown On PERST# (EN_PPWRDN_PERST): This bit ensures any PERST# being asserted will cause PIPE powerdown state transition to P1. Power Well: SUS
27	0b RW	Disable PERST# Main RST (DIS_PERST_MRST): There is a feature where we only allow PERST# to be treated as a main powerdown reset when it is asserted during the state that is not in D3. This bit disables this feature when it is set to 1. If this bit is set to 1, it means that any PERST# will be treated as a main power domain reset regardless of its Dstate. Power Well: SUS
26	0b RW	Disable PCIe PERST# Host Controller (DIS_PERST_HC): There is a feature where we can disable PCIe PERST# from reset the host controller until power management control module has done its clock switching. This is for a case where PM entered L23 and immediately PERST# asserted. This bit is designed to enable this feature when set to 1. Power Well: SUS
25	0b RW	Enable Fast Simulation Reset Mode (EN_FAST_RST): Enable a fast simulation mode for reset function. This is a feature for GLS Power Well: SUS
24	1b RW	Prevent USB3 Link Down Reset (PREV_U3_LDRST): When set to 1, prevent a reset being generated due to the USB3 port link down condition. Power Well: SUS
23	0b RW	Ignore Main Power Up Reset (IGN_MPU_RST): When set to 1, ignore the main power up reset for USB3 PIPE PHY reset. Power Well: SUS

Bit Range	Default & Access	Field Name (ID): Description
22	1b RW	RESERVED (RSVD_1): Reserved. Power Well: SUS
21	0b RW	Ignore HC Reset USB2 (IGN_HC_RST_U2): When set to '1', ignore HC reset to reset the USB2 Port logic. Power Well: SUS
20	1b RW	Ignore HC Reset USB PHY (IGN_HC_RST_UP_POR): When set to '1', ignore HC reset to the USB PHY power-on reset. Power Well: SUS
19	1b RW	Enable PCIe Link-Down Reset (EN_PLD_RST): Enable a reset due to a PCIe link-down condition. The PCIe link down condition will cause a HC reset linked. If this bit is set 1, the PCIe link down condition will only reset the PCIe core. Power Well: SUS
18	1b RW	Enable EEPROM Reload On Power Up (EN_EEP_REL_PU): When set to '1', enable EEPROM reload on every main power-up. Power Well: SUS
17	1b RW	Ignore HC Reset PCIe PHY PIPE (IGN_HC_RST_PPP): When set to '1', ignore HC reset to the PCIe PHY PIPE reset. Power Well: SUS
16	1b RW	Ignore LTSSM Reset USB PHY PIPE (IGN_LRST_UPP): When set to '1', ignore the LTSSM of USB link state transition caused reset to USB PHY PIPE reset. Power Well: SUS
15	1b RW	Ignore Warm Reset USB PHY Power (IGN_WR_UPP): When set to '1', ignore warm reset the USB PHY power on reset. Power Well: SUS
14	1b RW	Allow Core PCIe Link Down Reset (ALL_CPLD_RST): When set to '1', allow PCIe link down to cause a reset to the rest of the core. Power Well: SUS
13	0b RW	Ignore Hot Reset USB3 (IGN_HR_U3): When set to '1', ignore hot reset to the USB3 port logic. Power Well: SUS
12	0b RW	Ignore Warm Reset USB3 (IGN_WR_U3): When set to '1', ignore warm reset to the USB3 port logic Power Well: SUS
11	0b RW	Ignore Main Power Up Reset USB3 (IGN_MPU_RST_U3): When set to '1', ignore main power up reset to USB3 port logic. Power Well: SUS
10	0b RW	Ignore Main Power Up Reset USB2 (IGN_MPU_RST_U2): When set to '1', ignore main power up reset to USB2 port logic. Power Well: SUS

Bit Range	Default & Access	Field Name (ID): Description
9	0b RW	Ignore Main Power Up Reset PCIe Core (IGN_MPU_RST_PC): When set to '1', ignore main power up reset to PCIe core. Power Well: SUS
8	0b RW	Ignore Main Power Up Reset PCIe PHY (IGN_MPU_RST_PP): When set to '1', ignore main power up reset to PCIe PHY. Power Well: SUS
7	1b RW	Ignore HC Reset USB PHY (IGN_HC_RST_UP): When set to '1', ignore HC reset to the USB PHY. Power Well: SUS
6	1b RW	Ignore Warm Reset USB PHY (IGN_WRST_UP): When set to '1', ignore warm reset to the USB PHY. Power Well: SUS
5	1b RW	Enable HC Reset Per Port Isolation (EN_HC_RST_PPI): Enables the HC reset or per port reset isolation function. Power Well: Core
4	1b RW	Allow Power Off Power Domain Reset (ALL_PO_PDRST): When set to '1', allow main power off condition to trigger a main power domain reset. Power Well: SUS
3	0b RW	Ignore Wait For PERST# During Power Shut Down (IGN_PERST_PSD): When set to '1', ignore waiting for PERST# deassertion during main power shut down. Power Well: SUS
2	0b RW	Ignore Fundamental Reset During AUX Power Up (IGN_FRST_AUX_PU): If this bit is set and a fundamental reset is asserted during AUX power up, then PERST# shall be ignored and a timeout will be allowed to deassert fundamental reset instead. Power Well: SUS
1:0	0h RW	Trigger Fundamental Reset (TRIG_FRST): Writing to bit(1:0) to value of 2'b11 will cause a fundamental reset Power Well: SUS

18.7.151 Super Speed Bandwidth Overload (HOST_BW_OV_SS_REG)—Offset 80C4h

Access Method

	ETH	BPSAW	BPSMID							

Bit Range	Default & Access	Field Name (ID): Description
31:24	0ah RW	Engine Idle Hysteresis (EIH): This register controls the min. idle span that has to be observed from the engine idle indicators before the power state flags (xhc*_idle) will indicate a 1. Power Well: Core
23:12	019h RW	Backbone PLL Shutdown Advance Wake (BPSAW): This register controls the time before the next scheduled transaction where the Backbone PLL request will assert. - Register Format: - Bits [11:7] # of 125us uframes - Bits [6:0] # of microseconds (0-124) Power Well: Core
11:0	132h RW	Backbone PLL Shutdown Min. Idle Duration (BPSMID): The sum of this register plus the Backbone PLL Shutdown Advance Wake form to a Total Idle time. When the next scheduled periodic transaction is after present time + Total Idle, the Backbone PLL request will de-assert, allowing the PLL to shutdown. Register Format: - Bits [11:7] # of 125us uframes - Bits [6:0] # of microseconds (0-124) Power Well: Core

18.7.173 Power Scheduler Control-2 (PWR_SCHED_CTRL2)—Offset 8144h

These bit enable by EP type those EPs classes that are considered for determining next periodic active interval for pre-wake of the periodic_active signal. EP classes that are disabled may never be observed in setting of the periodic_active signal.

Bit Range	Default & Access	Field Name (ID): Description
0	1b RW	SS ISO-IN Alarm (SS_ISO_IN_ALARM): Reserved. Power Well: Core

18.7.174 Latency Tolerance Control 0 (HOST_IF_LAT_TOL_CTRL_REG0)—Offset 8150h

The Latency Tolerance Control Register is used by SW to control which BELT is returned when this register is read. SW shall write to this register to program a Slot-ID, Port-ID and BELT Select to determine which BELT is selected. When this register is read the selected BELT is returned.

Access Method

Type: Memory Mapped I/O Register

31:28	0h RW	RESERVED0 (RSVD0): Reserved. Power Well: SUS
27:25	0h RW	RESERVED (RSVD): Reserved. Power Well: SUS

Bit Range	Default & Access	Field Name (ID): Description
24	1b RW	Enable L1 exit notification to SNPS PCIe core (EN_L1_EXIT_NOTIF_PCIE): This bit enables a L1 exit notification to SNPS PCIe core. There is a case where USB ports have waked up and AUX PM module has started the wakeup process. The AUX PM control state got into a wait for P0 state because it needs to wait until PCIe core to signal powerdown state change. Due to the fact that the core is in D3Hot, there is no run_stop bit set such that no internal interrupt will be fired. This causes the LTSSM of PCIe stayed in L1 even though AUX PM has known that it needs an L1 exit. This bit works together with bit21 of this register. 1 = enables this feature 0 = disables this feature. Power Well: SUS
23	0b RW	DISABLE PLC ON DISCONNECT (DIS_PLC_ON_DISCONNECT): 1 = do not assert PLC for disconnection 0 = assert PLC for disconnection Power Well: SUS
22	0b RW	TREAT_IDLE_AS_TS2_IN_LTSSM_WAIT_4_TS2: This bit enables a feature in PCIe core LTSSM to treat IDLE received as TS2 when LTSSM is in wait for TS2 receive state. This is a function requested from PHY where it is possible to not able to receive TS2 without error. 1 = treat Logic IDLE as TS2 received when in some PCIe LTSSM state. 0 = disable this feature. Power Well: SUS
21	1b RW	Disable p2 overwrite due to the D3HOT where PCIe core enters the L1 (DIS_P2_OVERWRITE_DUE2_D3HOT): We added a feature where if PCIe core LTSSM enters L1 due to the D3hot, the aux PM control will not start a P2 overwrite function in anticipating for the next L23 enter. 1 = disables p2 overwrite due to the D3HOT where PCIe core enters the L1. 0 = enables P2 overwrite even if we are in D3Hot. Power Well: SUS
20	1b RW	Enable the port to enter U3 automatically when in U1/U2 (ENABLE_AUTO_U3_ENTRY_FROM_U2_U3): 1 = enables the port to enter U3 automatically when in U1/U2 0 = disables the port to enter U3 automatically when in U1/U2 Power Well: SUS
19	1b RW	No linkdown reset is issued during low power state (DIS_LINKDOWN_RST_DURING_LOW_POWER): No linkdown reset is issued during low power state. Power Well: SUS
18	0b RW	EN_EXIT_DEEP_SLEEP_IF_PCIE_IN_P0: This bit enables a feature in AUX PM module where if PCIe core LTSSM is in P0 for a duration of time, we will exit the deep sleep state. This is for failure control in case. 1 = enable this feature 0 = disable this feature Power Well: SUS
17	0b RW	U2_EXIT_LFPS_TIMER_VALUE: This bit selects U2 exit LFPS timer value. 0 = 320ns 400ns in 25MHz domain 1 = 240ns 320ns in 25MHz domain Power Well: SUS

Bit Range	Default & Access	Field Name (ID): Description
16	1b RW	EN_EXIT_DEEP_SLEEP_ON_USB_PORT_WAKEUP: This bit enables a function that AUX PM module exits from the deep sleep state due to the USB ports wakeup level signal. We have added this feature where USB ports will generated a wakeup level signal to wakeup the AUX PM module if it is in deep sleep state and this level signal will be cleared if the change bits are updated by software. 1 = enables this function 0 = disables this function which means that a wakeup pulse generated from each USB PortSC event will wake up the AUX PM module from deep sleep if the D3 state is programmed. Power Well: SUS
15:14	0h RW	P3_ENTRY_TIMEOUT: This field defines the timeout value to enter P3 mode in U2. 00 = 7us 8us 01 = 511us 512us 10 = disables the timer (0us) 11 = disables the timer (0us) Power Well: SUS
13	0b RW	Enable U2 P3 Mode (EN_U2_P3): 0 = Disable U2 P3 mode 1 = Enable U2 P3 mode Power Well: SUS
12:11	0h RW	Fine Debug Mode Select (FINE_DM_SEL): Reserved. Power Well: SUS
10	0b RW	Enable Low Power State Based Core Clock Gating (EN_LP_CORE_CG): When set to '1', enable core clock gating based on low power state entered Power Well: SUS
9	1b RW	Disable USB3 Port Status Changed Event (DIS_U3_PORT_SCE): 0 = Enable USB3 port status change event generation if any change bit is not cleared 1 = Disable USB3 port status change event generation if any change bit is not cleared Bit 12 default 0 Power Well: SUS
8:4	00h RW	Debug Mode Select Register (DEB_MODE_SEL): Reserved. Power Well: SUS
3	0b RW	Enable Auto Wakeup Non-IDLE (EN_AWAK_NIDLE): When set to 1, enables the auto wakeup function when engine has identified non IDLE condition. Power Well: SUS
2	1b RW	Enable PM Control P1 Exit P2 (EN_PMC_P1_EXIT_P2): When set to 1, enables the PM control module to transition to P1 instead of P0 upon exit from P2. Power Well: SUS
1	1b RW	Enable PCIe PIPE CLK Isolation (EN_PP_CLK_ISOL): When set to 1, enables the PCIe PIPE CLK to be isolated when main power is removed. Power Well: SUS

Bit Range	Default & Access	Field Name (ID): Description
0	0b RW	Enable P2 Overwrite P1 Allowed Detect (EN_P2OVRP1_ADET): When set to 1, enables a function that can detect whether or not enable P2 overwrite P1 function. The condition to get to P2 overwrite is when engine is in idle conditions. This means that there is no ISO EP pending. Power Well: SUS

31:20	000h RO	Reserved (RSVD): Reserved.
19	0b RW	USB3 Partition Engine/Link trunk gating Enable (PARUSB3_ENG_GEN): When set to 1 enables gating of the SOSC trunk to the XHCI engine and link in the PARUSB3 partition. Power Well: SUS
18	0b RW	USB3 Partition Frame Timer trunk gating Enable (PARUSB3_LINK_GEN): When set to 1 enables gating of the SOSC trunk to the Frame timer in the PARUSB3 partition. Power Well: SUS
17	0b RW	USB2 link partition clock gating enable (PARUSB2_CLK_GEN): When set to 1 enables gating of the SOSC trunk to the USB2 link and Phy logic in the PARUSB2 partition. Power Well: SUS
16	0b RW	USB2/USHIP 12.5 MHz partition clock gating enable (USHIP_PCGEN): When set to 1 enables gating of the 12.5 MHz SOSC trunk to the USB2 and USHIP logic in the PARUSB2 partition. Power Well: SUS
15	0b RO	Reserved1 (RSVD1): Reserved
14	0b RW	USB3 Port Aux/Core clock gating enable (USB3_AC_CGE): When set, allows the aux_cclk clock into the USB3 port to be gated when conditions are met. Usage of this bit is further qualified with xHC Dynamic Clock Gating Disable fuse. If the fuse disables dynamic clock gating, Aux clock gating will not be enabled either. This bit always returns the value that was written to it, irrespective of the setting of xHC Dynamic Clock Gating Disable fuse. Power Well: SUS

Bit Range	Default & Access	Field Name (ID): Description
13:12	0h RW	Rx Detect Timer when port Aux Clock is Gated (RX_DT_ACG): This field defines the value of the timer used to perform Rx Detect when port Aux Clock has been gated. 0x0 = 100ms 0x1 = 12ms - Others = Reserved Note: This timer shall use the Fast Training Timer Tick (about 1us tick) for simulation purposes. For Fast Training mode, the above timeouts will become about 11us and about 100us, +/- implementation uncertainty, respectively. Power Well: SUS
11:8	4h RW	U2 Residency Before ModPHY Clock Gating (U2R_BM_CG): Before gating ModPHY Aux clock, Host Controller shall wait for this time in U2. This time is meant to ensure that the attached device has entered U2 as well. 0x0 = 1us 0x1 = 128us 0x2 = 256us 0x3 = 512us 0x4 = 640us 0x5 = 768us 0x6 = 896us 0x7 = 1024us - Others = Reserved Note: This counter shall start counting once pipe has entered PS3 state in response to link in U2. Power Well: SUS
7	0h RW	Frame Timer Clock Gating Ports in U2 Enable (FTCGPU2E): This bit, when set, allows Host Controller to gate the clock to the Frame Timer when ports are in U2. Power Well: SUS
6	0b RW	USB2 port clock throttle enable (USB2_PC_TE): When set, allows the Aux clock into the USB2 ports to be throttled when conditions allow. Power Well: SUS
5	0b RW	XHCI Engine Aux clock gating enable (XHCI_AC_GE): When set, allows the aux clock into the XHCI engine to be gated when idle. Usage of this bit is further qualified with xHC Dynamic Clock Gating Disable fuse. If the fuse disables dynamic clock gating, Aux clock gating will not be enabled either. This bit always returns the value that was written to it irrespective of the setting of xHC Dynamic Clock Gating Disable fuse. Power Well: SUS
4	0b RW	XHCI Aux PM block clock gating enable (XHCI_APMB_CGE): When set, allows the aux clock into the Aux PM block to be gated when idle. Usage of this bit is further qualified with xHC Dynamic Clock Gating Disable fuse. If the fuse disables dynamic clock gating, Aux clock gating will not be enabled either. This bit always returns the value that was written to it irrespective of the setting of xHC Dynamic Clock Gating Disable fuse. Power Well: SUS
3	0b RW	USB3 Aux Clock Trunk Gating Enable (USB3_AC_TGE): When set, allows Aux Clock Trunk feeding to USB3.0 ports to be gated when port Aux clock is gated at all USB3.0 ports and all USB3.0 modPHY instances. Usage of this bit is further qualified with xHC Dynamic Clock Gating Disable fuse. If the fuse disables dynamic clock gating, Aux clock gating will not be enabled either. This bit always returns the value that was written to it irrespective of the setting of xHC Dynamic Clock Gating Disable fuse. Power Well: SUS

18.7.179 USB LPM Parameters (USB_LPM_PARAM)—Offset 8170h

Bit Range	Default & Access	Field Name (ID): Description
2	0b RW	USB3 Port Aux/Port clock gating enable (USB3_AP_CGE): When set, allows the aux_pclk clock into the USB3 port to be gated when conditions are met. Usage of this bit is further qualified with xHC Dynamic Clock Gating Disable fuse. If the fuse disables dynamic clock gating, Aux clock gating will not be enabled either. This bit always returns the value that was written to it irrespective of the setting of xHC Dynamic Clock Gating Disable fuse. Power Well: SUS
1	0b RW	ModPHY port Aux clock gating enable in U2 (MPP_AC_GEU2): When set, allows the aux clock into the ModPhy to be gated when Link is in U2 and pipe has been in PS3 for at least the time defined by U2 Residency Before ModPHY Clock Gating field. Usage of this bit is further qualified with xHC Dynamic Clock Gating Disable fuse. If the fuse disables dynamic clock gating, Aux clock gating will not be enabled either. This bit always returns the value that was written to it irrespective of the setting of xHC Dynamic Clock Gating Disable fuse. Power Well: SUS
0	0b RW	ModPHY port Aux clock gating enable in Disconnected, U3 or Disabled (MPP_AC_GE_DDU3): When set, allows the aux clock into the ModPHY to be gated when Link is in Disconnected, U3 or Disabled state. Usage of this bit is further qualified with xHC Dynamic Clock Gating Disable fuse. If the fuse disables dynamic clock gating, Aux clock gating will not be enabled either. This bit always returns the value that was written to it irrespective of the setting of xHC Dynamic Clock Gating Disable fuse. Power Well: SUS

18.7.193 Debug Capability Event Ring Segment Table Base Address Register (DCERSTBA)—Offset 8490h

The *Debug Capability Event Ring Segment Table Base Address Register* identifies the start address of the Debug Capability Event Ring Segment Table.

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

Offset: [MBAR] + 8490h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Field Name (ID): Description
63:4	000000000 000000h RW	Event Ring Segment Table Base Address Register (ERSTBAR): This field defines the high order bits of the start address of the Debug Capability Event Ring Segment Table. Software shall initialize this register before setting the <i>Debug Capability Enable</i> field in the DCCTRL register to 1. Power Well: Core
3:0	0h RW	Reserved (RSVD): Reserved. Power Well: Core

18.7.194 Debug Capability Event Ring Dequeue Pointer Register (DCERDP)—Offset 8498h

The *Debug Capability Event Ring Dequeue Pointer Register* is written by software to define the Debug Capability Event Ring Dequeue Pointer location to the xHC. Software updates this pointer when it has finished the evaluation of an Event(s) on the Debug Capability Event Ring.

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

Offset: [MBAR] + 8498h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Field Name (ID): Description
63:4	00000000 000000h RW	Dequeue Pointer (DQP): This field defines the high order bits of the 64-bit address of the current Debug Capability Event Ring Dequeue Pointer. Software shall initialize this register before setting the <i>Debug Capability Enable</i> field in the DCCTRL register to '1'. Power Well: Core
3	0b RW	Reserved (RSVD): Reserved. Power Well: Core
2:0	0h RW	Dequeue ERST Segment Index (DESI): This field may be used by the xHC to accelerate checking the Event Ring full condition. This field is written with the low order 3 bits of the offset of the ERST entry which defines the Event Ring segment that the Event Ring Dequeue Pointer resides in. Power Well: Core

18.7.195 Debug Capability Control Register (DCCTRL)—Offset 84A0h

The *Debug Capability Control Register* is used to manage the Debug Capability.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 84A0h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
DCE	DADDR			DMBS	RSVD			DRC HIT HOT LSE DCR

Bit Range	Default & Access	Field Name (ID): Description
31	0b RW	Debug Capability Enable (DCE): Setting this bit to a 1 enables xHCI USB Debug Capability operation. This bit is a 0 if the USB Debug Capability is disabled. Clearing this bit releases the Root Hub port assigned to the Debug Capability, and terminates any Debug Capability Transfer or Event Ring activity. Power Well: Core
30:24	00h RO	Device Address (DADDR): This field reports the USB device address assigned to the Debug Device during the enumeration process. This field is valid when the <i>DbC Run</i> bit is 1. Power Well: Core
23:16	00h RO	Debug Max Burst Size (DMBS): This field identifies the maximum burst size supported by the bulk endpoints of this DbC implementation. LPT-LP USB Debug Device does not support bursting. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
15:5	000h RO	Reserved (RSVD): Reserved. Power Well: Core
4	0b RW/C	DbC Run Change (DRC): This bit shall be set to '1' when DCR bit is cleared to '0', i.e. by any DbC Port State transition that exits the DbC-Configured state. While this bit is 1 the <i>Debug Capability Doorbell Register</i> (DCDB) is disabled. Software shall clear this bit to re-enable the DCDB. Power Well: Core
3	0b RW/S	Halt IN TR (HIT): While this bit is 1 the Debug Capability shall generate STALL TPs for all OUT DPs received for the IN TR. The Debug Capability shall clear this bit when a ClearFeature(ENDPOINT_HALT) request is received for the endpoint. This field is valid only when the Debug Capability is in Run Mode (DCR = 1). When not in Run Mode, this field shall return 0 when read, and writes will have no effect. Refer to the xHCI USB specification for more information. Power Well: Core
2	0b RW/S	Halt OUT TR (HOT): While this bit is 1 the Debug Capability shall generate STALL TPs for all IN TPs received for the OUT TR. The Debug Capability shall clear this bit when a ClearFeature(ENDPOINT_HALT) request is received for the endpoint. This field is valid only when the Debug Capability is in Run Mode (DCR = 1). When not in Run Mode, this field shall return 0 when read, and writes will have no effect. Refer to the xHCI USB specification for more information. Power Well: Core
1	0b RW	Link Status Event Enable (LSE): Setting this bit to a 1 enables the Debug Capability to generate Port Status Change Events due to the <i>Port Link Status Change</i> bit transitioning from a 0 to a 1. Refer to the xHCI USB specification for more information. Power Well: Core
0	0b RO	DbC Run (DCR): When 0, Debug Device is not in the Configured state. When 1, Debug Device is in the Configured state and bulk Data pipe transactions are accepted by Debug Capability and routed to the IN and OUT Transfer Rings. A 0 to 1 transition of the <i>Port Reset</i> (DCPORTSC:PR) bit will clear this bit to 0. Power Well: Core

18.7.196 Debug Capability Status Register (DCST)—Offset 84A4h

The *Debug Capability Status Register* reports capability related status information to software.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 84A4h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
DPNUM				RSVD				ERNE

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Debug Port Number (DPNUM): This field provides the ID of the Root Hub port that the Debug Capability has been automatically attached to. The value is '0' when the Debug Capability is not attached to a Root Hub port. Power Well: Core
23:1	000000h RO	Reserved (RSVD): Reserved. Power Well: Core
0	0b RO	Event Ring Not Empty (ERNE): When '1', this field indicates that the Debug Capability Event Ring has a Transfer Event on it. It is automatically cleared to '0' by the xHC when the Debug Capability Event Ring is empty, i.e. the Debug Capability Enqueue Pointer is equal to the <i>Debug Capability Event Ring Dequeue Pointer</i> register. Power Well: Core

18.7.197 Debug Capability Port Status and Control Register (DCPORTSC)—Offset 84A8h

The fields of the *Debug Capability PORTSC Register* are defined below and provide information about the state of the Root Hub port that is assigned to the Debug Capability. Note that the fields in this register function differently than those in a normal *Port Status and Control Register* (described in section 5.4.8) because the Root Hub port assigned to the Debug Capability is acting as an Upstream Facing Port, not a Downstream Facing Port.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 84A8h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 00000000h

31				28				24				20				16				12				8				4				0													
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0													
RSVD								CEC		PLC		PRC		RSVD_1				CSC		RSVD_2				PSPD				RSVD_3				PLS				PR		RSVD_4				PED		CCS	

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Reserved (RSVD): Reserved. Power Well: Core
23	0b RW/C	Port Config Error Change (CEC): This flag indicates that the port failed to configure its link partner. 0 = No change 1 = Port Config Error detected Software shall clear this bit by writing a '1' to it. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
22	0b RW/C	Port Link Status Change (PLC): This flag is set to '1' due to the following PLS transitions: - U0 -> U3 = Suspend signaling detected from Debug Host - U3 -> U0 = Resume complete - Polling -> Disabled = Training Error - Ux or Recovery -> Inactive = Error Software shall clear this bit by writing a '1' to it. This field is '0' if DCE is '0'. Power Well: Core
21	0b RW/C	Port Reset Change (PRC): This bit is set when reset processing on this port is complete (i.e. a '1' to '0' transition of PR). '0' = No change '1' = Reset complete Software shall clear this bit by writing a '1' to it. This field is '0' if DCE is '0'. Power Well: Core
20:18	0h RO	Reserved (RSVD_1): Reserved. Power Well: Core
17	0b RW/C	Connect Status Change (CSC): an already-set bit (i.e., the bit will remain '1'). Software shall clear this bit by writing a '1' to it. This field is '0' if DCE is '0'. Power Well: Core
16:14	0h RO	Reserved (RSVD_2): Reserved. Power Well: Core
13:10	0h RO	Port Speed (PSPD): This field identifies the speed of the port. This field is only relevant when a Debug Host is attached (CCS = '1') in all other cases, this field shall indicate Undefined Speed. 0 Undefined Speed 1-15 Protocol Speed ID (PSI) Refer to the xHCI for USB specification for the definition of PSIs. Note: The Debug Capability does not support LS, FS, or HS operation. Power Well: Core
9	0b RO	Reserved (RSVD_3): Reserved. Power Well: Core
8:5	0h RO	Port Link State (PLS): This field reflects its current link state. This field is only relevant when a Debug Host is attached (Debug Port Number) '0'). 0 = Link is in the U0 State 1 = Link is in the U1 State 2 = Link is in the U2 State 3 = Link is in the U3 State (Device Suspended) 4 = Link is in the Disabled State 5 = Link is in the RxDetect State 6 = Link is in the Inactive State 7 = Link is in the Polling State 8 = Link is in the Recovery State 9 = Link is in the Hot Reset State 15:10 = Reserved Note: Transitions between different states are not reflected until the transition is complete. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
4	0b RO	Port Reset (PR): '1' = Port is in Reset '0' = Port is not in Reset This bit is set to '1' when the bus reset sequence as defined in the USB Specification is detected on the Root Hub port assigned to the Debug capability. It is cleared when the bus reset sequence is completed by the Debug Host, and the DbC shall transition to the USB Default state. A '0' to '1' transition of this bit shall clear DCPORTSC PED ('0'). This field is '0' if DCE or CCS are '0'. Power Well: Core
3:2	0h RO	Reserved (RSVD_4): Reserved. Power Well: Core
1	0b RW	Port Enabled/Disabled (PED): '1' = Enabled. '0' = Disabled. This flag shall be set to '1' by a '0' to '1' transition of CCS or a '1' to '0' transition of the PR. When PED transitions from '1' to '0' due to the assertion of PR, the port's link shall transition to the Rx.Detect state. This flag may be used by software to enable or disable the operation of the Root Hub port assigned to the Debug Capability. The Debug Capability Root Hub port operation may be disabled by a fault condition (disconnect event or other fault condition, e.g. a LTSSM Polling substate timeout, tPortConfiguration timeout error, etc.), the assertion of DCPORTSC PR, or by software. 0 = Debug Capability Root Hub port is disabled. 1 = Debug Capability Root Hub port is enabled. When the port is disabled (PED = '0') the port's link shall enter the SS.Disabled state and remain there until PED is reasserted ('1') or DCE is negated ('0'). Note that the Root Hub port is remains mapped to Debug Capability while PED = '0'. While PED = '0' the Debug Capability will appear to be disconnected to the Debug Host. Note: This bit is not affected by PORTSC PR bit transitions. This field is '0' if DCE or CCS are '0'. Power Well: Core
0	0b RO	Current Connect Status (CCS): '1' = A Root Hub port is connected to a Debug Host and assigned to the Debug Capability. '0' = No Debug Host is present. This value reflects the current state of the port, and may not correspond to the value reported by the <i>Connect Status Change</i> (CSC) field in the <i>Port Status Change Event</i> that was generated by a '0' to '1' transition of this bit. This flag is '0' if Debug Capability Enable (DCE) is '0'. Power Well: Core

18.7.198 Debug Capability Context Pointer Register (DCCP)—Offset 84B0h

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

Offset: [MBAR] + 84B0h

MBAR Type: PCI Configuration Register (Size: 64 bits)

MBAR Reference: [B:0, D:20, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Field Name (ID): Description
63:4	00000000 000000h RW	Debug Capability Context Pointer Register (DCCPR): This field defines the high order bits of the start address of the Debug Capability Context data structure associated with the Debug Capability. Software shall initialize this register before setting the Debug Capability Enable bit in the Debug Capability Control Register to '1'. Power Well: Core
3:0	0h RO	Reserved (RSVD): Reserved. Power Well: Core

18.7.199 Debug Capability Device Descriptor Info Register 1 (DCDDI1)—Offset 84B8h

The *Debug Capability Device Descriptor Register 1* identifies the Device Protocol and Vendor ID values that shall be reported by DbC in its Device Descriptor when it is enumerated by a Debug Host. Refer to section 9.6.1, Table 9-8 in the USB3 spec. This register shall be initialized before enabling the DbC (DCE = '1').

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 84B8h

MBAR Type: PCI Configuration Register (Size: 64 bits)

F8–FBh	4	"Manufacturer's ID (MANID)—Offset F8h" on page 2374	00000F86h

Bit Range	Default & Access	Field Name (ID): Description
29	0b RWC	Received Master-Abort Status (RMA_0): This bit is set when USB2, as a master, receives a master-abort status on a memory access. This is treated as a Host Error and halts the DMA engines. This event can optionally generate an SERR# by setting the SERR# Enable bit and the SERR on Aborts Enable (bit 3, offset 84h). Software clears this bit by writing a '1' to this bit location. Power Well: Core
28	0b RWC	Received Target Abort Status (RTA_0): This bit is set when USB2, as a master, receives a target abort status on a memory access. This is treated as a Host Error and halts the DMA engines. This event can optionally generate an SERR# by setting the SERR# Enable bit and the SERR on Aborts Enable (bit 3, offset 84h). Software clears this bit by writing a '1' to this bit location. Power Well: Core
27	0b RO	Signaled Target-Abort Status (STA_0): This bit is used to indicate when the USB2 function responds to a cycle with a target abort. There is no reason for this to happen, so this bit will be hard-wired to '0'. Read-Only Power Well: Core
26:25	01b RO	DEVSEL# Timing Status (DEVT_0): This 2-bit field defines the timing for DEVSEL# assertion. Read-Only. Power Well: Core
24	0b RWC	Master Data Parity Error Detected (MDPED_0): This bit is set whenever a data parity error is detected on a USB2 read completion packet on the internal interface to the USB2 host controller and bit 6 of the Command register is set to 1. Software clears this bit by writing a '1' to this bit location. Power Well: Core
23	1b RO	Fast Back-to-Back Capable (FBCAP_0): Reserved as '1'. Power Well: Core
22	0b RO	User Definable Features (UDF_0): Reserved as '0' Power Well: Core
21	0b RO	66 Mhz Capable (CLKCAP_0): Reserved as '0' Power Well: Core
20	1b RO	Capabilities List (CAPLIST_0): Hardwired to '1' indicating that offset 34h contains a valid capabilities pointer. Power Well: Core
19	0b RO	Interrupt Status (INTRSTS_0): This read-only bit reflects the state of this function's interrupt at the input of the enable/disable logic. This bit is a 1 when the interrupt is asserted. This bit will be 0 when the interrupt is deasserted. The value reported in this bit is independent of the value in the Interrupt Enable bit. Power Well: Core
18:11	00000000b RO	Reserved (RSVD): Reserved.

Bit Range	Default & Access	Field Name (ID): Description
10	0b RW	Interrupt Disable (INTRDIS_0): When cleared to '0', the function is capable of generating interrupts. When '1', the function can not generate its interrupt to the interrupt controller. Note that the corresponding Interrupt Status bit is not affected by the interrupt enable. This bit defaults to '0'. This bit is added as part of the PCI 2.3 Specification. Power Well: Core
9	0b RO	Fast Back to Back Enable (FBE_0): Reserved as '0'. Power Well: Core
8	0b RW	SERR# Enable (SERREN_0): on a memory read completion (if SERR on Aborts Enable is also set) Detection of an address or command parity error and the Parity Error Response bit is setDetection of a data parity error (when the data is going to the EHC) and the Parity Error Response bit is set Power Well: Core
7	0b RO	Wait Cycle Control (WCC_0): Reserved as '0'. Power Well: Core
6	0b RW	Parity Error Response (PER_0): When set to 1, the USB2 Host Controller will check for correct parity (on its internal interface) and halt operation when bad parity is detected during the data phase as recommended by the EHCI specification. If it detects bad parity on the address or command phases when this bit is set to 1, the host controller does not take the cycle, halts the host controller (if currently not halted) and sets the host system error bit in the USBSTS register. Note that this applies to both requests and completions from the system interface. See section 9.19.2.4 for information regarding parity errors detected by the Prefetch DMA Engine. This bit must be set in order for the parity errors to generate SERR#. Power Well: Core
5	0b RO	VGA Palette Snoop (VGAPS_0): Reserved as '0' Power Well: Core
4	0b RO	Postable Memory Write Enable (PMWE_0): Reserved as '0' Power Well: Core
3	0b RO	Special Cycle Enable (SCE_0): Reserved as '0' Power Well: Core
2	0b RW	Bus Master Enable (BME_0): When set, bus mastering from EHCI is allowed, and will generate memory reads and writes for USB transfers. Notes on the EHC implementation: - Writes to change this bit occur immediately. Specifically, a write followed by a read will return the updated value. - When the BME bit is changed from 1 to 0, the EHC will cease accessing main memory within 2 microframes (250 usec). During this time, any number of reads and/or writes to memory may occur. - Clearing the BME bit shuts down the EHC DMA engines in the same manner that clearing the Run/Stop does. However, the schedule status bits and the HCHalted bit do not change based on the BME value. Power Well: Core
1	0b RW	Memory Space Enable (MSE_0): This bit controls access to the USB2 Memory Space registers. If this bit is set, accesses to the USB2 registers are enabled. The Base Address register for USB2 should be programmed before this bit is set. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
0	0b RO	I/O Space Enable (IOSE_0): Reserved as '0'. Power Well: Core

18.8.3 Revision ID and Programming Interface and Sub/Base Class Code (RID_PI_CC)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:29, F:0] + 8h

Default: 0C032000h

31	28	24	20	16	12	8	4	0
0	0	0	0	1	1	0	0	0
0	0	0	0	0	0	1	0	0
0	0	0	0	0	0	0	0	0
BCC_0				SCC_0				RID_0

Bit Range	Default & Access	Field Name (ID): Description
31:24	0Ch RO	Base Class Code (BCC_0): A value of 0Ch indicates that this is a Serial Bus controller. Power Well: Core
23:16	03h RO	Sub Class Code (SCC_0): A value of 03h indicates that this is a Universal Serial Bus Host Controller. Power Well: Core
15:8	20h RO	Programming Interface (PI_0): A value of 20h indicates that this USB2 Host Controller conforms to the EHCI specification. Power Well: Core
7:0	00h RO	Revision ID (RID_0): The value reported in this register indicates stepping of the host controller hardware. Power Well: Core

18.8.5 Memory Base Address (MBAR)—Offset 10h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:29, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
BA_0							RSVD	PFETCH_0
								TYPE_0
								RTE_0

Bit Range	Default & Access	Field Name (ID): Description
31:10	000000h RW	Base Address (BA_0): Bits (31:10) correspond to memory address signals (31:10), respectively. This gives 1 KB of relocatable memory space aligned to 1 KB boundaries. Power Well: Core
9:4	000000b RO	Reserved (RSVD): Reserved.
3	0b RO	Prefetchable (PFETCH_0): Read Only. This bit is hardwired to 0 indicating that this range should not be prefetched. Power Well: Core
2:1	00b RO	Type (TYPE_0): indicating that this range can be mapped anywhere within 32-bit address space. Power Well: Core
0	0b RO	Resource Type Indicator (RTE_0): Read Only. This bit is hardwired to 0 indicating that the base address field in this register maps to memory space Power Well: Core

Type: PCI Configuration Register
(Size: 32 bits)

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
USB2SSID_0				USB2SVID_0				

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/L	USB2 Subsystem ID (USB2SSID_0): BIOS sets the value in this register to identify the Subsystem ID. This register, in combination with the Subsystem Vendor ID register, enables the operating system to distinguish each subsystem from other(s). Writes to this register are enabled when the WRT_RDONLY bit (offset 80h, bit 0) is set to 1. Writes should be done as a single 16-bit cycle. Reset: none Power Well: Core
15:0	0000h RW/L	USB2 Subsystem Vendor ID (USB2SVID_0): This register, in combination with the USB2 Subsystem ID register, enables the operating system to distinguish each subsystem from the others. Writes to this register are enabled when the WRT_RDONLY bit (offset 80h, bit 0) is set to 1. Reset: none Power Well: Core

18.8.7 Capabilities Pointer and Reserved (CAP_PTR_RSVD)—Offset 34h

Type: PCI Configuration Register
(Size: 32 bits) **Offset:** [B:0, D:29, F:0] + 34h

31	28	24	20	16	12	8	4	0

18.8.8 Interrupt Line and Interrupt Pin and Reserved (ILINE IPIN RSVD)—Offset 3Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:29, F:0] + 3Ch

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RSVD				IPIN_0				ILINE_0

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Reserved (RSVD): Reserved.
15:8	00h RO	Interrupt Pin (IPIN_0): Bits 3:0 reflect the value programmed in the interrupt pin registers in chipset configuration space. Bits 7:4 are hardwired to 0000b. NOTE: As a single function device, only INTA# may be used while the other three interrupt lines have no meaning. (refer to PCI 3.0 spec section 2.2.6 Interrupt Pins) Power Well: Core
7:0	00h RW	Interrupt line (ILINE_0): This data is not used by the SOC. It is used as a scratchpad register to communicate to software the interrupt line that the interrupt pin is connected to. Reset: core well and D3-to-D0. Power Well: Core

18.8.9 PCI Power Management Capability ID and Next Item Pointer #1 and PM Capabilities (PM_CID_NEXT_CAP)—Offset 50h

PCI Power Management Capabilities ID Next Item Pointer #1 Power Management Capabilities

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:29, F:0] + 50h

Default: C9C35801h

31				28				24				20				16				12				8				4				0			
1	1	0	0	1	0	0	1	1	1	0	0	0	0	1	1	0	1	0	1	1	0	0	0	0	0	0	0	0	0	0	1				
RSVD				D2SUP_0		D1SUP_0		AUXCUR_0		DSI_0		RSVD		PMECLK_0		VERS_0		PM_NEXT_0				PM_CID_0													

Bit Range	Default & Access	Field Name (ID): Description
31:27	11001b RO	Reserved (RSVD): Reserved.
26	0b RO	D2_Support (D2SUP_0): The D2 state is not supported. Reset: core well, but not D3-to-D0. Power Well: Core
25	0b RO	D1_Support (D1SUP_0): The D1 state is not supported. Reset: core well, but not D3-to-D0. Power Well: Core
24:22	111b RW/L	Aux_Current (AUXCUR_0): The USB2 SIP EHC reports 375mA maximum Suspend well current required when in the D3cold state. This value can be written by BIOS when a more accurate value is known. Power Well: Core
21	0b RO	DSI (DSI_0): The Intel EHC reports 0, indicating that no device-specific initialization is required. Reset: core well, but not D3-to-D0. Power Well: Core
20	0b RO	Reserved (RSVD): Reserved.
19	0b RO	PME Clock (PMECLK_0): The Intel EHC reports 0, indicating that no PCI clock is required to generate PME#. Reset: core well, but not D3-to-D0. Power Well: Core
18:16	011b RW/L	Version (VERS_0): Version: The Intel EHC reports 011, indicating that it complies with Revision 1.21 of the PCI Power Management Specification. Note: As contingency plan, the bit can be reverted by BIOS to 010b to support PCI PM Revision 1.1, by manipulating the offset80h Access Control register's WRT_RDONLY bit. Power Well: Core
15:8	58h RW/L	Next Item Pointer #1 (PM_NEXT_0): This register defaults to 58h, which indicates that the next capability registers begin at configuration offset 58h. This register is writable when the WRT_RDONLY bit is set. This allows BIOS to effectively hide the Debug Port capability registers, if necessary. This register should only be written during system initialization before the plug-and-play software has enabled any master-initiated traffic. Values of 58h implies Debug Port and FLR capabilities visible 98h implies Debug Port invisible, next capability is FLR 00h implies that both Debug port and FLR capability are hidden Note that this value is never expected to be programmed. Reset: core well, but not D3-to-D0 Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
3	1b RO	No Soft Reset (NO_SOFT_RESET): A '0' indicates device does perform an internal reset upon D3hot to D0 transition via software control of the PowerState bits. Configuration Context is lost. Full re-initialization sequence is needed to return the device to D0 Initialized.(Default to '1') Note: As contingency plan, the bit can be reverted by BIOS to 0, by manipulating the offset80h Access Control register's WRT_RDONLY bit. Power Well: Resume
2	0b RO	Reserved (RSVD): Reserved.
1:0	00b RW	PowerState (PWRST_0): This 2-bit field is used both to determine the current power state of EHC function and to set a new power state. The definition of the field values are: 00b - D0 state 11b - D3hot state If software attempts to write a value of 10b or 01b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3hot state, the accesses to the EHC memory range must not be accepted; but the configuration space must still be accessible. When not in the D0 state, the generation of the interrupt output is blocked. Specifically, the PIRQ[H] is not asserted when not in the D0 state. When software changes this value from the D3hot state to the D0 state, an internal warm (soft) reset is generated, and software must re-initialize the function. Power Well: Resume

18.8.11 Debug Port Capability ID and Next Item Pointer #2 and Debug Port Base Offset (DP_CID_NEXT_BASE)—Offset 58h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:29, F:0] + 58h

Default: 20A0980Ah

0	0	0	0	0	0	0	0	0
HCIVERSION_B0_0				RSVD				CAPLENGTH_0

October 2018
Document Number: 538136, Rev. 4.3

Bit Range	Default & Access	Field Name (ID): Description
15:12	0h RO	Number of Companion Controllers (N_CC_0): This field indicates the number of companion controllers associated with this USB 2.0 host controller. A zero in this field indicates there are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports. A value larger than one in this field indicates there are companion USB 1.1 host controller(s). Port-ownership hand-offs are supported. High, Full- and Low-speed devices are supported on the host controller root ports. There are no companion controllers. This field is set to '0' as Read-Only bit. Power Well: Core
11:8	0h RO	Number of Ports per Companion Controller (N_PCC_0): This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software. Read-Only. This register is only reset by the resume power well going low. It is not reset by a D3-to-D0 state transition or HCRESET (Host Controller Reset) Power Well: Core
7	0b RO	Port Routing Rules (PRR_0): This field indicates the method used by this implementation for how all ports are mapped to companion controllers. This is hardwired to 0, indicating that the first N_PCC (=2) ports are routed to the lowest numbered function companion host controller, the next N_PCC ports are routed to the next lowest function companion controller, and so on Power Well: Resume
6:5	00b RO	Reserved (RSVD): Reserved.
4	0b RO	Reserved (RSVD): Reserved.
3:0	8h RW	N_PORTS (NPORTS_0): This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register Space. Valid values are in the range of 1H to FH. The default value for the EHCI controller indicates 8 ports. BIOS may overwrite the default value to properly describe the board or chip SKU . (please refer to RMH Configuration Details in section 1.23.2). A zero in this field is undefined. Integrated RMH - If USB_R is disabled, this should be updated by BIOS to 2 such that the EHC reports 2ports to be default, port 0 assigned to the RMH and port 1 assigned to the debug device. If USB-R is enabled, the number reported should be updated to 3 by BIOS (port 2 will be assigned to USB-R in this case) Legacy Mode - The default value for the EHCI controller indicates 8 ports. If USB-R support is enabled, BIOS should account for the additional ports in calculating the value to write to this field. Power Well: Resume

18.9.3 Host Controller Capability Parameters (HCCPARAMS)—Offset 8h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 8h

MBAR Type: PCI Configuration Register (Size: 32 bits)

MBAR Reference: [B:0, D:29, F:0] + 10h

Default: 00036881h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	1
RSVD				ASPFC_0	PSPFC_0	EECP_0	IST_0	RSVD
								ASPC_0
								PFLF_0
								AC64_0

Bit Range	Default & Access	Field Name (ID): Description
31:18	00000000 00000b RO	Reserved (RSVD): Reserved.
17	1b RW	Asynchronous Schedule Prefetch Capability (ASPFC_0): This bit indicates that the hardware support the Asynch schedule prefetch enable bit in the USB command register. Power Well: Resume
16	1b RW	Periodic Schedule Prefetch Capability (PSPFC_0): This bit indicates that the EHC hardware supports the Periodic Schedule prefetch bit in the USB2 Command Register. Power Well: Core
15:8	68h RO	EHCI Extended Capabilities Pointer (EECP_0): This field is hardwired to 68h, indicating that the EHCI capabilities list exists and begins at offset 68h in the PCI configuration space. Power Well: Resume
7:4	8h RO	Isochronous Scheduling Threshold (IST_0): This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. Refer to the EHCI specification for details on how software uses this information for scheduling isochronous transfers. The Intel USB2 hardwires this field to 8h. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Reserved (RSVD): Reserved.
23:16	08h RW	Interrupt Threshold Control (ITC_0): This field is used by system software to select the maximum rate at which the host controller will issue interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined. Value Maximum Interrupt Interval 00h Reserved 01h 1 micro-frame 02h 2 micro-frames 04h 4 micro-frames 08h 8 micro-frames (default, equates to 1 ms) 10h 16 micro-frames (2 ms) 20h 32 micro-frames (4 ms) 40h 64 micro-frames (8 ms) Refer to Section 4 in the EHCI specification for interrupts affected by this field. Power Well: Core
15:14	00b RO	Reserved (RSVD): Reserved.
13	0b RO	Reserved (RSVD): Reserved.
12	0h RO	Reserved (RSVD): Reserved.
11:8	0h RO	Unimplemented Asynchronous Park Mode Bits (UAPMB_0): This field is hardwired to 000b because the host controller does not support this optional feature. Power Well: Core
7	0b RO	Light Host Controller Reset (LHCR_0): Read Only 0b. The Intel EHC does not implement this optional reset and hardwires this bit to 0. Power Well: Core
6	0b RW	Interrupt on Async Advance Doorbell (IAAD_0): This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule state, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Async Advance Enable bit in the USBINTR register is a one then the host controller will assert an interrupt at the next interrupt threshold. See the EHCI specification for operational details. The host controller sets this bit to a zero after it has set the Interrupt on Async Advance status bit in the USBSTS register to a one. Software should not write a one to this bit when the asynchronous schedule is disabled. Doing so will yield undefined results. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
5	0b RW	Asynchronous Schedule Enable (ASE_0): This bit controls whether the host controller skips processing the Asynchronous Schedule. Values mean: 0b Do not process the Asynchronous Schedule 1b Use the ASYNCLISTADDR register to access the Asynchronous Schedule. Power Well: Core
4	0b RW	Periodic Schedule Enable (PSE_0): This bit controls whether the host controller skips processing the Periodic Schedule. Values mean: 0b Do not process the Periodic Schedule 1b Use the PERIODICLISTBASE register to access the Periodic Schedule. Power Well: Core
3:2	00b RO	Frame List Size (FLS_0): This field is R/W only if Programmable Frame List Flag in the HCCPARAMS registers is set to a one. . This field specifies the size of the frame list. The size the frame list controls which bits in the Frame Index Register should be used for the Frame List Current index. Values mean: 00b 1024 elements (4096 bytes) Default value; 01b 512 elements (2048 bytes); 10b 256 elements (1024 bytes) - for resource-constrained environments Power Well: Core
1	0b RW	Host Controller Reset (HCRESET_0): This control bit used by software to reset the host controller. The effects of this on Root Hub registers are similar to a Chip Hardware Reset. When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Note: PCI Configuration registers and Host Controller Capability Registers are not affected by this reset. All operational registers, including port registers and port state machines are set to their initial values. Port ownership will be disowned by the host controller(s), with the side effects described in the EHCI spec. Software must reinitialize the host controller in order to return the host controller to an operational state. This bit is set to zero by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. This reset must be used to leave EHCI port test modes. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
0	0b RW	Run/Stop (RS_0): 1=Run. 0=Stop. When set to a 1, the Host Controller proceeds with execution of the schedule. The Host Controller continues execution as long as this bit is set to a 1. When this bit is set to 0, the Host Controller completes the current and any actively pipelined transactions on the USB and then halts. The Host Controller must halt within 16 microframes after software clears the Run bit. The HC Halted bit in the status register indicates when the Host Controller has finished its pending pipelined transactions and has entered the stopped state. Software should not write a 1 to this field unless the host controller is in the Halted state (i.e. HCHalted in the USBSTS register is a one). The following table explains how the different combinations of Run and Halted must be interpreted: Run/Stop Halted Interpretation 0 0 Valid- in the process of halting 0 1 Valid- halted 1 0 Valid- running 1 1 Invalid- the HCHalted bit clears immediately Memory read cycles initiated by the EHC that receive any status other than Successful will result in this bit being cleared (and also affect the Host Error bit). Power Well: Core

18.9.5 USB2 Status (USB2STS)—Offset 24h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 24h**MBAR Type:** PCI Configuration Register (Size: 32 bits)

MBAR Reference: [B:0, D:29, F:0] + 10h

Default: 00001000h

31	28	24	20	16	12	8	4	0						
0	0	0	0	0	0	0	0	0						
RSVD				ASS_0	PSS_0	RECL_0	HCHALT_0	RSVD	IAA_0	HSE_0	FLR_0	PCD_0	USBBERRINT_0	USBBERRINT_0

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Reserved (RSVD): Reserved.

Bit Range	Default & Access	Field Name (ID): Description
15	0b RO	Asynchronous Schedule Status (ASS_0): This bit reports the current real status of the Asynchronous Schedule. If this bit is a zero then the status of the Asynchronous Schedule is disabled. If this bit is a one then the status of the Asynchronous Schedule is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Power Well: Core
14	0b RO	Periodic Schedule Status (PSS_0): This bit reports the current real status of the Periodic Schedule. If this bit is a zero then the status of the Periodic Schedule is disabled. If this bit is a one then the status of the Periodic Schedule is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). The Prefetch-Based Pause feature prevents this bit from transitioning to 0 if it currently has a request pending, in addition to the regular Periodic DMA engine. Power Well: Core
13	0b RO	Reclamation (RECL_0): This is a read-only status bit, which is used to detect an empty asynchronous schedule. The operational model and valid transitions for this bit are described in Section 4 of the EHCI Specification. Power Well: Core
12	1b RO	HCHalted (HCHALT_0): This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to 1 after it has stopped executing as a result of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g. internal error). The Prefetch-Based Pause feature prevents this bit from transitioning to 0 if it is currently has a request pending, in addition to the regular DMA engines. Power Well: Core
11:6	000000b RO	Reserved (RSVD): Reserved.
5	0b RWC	Interrupt on Async Advance (IAA_0): System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
4	0b RWC	Host System Error (HSE_0): The Host Controller sets this bit to 1 when a serious error occurs during a host system access involving the Host Controller module. Memory read cycles initiated by the EHC that receive any status other than Successful will result in this bit being set. When this error occurs, the Host Controller clears the Run/Stop bit in the Command register to prevent further execution of the scheduled TDs. A hardware interrupt is generated to the system (if enabled in the Interrupt Enable Register). Power Well: Core
3	0b RWC	Frame List Rollover (FLR_0): The Host Controller sets this bit to a one when the Frame List Index (see Section 9.3.2.4) rolls over from its maximum value to zero. Since the USB2 SIP only supports the 1024-entry Frame List Size, the Frame List Index rolls over every time FRNUM[13] toggles. Power Well: Core
2	0b RWC	Port Change Detect (PCD_0): The Host Controller sets this bit to a one when any port for which the Port Owner bit is set to zero has a change bit transition from a zero to a one or a Force Port Resume bit transition from a zero to a one as a result of a J-K transition detected on a suspended port. This bit will also be set as a result of the Connect Status Change being set to a one after system software has relinquished ownership of a connected port by writing a zero to a port's Port Owner bit. This bit is allowed to be maintained in the Auxiliary power well. Alternatively, it is also acceptable that on a D3 to D0 transition of the EHCI HC device, this bit is loaded with the OR of all of the PORTSC change bits (including: Force port resume, over-current change, enable/disable change and connect status change). Regardless of the implementation, whenever this bit is readable (i.e., in the D0 state), it must provide a valid view of the Port Status registers. Power Well: Core
1	0b RWC	USB Error Interrupt (USBERRINT_0): The Host Controller sets this bit to 1 when completion of a USB transaction results in an error condition (e.g., error counter underflow). If the TD on which the error interrupt occurred also had its IOC bit set, both this bit and Bit 0 are set. See the EHCI specification for a list of the USB errors that will result in this interrupt being asserted. Power Well: Core
0	0b RWC	USB Interrupt (USBINT_0): The Host Controller sets this bit to 1 on the completion of a USB transaction, which results in the retirement of a Transfer Descriptor that had its IOC bit set. The Host Controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes). Power Well: Core

18.9.6 USB2 Interrupt Enable (USB2INTR)—Offset 28h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 28h

MBAR Type: PCI Configuration Register (Size: 32 bits)

18.9.10 Current Asynchronous List Address (ASYNCLISTADDR)—Offset 38h

Intel Atom® Processor E3800 Product Family
Datasheet
2389

Bit Range	Default & Access	Field Name (ID): Description
0	0b RW	Configure Flag (CF_0): Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic. Bit values and side-effects are listed below. See section 4 of the EHCI spec for operation details. 0b Port routing control logic default-routes each port to the classic host controllers. 1b Port routing control logic default-routes all ports to this host controller. This register is in the suspend power well. It is only reset by hardware when the suspend power is initially applied or in response to a host controller reset. Power Well: Resume

18.9.12 Port Status and Control (PORTSC1)—Offset 64h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 64h**MBAR Type:** PCI Configuration Register (Size: 32 bits)

MBAR Reference: [B:0, D:29, F:0] + 10h

Default: 00003000h

[illegible]

Bit Range	Default & Access	Field Name (ID): Description
31:23	000h RO	Reserved (RSVD): Reserved.
22	0b RW	Wake on Over-current Enable (WKOCE_P0_0): Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Over-current Active bit (bit 4 of this register) is set. Power Well: Resume
21	0b RW	Wake on Disconnect Enable (WKDSCNTE_P0_0): Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from connected to disconnected (i.e., bit 0 of this register changes from 1 to 0). Power Well: Resume
20	0b RW	Wake on Connect Enable (WKCENTE_P0_0): Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from disconnected to connected (i.e., bit 0 of this register changes from 0 to 1). Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
19:16	0h RW	Port Test Control (PTC_P0_0): When this field is zero, the port is NOT operating in a test mode. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. The encoding of the test mode bits are (0110b - 1111b are reserved): Bits Test Mode 0000b Test mode not enabled 0001b Test J_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0010b Test K_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0011b Test SE0_NAK 0100b Test Packet 0101b Test FORCE_ENABLE Refer to USB Specification Revision 2.0, Chapter 7 and the EHCI specification, Chapter 4 for details on each test mode. The EHC does not support the option to run the port tests while the Run/Stop bit is a one. Power Well: Resume
15:14	00b RW	Port Indicator Control (PIC_P0_0): Writing to these bits directly controls the corresponding LED output pins. Bit 15 is inverted to generate USBLEDG#(n) where n is the port number. Bit 14 is inverted to generate USBLEDA#(n). Software is responsible for controlling these as specified in the USB Specification Revision 2.0. Bit Value Meaning 00b Port indicators are off 01b Amber 10b Green 11b Undefined The Intel EHC only supports bit value of 00b. Other values will result in unspecified behavior. Power Well: Resume
13	1b RW	Port Owner (PO_P0_0): This bit unconditionally goes to a 0b when the Configure Flag makes a 0b to 1b transition. This bit unconditionally goes to 1b whenever the Configure Flag bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that a companion host controller owns and controls the port. See Section 4 of the EHCI Specification for operational details. Power Well: Resume
12	1b RO	Port Power (PP_P0_0): Hard-wired with a value of '1' on the Intel EHC. This indicates that the port does have power. Power Well: Resume
11:10	00b RO	Line Status (LS_P0_0): These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. These bits are used for detection of low-speed USB devices prior to the port reset and enable sequence. This field is valid only when the port enable bit is zero and the current connect status bit is set to a one. The encoding of the bits are: Bits(11:10) USB State Interpretation 00b SE0 Not Low-speed device, perform EHCI reset 10b J-state Not Low-speed device, perform EHCI reset 01b K-state Low-speed device, release ownership of port 11b Undefined Not Low-speed device, perform EHCI reset Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
9	0b RO	Reserved (RSVD): Reserved.
8	0b RW	Port Reset (PORTRST_P0_0): 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared. Power Well: Resume
7	0b RW	Suspend (SUSP_P0_0): 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
6	0b RW	Force Port Resume (FPR_P0_0): 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero. Power Well: Resume
5	0b RWC	Over-current Change (OCC_P0_0): This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner. Power Well: Resume
4	0b RO	Over-current Active (OACT_P0_0): 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'. Power Well: Resume
3	0b RWC	Port Enable/Disable Change (PEDC_P0_0): 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it. Power Well: Resume
2	0b RO	Reserved (RSVD): Reserved.

18.9.13 Port Status and Control (PORTSC2)—Offset 68h

Bit Range	Default & Access	Field Name (ID): Description
21	0b RW	Wake on Disconnect Enable (WKDSCNTE_P0_0): Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from connected to disconnected (i.e., bit 0 of this register changes from 1 to 0). Power Well: Resume
20	0b RW	Wake on Connect Enable (WKCNNTE_P0_0): Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from disconnected to connected (i.e., bit 0 of this register changes from 0 to 1). Power Well: Resume
19:16	0h RW	Port Test Control (PTC_P0_0): When this field is zero, the port is NOT operating in a test mode. Bit Value Meaning 00b Port indicators are off 01b Amber 10b Green 11b Undefined The Intel EHC only supports bit value of 00b. Other values will result in unspecified behavior. Power Well: Resume
13	1b RW	Port Owner (PO_P0_0): This bit unconditionally goes to a 0b when the Configure Flag makes a 0b to 1b transition. This bit unconditionally goes to 1b whenever the Configure Flag bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that a companion host controller owns and controls the port. See Section 4 of the EHCI Specification for operational details. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
12	1b RO	Port Power (PP_P0_0): Hard-wired with a value of '1' on the Intel EHC. This indicates that the port does have power. Power Well: Resume
11:10	00b RO	Line Status (LS_P0_0): These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. These bits are used for detection of low-speed USB devices prior to the port reset and enable sequence. This field is valid only when the port enable bit is zero and the current connect status bit is set to a one. The encoding of the bits are: Bits(11:10) USB State Interpretation 00b SE0 Not Low-speed device, perform EHCI reset 10b J-state Not Low-speed device, perform EHCI reset 01b K-state Low-speed device, release ownership of port 11b Undefined Not Low-speed device, perform EHCI reset Power Well: Resume
9	0b RO	Reserved (RSVD): Reserved.
8	0b RW	Port Reset (PORTRST_P0_0): 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
7	0b RW	Suspend (SUSP_P0_0): 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined. Power Well: Resume
6	0b RW	Force Port Resume (FPR_P0_0): 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero. Power Well: Resume
5	0b RWC	Over-current Change (OCC_P0_0): This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
4	0b RO	Over-current Active (OACT_P0_0): 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'. Power Well: Resume
3	0b RWC	Port Enable/Disable Change (PEDC_P0_0): 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it. Power Well: Resume
2	0b RO	Reserved (RSVD): Reserved.
1	0b RWC	Connect Status Change (CSC_P0_0): 1=Change in Current Connect Status. 0=No change. Indicates a change has occurred in the port's Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software sets this bit to 0 by writing a 1 to it. Power Well: Resume
0	0b RO	Current Connect Status (CCS_P0_0): 1=Device is present on port. 0=No device is present. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
19:16	0h RW	Port Test Control (PTC_P0_0): When this field is zero, the port is NOT operating in a test mode. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. The encoding of the test mode bits are (0110b - 1111b are reserved): Bits Test Mode 0000b Test mode not enabled 0001b Test J_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0010b Test K_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0011b Test SE0_NAK 0100b Test Packet 0101b Test FORCE_ENABLE Refer to USB Specification Revision 2.0, Chapter 7 and the EHCI specification, Chapter 4 for details on each test mode. The EHC does not support the option to run the port tests while the Run/Stop bit is a one. Power Well: Resume
15:14	00b RW	Port Indicator Control (PIC_P0_0): Writing to these bits directly controls the corresponding LED output pins. Bit 15 is inverted to generate USBLEDG#(n) where n is the port number. Bit 14 is inverted to generate USBLEDA#(n). Software is responsible for controlling these as specified in the USB Specification Revision 2.0. Bit Value Meaning 00b Port indicators are off 01b Amber 10b Green 11b Undefined The Intel EHC only supports bit value of 00b. Other values will result in unspecified behavior. Power Well: Resume

Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared. Power Well: Resume
7	0b RW	Suspend (SUSP_P0_0): 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
6	0b RW	Force Port Resume (FPR_P0_0): 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero. Power Well: Resume
5	0b RWC	Over-current Change (OCC_P0_0): This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner. Power Well: Resume
4	0b RO	Over-current Active (OACT_P0_0): 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'. Power Well: Resume
3	0b RWC	Port Enable/Disable Change (PEDC_P0_0): 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it. Power Well: Resume
2	0b RO	Reserved (RSVD): Reserved.

18.9.19 Port Status and Control (PORTSC8)—Offset 80h

Bit Range	Default & Access	Field Name (ID): Description
1	0b RWC	Connect Status Change (CSC_P0_0): 1=Change in Current Connect Status. 0=No change. Indicates a change has occurred in the port's Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software sets this bit to 0 by writing a 1 to it. Power Well: Resume
0	0b RO	Current Connect Status (CCS_P0_0): 1=Device is present on port. 0=No device is present. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. Power Well: Resume

18.9.19 Port Status and Control (PORTSC8)—Offset 80h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + 80h**MBAR Type:** PCI Configuration Register (Size: 32 bits)

MBAR Reference: [B:0, D:29, F:0] + 10h

Default: 00003000h

[illegible]

Bit Range	Default & Access	Field Name (ID): Description
31:23	000h RO	Reserved (RSVD): Reserved.
22	0b RW	Wake on Over-current Enable (WKOCE_P0_0): Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Over-current Active bit (bit 4 of this register) is set. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
21	0b RW	Wake on Disconnect Enable (WKDSCNTE_P0_0): Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from connected to disconnected (i.e., bit 0 of this register changes from 1 to 0). Power Well: Resume
20	0b RW	Wake on Connect Enable (WKCNNTE_P0_0): Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from disconnected to connected (i.e., bit 0 of this register changes from 0 to 1). Power Well: Resume
19:16	0h RW	Port Test Control (PTC_P0_0): When this field is zero, the port is NOT operating in a test mode. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. The encoding of the test mode bits are (0110b - 1111b are reserved): Bits Test Mode 0000b Test mode not enabled 0001b Test J_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0010b Test K_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0011b Test SE0_NAK 0100b Test Packet 0101b Test FORCE_ENABLE Refer to USB Specification Revision 2.0, Chapter 7 and the EHCI specification, Chapter 4 for details on each test mode. The EHC does not support the option to run the port tests while the Run/Stop bit is a one. Power Well: Resume
15:14	00b RW	Port Indicator Control (PIC_P0_0): Writing to these bits directly controls the corresponding LED output pins. Bit 15 is inverted to generate USBLEDG#(n) where n is the port number. Bit 14 is inverted to generate USBLEDA#(n). Software is responsible for controlling these as specified in the USB Specification Revision 2.0. Bit Value Meaning 00b Port indicators are off 01b Amber 10b Green 11b Undefined The Intel EHC only supports bit value of 00b. Other values will result in unspecified behavior. Power Well: Resume
13	1b RW	Port Owner (PO_P0_0): This bit unconditionally goes to a 0b when the Configure Flag makes a 0b to 1b transition. This bit unconditionally goes to 1b whenever the Configure Flag bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that a companion host controller owns and controls the port. See Section 4 of the EHCI Specification for operational details. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
12	1b RO	Port Power (PP_P0_0): Hard-wired with a value of '1' on the Intel EHC. This indicates that the port does have power. Power Well: Resume
11:10	00b RO	Line Status (LS_P0_0): These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. These bits are used for detection of low-speed USB devices prior to the port reset and enable sequence. This field is valid only when the port enable bit is zero and the current connect status bit is set to a one. The encoding of the bits are: Bits(11:10) USB State Interpretation 00b SE0 Not Low-speed device, perform EHCI reset 10b J-state Not Low-speed device, perform EHCI reset 01b K-state Low-speed device, release ownership of port 11b Undefined Not Low-speed device, perform EHCI reset Power Well: Resume
9	0b RO	Reserved (RSVD): Reserved.
8	0b RW	Port Reset (PORTRST_P0_0): 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
7	0b RW	Suspend (SUSP_P0_0): 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when: Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined. Power Well: Resume
6	0b RW	Force Port Resume (FPR_P0_0): 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero. Power Well: Resume
5	0b RWC	Over-current Change (OCC_P0_0): This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner. Power Well: Resume

Bit Range	Default & Access	Field Name (ID): Description
4	0b RO	Over-current Active (OACT_P0_0): 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'. Power Well: Resume
3	0b RWC	Port Enable/Disable Change (PEDC_P0_0): 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it. Power Well: Resume
2	0b RO	Reserved (RSVD): Reserved.
1	0b RWC	Connect Status Change (CSC_P0_0): 1=Change in Current Connect Status. 0=No change. Indicates a change has occurred in the port's Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software sets this bit to 0 by writing a 1 to it. Power Well: Resume
0	0b RO	Current Connect Status (CCS_P0_0): 1=Device is present on port. 0=No device is present. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. Power Well: Resume

18.9.20 Debug Port Control/Status Register (DP_CTRLSTS)— Offset A0h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [MBAR] + A0h

MBAR Type: PCI Configuration Register (Size: 32 bits)

MBAR Reference: [B:0, D:29, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RSVD	OWNERCNT_0	RSVD	RSVD	DONESTS_0	LINKIDSTS_0	RSVD	ERRGOODSTS_0	DATALENCNT_0

Bit Range	Default & Access	Field Name (ID): Description
31	0b RO	Reserved (RSVD): Reserved.
30	0b RW	OWNER_CNT (OWNERCNT_0): When software writes a 1 to this bit, the ownership of the debug port is forced to the EHCI controller (i.e. immediately taken away from the companion Classic USB Host Controller) If the port was already owned by the EHCI controller, then setting this bit has no effect. This bit overrides all of the ownership-related bits in the standard EHCI registers. Note that the value in this bit does not affect the value reported in the PORTSC Port Owner bit. Power Well: Core
29	0b RO	Reserved (RSVD): Reserved.
28	0b RW	ENABLED_CNT (ENABLEDCNT_0): This bit = 1 if the debug port is enabled for operation. Software can clear this by writing a zero to it. The hardware clears the bit for the same conditions where hardware clears the Port Enable/Disable bit (in the PORTSC register). (Note this bit is not cleared when software clears the Port Enabled/Disabled bit in the PORTSC.) Software can directly set this bit if the port is already enabled in the associated Port Status and Control register (this is enforced by the hardware). Reset default = 0. Power Well: Core
27:17	000000000 00b RO	Reserved (RSVD): Reserved.

Bit Range	Default & Access	Field Name (ID): Description
16	0b RWC	DONE_STS (DONESTS_0): Read/Write-Clear. This bit is set by hardware to indicate that the request is complete. Writing a 1 to this bit will clear it if it is set. Writing a 0 to this bit has no effect. Reset default = 0 Power Well: Core
15:12	0000b RO	LINK_ID_STS (LINKIDSTS_0): Read-Only. This field identifies the link interface. It is hardwired to 0h to indicate that it is a USB Debug Port. Power Well: Core
11	0b RO	Reserved (RSVD): Reserved.
10	0b RO	IN_USE_CNT (INUSECNT_0): Set by software to indicate that the port is in use. Cleared by software to indicate that the port is free and may be used by other software. This bit is cleared after reset. (This bit has no affect on hardware.) Power Well: Core
9:7	000b RO	EXCEPTION_STS (EXCP_STS_0): Read-Only. This field indicates the exception when the ERROR_GOOD#_STS bit is set. This field should be ignored if the ERROR_GOOD#_STS bit is 0. 000 No Error. Note: this should not be seen, since this field should only be checked if there is an error. 001 Transaction error: indicates the USB2 transaction had an error (CRC, bad PID, timeout, etc.) 010 HW error. Request was attempted (or in progress) when port was suspended or reset. All Others are reserved Reset default = 000b Power Well: Core
6	0b RO	ERROR_GOOD_STS (ERRGOODSTS_0): Read-Only. The hardware clears this bit to 0 upon the proper completion of a read or write. The hardware sets this bit to indicate that an error has occurred. Details on the nature of the error are provided in the Exception field. Reset default = 0. Power Well: Core
5	0b RW	GO_CNT (GOCNT_0): Software sets this bit to cause the hardware to perform a read or write request. Writing a 0 to this bit has no effect. Writing a 1 to this bit when it is already set may result in undefined behavior. When set, the hardware clears this bit when the hardware sets the DONE_STS bit. Reset default = 0. Power Well: Core
4	0b RW	WRITE_READ_CNT (WRRDCNT_0): Software sets this bit to indicate that the current request is a write. Software clears this bit to indicate that the current request is a read. Reset default = 0. Power Well: Core

Bit Range	Default & Access	Field Name (ID): Description
3:0	0000b RW	DATA_LEN_CNT (DATALENCNT_0): This field is used to indicate the size of the data to be transferred. Reset default = 0h. For write operations, this field is set by software to indicate to the hardware how many bytes of data in Data Buffer are to be transferred to the console. A value of 0h indicates that a zero-length packet should be sent. A value of 1-8 indicates 1-8 bytes are to be transferred. Values 9-Fh are illegal and how hardware behaves if used is undefined. For read operations, this field is set by hardware to indicate to software how many bytes in Data Buffer are valid in response to a read operation. A value of 0h indicates that a zero length packet was returned and the state of Data Buffer is not defined. A value of 1-8 indicates 1-8 bytes were received. Hardware is not allowed to return values 9-Fh. The transferring of data always starts with byte 0 in the data area and moves toward byte 7 until the transfer size is reached. Power Well: Core

18.9.21 USB PIDs Register (DP USB PIDs)—Offset A4h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

19 USB Device Controller Interfaces (3.0, ULPI)

The SoC implements a single USB 3.0 device controller, where the platform acts as a peripheral to another device or another PC.

The USB Device controller supports connections at Super Speed (3.0) on the USB3DEV interface, and High and Full speeds (2.0/1.x) on the ULPI interface. To support High and Full Speed devices on ULPI, an external PHY is required.

Note: The ULPI interface must be implemented even if only SuperSpeed support is required. The USB3DEV interface will not operate if the ULPI interface is disabled.

19.0.1 Signal Descriptions

See [Chapter 2, “Physical Interfaces”](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal’s function

Table 217. USB 3.0 Device Signals

Signal Name	Direction Plat. Power	Description
USB3DEV_RXP/N[0]	I V1P0S	Data In: High speed serialized data inputs
USB3DEV_TXP/N[0]	O V1P0S	Data Out: High speed serialized data outputs.
USB3DEV_REXT[0]		Resistor Compensation: An external resistor must be connected between this pin and package ground. Contact your Intel representative for details.

Table 218. USB ULPI Device Signals

Signal Name	Direction Plat. Power	Description
USB_ULPI_CLK	I V1P8A	Interface Clock By default, control and data signals are synchronous to clock.
USB_ULPI_DATA[7:0]	I/O V1P8A	Bi-directional data bus Driven low by the Link during idle. The Link starts a transfer by sending a non-zero pattern. The PHY must assert USB_ULPI_DIR before using the data bus. A turnaround cycle is required every time that USB_ULPI_DIR toggles.
USB_ULPI_DIR	I V1P8A	Direction of the data bus By default, USB_ULPI_DIR is low and the PHY listens for non-zero data from the Link. The PHY asserts USB_ULPI_DIR to get control of the data bus.
USB_ULPI_NXT	I V1P8A	Next Data The PHY drives USB_ULPI_NXT high to throttle the data bus
USB_ULPI_STP	O V1P8A	Stop data The Link drives USB_ULPI_STP high to signal the end of its data stream. The Link can also drive USB_ULPI_STP high to request data bus access from the PHY
USB_ULPI_REFCLK	O V1P8A	Reference clock ULPI reference clock for external PHY
USB_ULPI_RST#	O V1P8A	Reset Used to reset the external PHY. Not part of ULPI specification. Optionally used by driver.

19.1 USB Device Controller

The USB device controller can control one USB 3.0 Device port. Either a combo SS + ULPI Device port, or UPLI only port. It supports hosts conforming to USB 3.0 at bit rates up to 5 Gbps on USB3DEV interface as well as USB 2.0 hosts at up to 480 Mbps via a PHY on ULPI.

19.1.1 Features

Features supported by the Device Controller include:

- Enumerated by both ACPI and PCI. The USB3 device subsystem is designed to appear to the OS as a true PCI device. It will also support ACPI-enumerated methods.
- Device controller registers and data structures are implemented as extensions to the EHCI programmers interface.
- Support for LPM (Link Power Management)

Some of the key features of the ULPI device controller are:

- Supports up to 8 endpoints when acting as device
- 8-bit data interface transmitted at 60 MHz ULPI clock

Note: Recommended not to disconnect the connection when a debug session is in progress.

19.1.2 Power Management Features

The USB 3.0 device subsystem supports the following device power states:

- D0: Functional and highest power state.
- RTD3 (D3): Software managed deepest low power state in which state is saved/restored if needed prior to entry/exit

19.1.2.1 D0

This is the Functional and highest power state. The USB 3.0 device subsystem is in this state when the USB link is in U0 (U0 is the normal operational state where packets can be transmitted and received).

19.1.2.2 D3

D3 is a low power state that is used when the link is suspended; for example, U3 (U3 is a link state where a device is put into a suspend state. Significant link and device powers are saved).

This is a software directed state in which the controller is either power gated or the power is disabled.

19.1.3 Interrupts

A Functional Interrupt is generated by the logic in the USB device controller core to indicate the occurrence of an event needing application intervention. The design of the USB device core is such that events such as "link change" that would traditionally trigger an interrupt through an interrupt status register, are instead delivered to an 'Event buffer' in host memory, together with an interrupt indicating this.

19.3 Register Map

See Chapters [Section 3, "Register Access Methods" on page 69](#) and [Section 4, "Mapping Address Spaces" on page 75](#) for additional information. Also note that the device controller also contains both device and host registers. The host functionality of this controller is not fully functional and should not be used. See the USB Host chapter for host controllers.

19.4.4 reg_CLLATHEADERBIST_type (CLLATHEADERBIST)—Offset Ch

CLLATHEADERBIST - Cache Line Latency Header and BIST

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

CLLATHEADERBIST: [B:0, D:22, F:0] + Ch

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
Reserved0			MULFNDEV	HEADERTYPE		LATTIMER	CACHELINE_SIZE	

Bit Range	Default & Access	Description
31:24	00h RO	Reserved0: Reserved.
23	0h RO	MULFNDEV: Reserved.
22:16	00h RO	HEADERTYPE: Reserved.

Bit Range	Default & Access	Description
15:8	00h RO	LATTIMER: Reserved.
7:0	00h RW	CACHELINE_SIZE: Reserved.

19.4.5 reg_BAR_type (BAR)—Offset 10h

BAR -Base Address Register

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

BAR: [B:0, D:22, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
BASEADDR						SIZEINDICATOR		
PREFETCHABLE			TYPE			MESSAGE SPACE		

Bit Range	Default & Access	Description
31:12	00000h RW	BASEADDR: Reserved.
11:4	00h RO	SIZEINDICATOR: Reserved.
3	0h RO	PREFETCHABLE: Reserved.
2:1	0h RO	TYPE: Reserved.
0	0h RO	MESSAGE_SPACE: Reserved.

19.4.6 reg_BAR1_type (BAR1)—Offset 14h

BAR1 -Base Address Register1

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

BAR1: [B:0, D:22, F:0] + 14h

Default: 00000000h

Bit Range	Default & Access	Description
31:12	00000h RW	BASEADDR1: Reserved.
11:4	00h RO	SIZEINDICATOR1: Reserved.
3	0h RO	PREFETCHABLE1: Reserved.
2:1	0h RO	TYPE1: Reserved.
0	0h RO	MESSAGE_SPACE1: Reserved.

19.4.7 reg_SUBSYSTEMID_type (SUBSYSTEMID)—Offset 2Ch

SUBSYSTEMID -Subsystem Vendor and Subsystem ID

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

SUBSYSTEMID: [B:0, D:22, F:0] + 2Ch

Default: 00000000h

Bit Range	Default & Access	Description
31:16	0000h RW/O	SUBSYSTEMID: Reserved.
15:0	0000h RW/O	SUBSYSTEMVENDORID: Reserved.

Access Method

INTERRUPTREG: [B:0, D:22, F:0] + 3Ch

	31	28	24	20	16	12	8	4	0
	0	0	0	0	0	0	0	0	0
	MAX_LAT		MIN_GNT		Reserved0		INTPIN		INTLINE

Bit Range	Default & Access	Description
31:24	00h RO	MAX_LAT: Reserved.
23:16	00h RO	MIN_GNT: Reserved.
15:12	0h RO	Reserved0: Reserved.
11:8	1h RO	INTPIN: Reserved.
7:0	00h RW	INTLINE: Reserved.

19.4.11 reg_POWERCAPID_type (POWERCAPID)—Offset 80h

Access Method

POWERCAPID: [B:0, D:22, F:0] + 80h

31				28				24				20				16				12				8				4				0			
0	1	0	0	1	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
PMESUPPORT				Reserved0				VERSION				NXTCAP				POWER_CAP																			

Bit Range	Default & Access	Description
31:27	09h RO	PMESUPPORT: Reserved.
26:19	00h RO	Reserved0: Reserved.

Bit Range	Default & Access	Description
18:16	3h RO	VERSION: Reserved.
15:8	00h RO	NXTCAP: Reserved.
7:0	01h RO	POWER_CAP: Reserved.

19.4.12 reg_PMECTRLSTATUS_type (PMECTRLSTATUS)—Offset 84h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

PMCTRLSTATUS: [B:0, D:22, F:0] + 84h

Default: 00000008h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
Reserved0				PMESTATUS	Reserved1		PMEENABLE	Reserved2
								NO_SOFT_RESET
								Reserved3
								POWERSTATE

Bit Range	Default & Access	Description
31:16	0000h RO	Reserved0: Reserved.
15	0h RW/1C	PMESTATUS: Reserved.
14:9	00h RO	Reserved1: Reserved.
8	0h RW	PMEENABLE: Reserved.
7:4	0h RO	Reserved2: Reserved.
3	1h RO	NO_SOFT_RESET: Reserved.
2	0h RO	Reserved3: Reserved.
1:0	0h RW	POWERSTATE: Reserved.

19.4.13 reg_MANID_type (MANID)—Offset F8h

Manufacturers ID

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

STATUSCOMMAND: [B:0, D:22, F:0] + 4h

Default: 00100000h

31		28		24				20				16				12				8				4				0									
0		0		0		0		0		0		1		0		0		0		0		0		0		0		0									
Reserved0		RMA		RCA		Reserved1				CAPLIST		INTR_STATUS		Reserved2				Reserved3				INTR_DISABLE		Reserved4		SERR_ENABLE		Reserved5				BME		MSE		Reserved6	

Bit Range	Default & Access	Description
31:30	0h RO	Reserved0: Reserved.
29	0h RW/1C	RMA: Reserved.
28	0h RW/1C	RCA: Reserved.
27:21	00h RO	Reserved1: Reserved.
20	1h RO	CAPLIST: Reserved.
19	0h RO	INTR_STATUS: Reserved.
18:16	0h RO	Reserved2: Reserved.
15:11	00h RO	Reserved3: Reserved.
10	0h RW	INTR_DISABLE: Reserved.
9	0h RO	Reserved4: Reserved.
8	0h RW	SERR_ENABLE: Reserved.
7:3	00h RO	Reserved5: Reserved.
2	0h RW	BME: Reserved.
1	0h RW	MSE: Reserved.
0	0h RO	Reserved6: Reserved.

19.5.3 reg_REVCLASSCODE_type (REVCLASSCODE)—Offset 8h

REVCLASSCODE - Revision ID and Class Code

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

REVCLASSCODE: [B:0, D:22, F:0] + 8h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
CLASS_CODES							RID	

Bit Range	Default & Access	Description
31:8	000000h RO	CLASS_CODES: Reserved.
7:0	00h RO	RID: Reserved.

19.5.4 reg_CLLATHEADERBIST_type (CLLATHEADERBIST)—Offset Ch

CLLATHEADERBIST - Cache Line Latency Header and BIST

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

CLLATHEADERBIST: [B:0, D:22, F:0] + Ch

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
Reserved0		MULFNDEV	HEADERTYPE		LATTIMER	CACHELINE_SIZE		

Bit Range	Default & Access	Description
31:24	00h RO	Reserved0: Reserved.
23	0h RO	MULFNDEV: Reserved.
22:16	00h RO	HEADERTYPE: Reserved.

BAR -Base Address Register

Type: PCI Configuration Register
(Size: 32 bits)

[illegible]

19.5.6 reg_BAR1_type (BAR1)—Offset 14h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

October 2018
Document Number: 538136, Rev. 4.3

Bit Range	Default & Access	Description
31:16	0000h RW/O	SUBSYSTEMID: Reserved.
15:0	0000h RW/O	SUBSYSTEMVENDORID: Reserved.

Access Method

EXPANSION ROM BASEADDR: [B:0, D:22, F:0] + 30h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
EXPANSTON_ROM_BASE								

Bit Range	Default & Access	Description
31:0	00000000h RO	EXPANSION_ROM_BASE: Reserved.

19.5.9 reg_CAPABILITYPTR_type (CAPABILITYPTR)—Offset 34h

CAPABILITYPTR - Capabilities Pointer

Access Method

CAPABILITYPTR: [B:0, D:22, F:0] + 34h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
Reserved0							CAPPTR_POWER	

Bit Range	Default & Access	Description
31:8	000000h RO	Reserved0: Reserved.
7:0	80h RO	CAPPTR_POWER: Reserved.

19.5.10 reg_INTERRUPTREG_type (INTERRUPTREG)—Offset 3Ch

INTERRUPTREG - Interrupt Register

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

INTERRUPTREG: [B:0, D:22, F:0] + 3Ch

Default: 00000100h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	1	0
0	0	0	0	0	0	0	0	0
MAX_LAT				MIN_GNT				INTPIN
				Reserved0				INTLINE

Bit Range	Default & Access	Description
31:24	00h RO	MAX_LAT: Reserved.
23:16	00h RO	MIN_GNT: Reserved.
15:12	0h RO	Reserved0: Reserved.
11:8	1h RO	INTPIN: Reserved.
7:0	00h RW	INTLINE: Reserved.

19.5.11 reg_POWERCAPID_type (POWERCAPID)—Offset 80h

POWERCAPID - PowerManagement Capability ID

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

POWERCAPID: [B:0, D:22, F:0] + 80h

Default: 48030001h

31	28	24	20	16	12	8	4	0
0	1	0	0	1	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
PMESUPPORT				Reserved0				POWER_CAP
				VERSION				
				NXTCAP				

Bit Range	Default & Access	Description
31:27	09h RO	PMESUPPORT: Reserved.
26:19	00h RO	Reserved0: Reserved.

Type: PCI Configuration Register
(Size: 32 bits)

PMCTRLSTATUS: [B:0, D:22, F:0] + 84h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
Reserved0				PMESTATUS	Reserved1		PMEENABLE	Reserved2
								NO_SOFT_RESET
								Reserved3
								POWERSTATE

Bit Range	Default & Access	Description
31:16	0000h RO	Reserved0: Reserved.
15	0h RW/1C	PMESTATUS: Reserved.
14:9	00h RO	Reserved1: Reserved.
8	0h RW	PMEENABLE: Reserved.
7:4	0h RO	Reserved2: Reserved.
3	1h RO	NO_SOFT_RESET: Reserved.
2	0h RO	Reserved3: Reserved.
1:0	0h RW	POWERSTATE: Reserved.

19.5.13 reg_MANID_type (MANID)—Offset F8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

MANID: [B:0, D:22, F:0] + F8h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0
MANID								

Bit Range	Default & Access	Description
31:0	00000000h RO	MANID: Reserved.

19.6.1 CAPLENGTH—Offset 0h

This register is used as an offset to add to register base to find the beginning of the Operational Register Space.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CAPLENGTH: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:22, F:0] + 10h

Default: 00960020h

31	28	24	20	16	12	8	4	0
0	0	0	0	1	0	0	1	0
0	0	0	0	0	1	1	0	0
0	0	0	0	0	0	0	0	0
HCVERSION				RSVD0				CAPLENGTH

Bit Range	Default & Access	Description
31:16	096h RO	HCVERSION: This is a two-byte register containing a BCD encoding of the xHCI specification revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision. e.g. 0100h corresponds to xHCI version 1.0.xs
15:8	0h RO	RSVD0: Reserved.
7:0	20h RO	CAPLENGTH: This register is used as an offset to add to register base to find the beginning of the Operational Register Space.

19.6.2 HCSPARAMS1—Offset 4h

number of ports implemented is 2 because there is 1
DWC_USB2_HOST_NUM_U2_ROOT_PORTS and 1
DWC_USB3_HOST_NUM_U3_ROOT_PORT

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

HCSPARAMS1: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:22, F:0] + 10h

Default: 0200017Fh

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	1	0	1
0	0	1	0	0	0	0	0	0
0	0	0	0	0	0	0	0	1
0	0	0	0	0	0	0	1	0
0	1	1	1	1	1	1	1	1
MAXPORTS				HCSPARAMS1_RSVD1				MAXSLOTS

Bit Range	Default & Access	Description
31:24	02h RO	MAXPORTS: Number of Ports (MaxPorts). This field specifies the maximum Port Number value, i.e. the highest numbered Port Register Set that are addressable in the Operational Register Space (refer to Table 29). Valid values are in the range of 1h to FFh. The value in this field shall reflect the maximum Port Number value assigned by an xHCI Supported Protocol Capability, described in section 7.2. Software shall refer to these capabilities to identify whether a specific Port Number is valid, and the protocol supported by the associated Port Register Set.
23:19	0h RO	HCSPARAMS1_RSVD1: reserved

Bit Range	Default & Access	Description
18:8	1h RO	MAXINTRS: Number of Interrupters (MaxIntrs). This field specifies the number of Interrupters implemented on this host controller. Each Interrupter may be allocated to a MSI or MSI-X vector and controls its generation and moderation. The value of this field determines how many Interrupter Register Sets are addressable in the Runtime Register Space (refer to section 5.5). Valid values are in the range of 1h to 400h. A 0 in this field is undefined.
7:0	7fh RO	MAXSLOTS: Number of Device Slots (MaxSlots). This field specifies the maximum number of Device Context Structures and Doorbell Array entries this host controller can support. Valid values are in the range of 1 to 255. The value of 0 is reserved.

0				0				0				0				0				0				1				1				1				1				0				0				0				0																																			
XECP																MAXPSASIZE																HCCPARAMS_RSVD																SBD				FSE				NSS				LTC				LHRC				PIND				PPC				CSZ				BNC				AC64			

Bit Range	Default & Access	Description
31:16	220h RO	XECP: Based on configuration, core automatically updates it

Bit Range	Default & Access	Description
15:12	fh RO	MAXPSASIZE: Maximum Primary Stream Array Size
11:10	0h RO	HCCPARAMS_RSVD: Reserved
9	0h RO	SBD: Secondary Bandwidth Domain Reporting (SBD)
8	0h RO	FSE: For xHCI 0.96, this field is Force Stopped Event (FSE) / For xHCI 1.0, this field is Parse All Event Data (PAE)
7	0h RO	NSS: No Secondary SID Support (NSS). This flag indicates whether the host controller implementation supports Secondary Stream IDs. A 1 in this bit indicates that Secondary Stream ID decoding is not supported. A 0 in this bit indicates that Secondary Stream ID decoding is supported. (refer to Sections 4.12.2 and 6.2.3).
6	1h RO	LTC: Latency Tolerance Messaging Capability (LTC). This flag indicates whether the host controller implementation supports Latency Tolerance Messaging (LTM). A 1 in this bit indicates that LTM is supported. A 0 in this bit indicates that LTM is not supported. Refer to section 4.13.1 for more information on LTM.
5	0h RO	LHRC: Light HC Reset Capability (LHRC). This flag indicates whether the host controller implementation supports a Light Host Controller Reset. A 1 in this bit indicates that Light Host Controller Reset is supported. A 0 in this bit indicates that Light Host Controller Reset is not supported. The value of this flag affects the functionality of the Light Host Controller Reset (LHCRST) flag in the USBCMD register (refer to Section 5.4.1).
4	0h RO	PIND: Port Indicators (PIND). This bit indicates whether the xHC root hub ports support port indicator control. When this bit is a 1, the port status and control registers include a read/writeable field for controlling the state of the port indicator. Refer to Section 5.4.8 for definition of the Port Indicator Control field.
3	1h RO	PPC: Port Power Control (PPC). This flag indicates whether the host controller implementation includes port power control. A 1 in this bit indicates the ports have port power switches. A 0 in this bit indicates the port do not have port power switches. The value of this flag affects the functionality of the PP flag in each port status and control register (refer to Section 5.4.8).
2	1h RO	CSZ: Context Size (CSZ). If this bit is set to 1, then the xHC uses 64 byte Context data structures. If this bit is cleared to 0, then the xHC uses 32 byte Context data structures. Note: This flag does not apply to Stream Contexts.
1	0h RO	BNC: BW Negotiation Capability (BNC). This flag identifies whether the xHC has implemented the Bandwidth Negotiation. Values for this flag have the following interpretation: for Value 0 Description BW Negotiation not implemented. for Value 1 Description BW Negotiation implemented. Refer to section 4.16 of xHCI specification for more information on Bandwidth Negotiation.
0	0h RO	AC64: 64-bit Addressing Capability (AC64). This flag documents the addressing range capability of this implementation. The value of this flag determines whether the xHC has implemented the high order 32 bits of 64 bit register and data structure pointer fields. Values for this flag have the following interpretation: for Value 0 Description 32-bit address memory pointers implemented. for Value 1 description 64-bit address memory pointers implemented. If 32-bit address memory pointers are implemented, the xHC shall ignore the high order 32 bits of 64 bit data structure pointer fields, and system software shall ignore the high order 32 bits of 64 bit xHC registers.

19.6.6 DBOFF—Offset 14h

Doorbell Offset Register

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

DBOFF: [BAR] + 14h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:22, F:0] + 10h

Bit Range	Default & Access	Description
9	0h RW	CRS: Controller Restore State: This command is similar to the USB_CMD. CRS bit in host mode and initiates the restore process. When software sets this bit to '1', the controller immediately sets DSTS.RSS to '1'. When the controller has finished the restore process, it sets DSTS.RSS to '0'.
8	0h RW	CSS: Controller Save State: This command is similar to the USB_CMD. CSS bit in host mode and initiates the save process. When software sets this bit to '1', the controller immediately sets DSTS.SSS to '1'. When the controller has finished the save process, it sets DSTS.SSS to '0'.
7	0h RW	LHCRST: Light Host Controller Reset (LHCRST) RO or RW. Optional normative. Default = 0. If the Light HC Reset Capability (LHRC) bit in the HCCPARAMS register is 1, then this flag allows the driver to reset the xHC without affecting the state of the ports. A system software read of this bit as 0 indicates the Light Host Controller Reset has completed and it is safe for software to re-initialize the xHC. A software read of this bit as a 1 indicates the Light Host Controller Reset has not yet completed. If not implemented, a read of this flag shall always return a 0. All registers in the Aux Power well shall maintain the values that had been asserted prior to the Light Host Controller Reset. Refer to section 4.23.1 for more information. When this register is exposed by a Virtual Function (VF), this bit only generates a Light Reset to the xHC instance presented by the selected VF, e.g. Disable the VFs device slots and set the associated VF Run bit to Stopped. Refer to section 8 for more information.
6:4	0h RO	RSVD7: Reserved
3	0h RW	HSEE: Host System Error Enable (HSEE) RW. Default = 0. When this bit is a 1, and the HSE bit in the USBSTS register is a 1, the xHC shall assert out-of-band error signaling to the host. The signaling is acknowledged by software clearing the HSE bit. Refer to section 4.10.2.6 for more information. When this register is exposed by a Virtual Function (VF), the effect of the assertion of this bit on the Physical Function (PF0) is determined by the VMM. Refer to section 8 for more information.
2	0h RW	INTE: Interrupter Enable (INTE) RW. Default = 0. This bit provides system software with a means of enabling or disabling the host system interrupts generated by Interrupters. When this bit is a 1, then Interrupter host system interrupt generation is allowed, e.g. the xHC shall issue an interrupt at the next interrupt threshold if the host system interrupt mechanism (e.g. MSI, MSI-X, etc.) is enabled. The interrupt is acknowledged by a host system interrupt specific mechanism. When this register is exposed by a Virtual Function (VF), this bit only enables the set of Interrupters assigned to the selected VF. Refer to section 7.7.2 for more information.
1	0h RW	HCIRST: Host Controller Reset (HCIRST) RW. Default = 0. This control bit is used by software to reset the host controller. The effects of this bit on the xHC and the Root Hub registers are similar to a Chip Hardware Reset. When software writes a 1 to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on the USB is immediately terminated. A USB reset shall not be driven on USB2 downstream ports, however a Hot or Warm Reset shall be initiated on USB3 Root Hub downstream ports. PCI Configuration registers are not affected by this reset. All operational registers, including port registers and port state machines are set to their initial values. Software shall reinitialize the host controller as described in Section 4.1 in order to return the host controller to an operational state. This bit is cleared to 0 by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing a 0 to this bit and shall not write any xHC Operational or Runtime registers until while HCIRST is 1. Note, the completion of the xHC reset process is not gated by the Root Hub port reset process. Software shall not set this bit to 1 when the HCHalted (HCH) bit in the USBSTS register is a 0. Attempting to reset an actively running host controller may result in undefined behavior. When this register is exposed by a Virtual Function (VF), this bit only resets the xHC instance presented by the selected VF. Refer to section 8 for more information.

Bit Range	Default & Access	Description
0	0h RW	R_S: Run/Stop (R/S) RW. Default = 0. 1 = Run. 0 = Stop. When set to a 1, the xHC proceeds with execution of the schedule. The xHC continues execution as long as this bit is set to a 1. When this bit is cleared to 0, the xHC completes any current or queued commands or TDs, and any USB transactions associated with them, then halts. Refer to section 5.4.1.1 for more information on how R/S shall be managed. The xHC shall halt within 16 ms. after software clears the Run/Stop bit if the above conditions have been met. The HCHalted (HCH) bit in the USBSTS register indicates when the xHC has finished its pending pipelined transactions and has entered the stopped state. Software shall not write a 1 to this flag unless the xHC is in the Halted state (i.e. HCH in the USBSTS register is 1). Doing so may yield undefined results. Writing a 0 to this flag when the xHC is in the Running state (i.e. HCH = 0) and any Event Rings are in the Event Ring Full state (refer to section 4.9.4) may result in lost events. When this register is exposed by a Virtual Function (VF), this bit only controls the run state of the xHC instance presented by the selected VF. Refer to section 8 for more information.

19.6.10 USBSTS—Offset 24h

USB Command Register Bit Definitions

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

USBSTS: [BAR] + 24h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:22, F:0] + 10h

31:13	0h RO	RSVD11: reserved
12	0h RO	HCE: Host Controller Error (HCE) - RO. Default = 0. 0' = No internal xHC error conditions exist '1' = Internal xHC error condition. This flag shall be set to indicate that an internal error condition has been detected which requires software to reset and reinitialize the xHC. Refer to section 4.24.1 of xhci specification for more information.
11	0h RO	CNR: Controller Not Ready (CNR) - RO. Default = '1'. '0' = Ready '1' = Not Ready. Software shall not write any Doorbell or Operational register of the xHC, other than the USBSTS register, until CNR = '0'. This flag is set by the xHC after a Chip Hardware Reset and cleared when the xHC is ready to begin accepting register writes. This flag shall remain cleared ('0') until the next Chip Hardware Reset.
10	0h RO	SRE: Save/Restore Error (SRE) -RW1C. Default = '0'. If an error occurs during a Save or Restore operation this bit shall be set to '1'. This bit shall be cleared to '0' when a Save or Restore operation is initiated or when written with '1'. Refer to section 4.23.2 of xhci specification for more information.
9	0h RO	RSS: Restore State Status: This bit is similar to the USBSTS.RSS in host mode. When the controller has finished the save process, it will complete the command by setting DSTS.RSS to '0'.
8	0h RO	SSS: Save State Status: This bit is similar to the USBSTS.SSS in host mode. When the controller has finished the save process, it will complete the command by setting DSTS.SSS to '0'

19.6.11 PAGESIZE—Offset 28h

Page Size Register Bit Definitions. This register is used by software to enable or disable the reporting of the reception of specific USB Device Notification Transaction Packets. A Notification Enable (Nx, where x = 0 to 15) flag is defined for each of the 16 possible device notification types. If a flag is set for a specific notification type, a Device Notification Event shall be generated when the respective notification packet is received. After reset all notifications are disabled. Refer to section 6.4.2.7. This register shall be written as a Dword. Byte writes produce undefined results.

19.6.13 CRCR_LO—Offset 38h

Register CRCR_LO

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CRCR LO: [BAR] + 38h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:22, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0	
0	0	0	0	0	0	0	0	0	
CMD_RING_PNTR									
RSVD14									
CRR									
CA									
CS									
RCS									

Bit Range	Default & Access	Description
31:6	0h RW	CMD_RING_PNTR: Command Ring Pointer - RW. Default = 0. This field defines high order bits of the initial value of the 64-bit Command Ring Dequeue Pointer. Writes to this field are ignored when Command Ring Running (CRR) = 1. If the CRCR is written while the Command Ring is stopped (CCR = 0), the value of this field shall be used to fetch the first Command TRB the next time the Host Controller Doorbell register is written with the DB Reason field set to Host Controller Command. If the CRCR is not written while the Command Ring is stopped (CCR = 0) then the Command Ring shall begin fetching Command TRBs at the current value of the internal xHC Command Ring Dequeue Pointer. Reading this field always returns 0.
5:4	0h RO	RSVD14: reserved

Bit Range	Default & Access	Description
3	0h RW	CRR: Command Ring Running (CRR) - RO. Default = 0. This flag is set to 1 if the Run/Stop (R/S) bit is 1 and the Host Controller Doorbell register is written with the DB Reason field set to Host Controller Command. It is cleared to 0 when the Command Ring is stopped after writing a 1 to the Command Stop (CS) or Command Abort (CA) flags, or if the R/S bit is cleared to 0.
2	0h RW	CA: Command Abort (CA) - RW1S. Default = 0. Writing a 1 to this bit shall immediately terminate the currently executing command, stop the Command Ring, and generate a Command Completion Event with the Completion Code set to Command Ring Stopped. Refer to section 4.6.1.2 for more information on aborting a command. The next write to the Host Controller Doorbell with DB Reason field set to Host Controller Command shall restart the Command Ring operation. Writes to this flag are ignored by the xHC if Command Ring Running (CRR) = 0. Reading this bit always returns 0.
1	0h RW	CS: Command Stop (CS) - RW1S. Default = 0. Writing a 1 to this bit shall stop the operation of the Command Ring after the completion of the currently executing command, and generate a Command Completion Event with the Completion Code set to Command Ring Stopped and the Command TRB Pointer set to the current value of the Command Ring Dequeue Pointer. Refer to section 4.6.1.1 for more information on stopping a command. The next write to the Host Controller Doorbell with DB Reason field set to Host Controller Command shall restart the Command Ring operation. Writes to this flag are ignored by the xHC if Command Ring Running (CRR) = 0. Reading this bit shall always return 0.
0	0h RW	RCS: Ring Cycle State (RCS) - RW. This bit identifies the value of the xHC Consumer Cycle State (CCS) flag for the TRB referenced by the Command Ring Pointer. Refer to section 4.9.3 for more information. Writes to this flag are ignored if Command Ring Running (CRR) is 1. If the CRCR is written while the Command Ring is stopped (CRR = 0), then the value of this flag shall be used to fetch the first Command TRB the next time the Host Controller Doorbell register is written with the DB Reason field set to Host Controller Command. If the CRCR is not written while the Command Ring is stopped (CRR = 0), then the Command Ring shall begin fetching Command TRBs using the current value of the internal Command Ring CCS flag. Reading this flag always returns 0.

DEVICE_CONTEXT_BAAP								

Bit Range	Default & Access	Description
31	0h RW	WPR: Warm Port Reset (WPR) RW1S/RsvdZ. Default = 0. When software writes a 1 to this bit, the Warm Reset sequence as defined in the USB3 Specification is initiated and the PR flag is set to 1. Once initiated, the PR, PRC, and WRC flags shall reflect the progress of the Warm Reset sequence. This flag shall always return 0 when read. Refer to section 4.19.5.1. of XHCI specification. This flag only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.
30	0h RW	DR: Device Removable (DR) - RO. This flag indicates if this port has a removable device attached. 1 = Device is non-removable. 0 = Device is removable.
29:28	0h RO	RSVD20: reserved
27	0h RW	WOE: Wake on Over-current Enable (WOE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to over-current conditions as system wake-up events. Refer to section 4.15 for operational model.
26	0h RW	WDE: Wake on Disconnect Enable (WDE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to device disconnects as system wake-up events. Refer to section 4.15 for operational model.
25	0h RW	WCE: Wake on Connect Enable (WCE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to device connects as system wake-up events. Refer to section 4.15 for operational model.
24	0h RO	RSVD19: reserved
23	0h RW	CEC: Port Config Error Change (CEC) RW1CS/RsvdZ. Default = 0. This flag indicates that the port failed to configure its link partner. 0 = No change. 1 = Port Config Error detected. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.2 for more information on change bit usage. Note: This flag is valid only for USB3 protocol ports. For USB2 protocol ports this bit shall be RsvdZ.
22	0h RW	PLC: Port Link State Change (PLC) RW1CS. Default = 0. This flag is set to 1 due to the following PLS transitions mentioned in the XHCI specification
21	0h RW	PRC: Port Reset Change (PRC) RW1CS. Default = 0. This flag is set to 1 due to a '1' to '0' transition of Port Reset (PR). e.g. when any reset processing (Warm or Hot) on this port is complete. Note that this flag shall not be set to 1 if the reset processing was forced to terminate due to software clearing PP or PED to '0'. 0 = No change. 1 = Reset complete. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5. Refer to section 4.19.2 for more information on change bit usage.
20	0h RW	OCC: Over-current Change (OCC) RW1CS. Default = 0. This bit shall be set to a 1 when there is a 0 to 1 or 1 to 0 transition of Over-current Active (OCA). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.
19	0h RW	WRC: Warm Port Reset Change (WRC) RW1CS/RsvdZ. Default = 0. This bit is set when Warm Reset processing on this port completes. 0 = No change. 1 = Warm Reset complete. Note that this flag shall not be set to 1 if the Warm Reset processing was forced to terminate due to software clearing PP or PED to '0'. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5.1. Refer to section 4.19.2 for more information on change bit usage. This bit only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.
18	0h RW	PEC: Port Enabled/Disabled Change (PEC) RW1CS. Default = 0. 1 = change in PED. 0 = No change. Note that this flag shall not be set if the PED transition was due to software setting PP to 0. Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage. For a USB2 protocol port, this bit shall be set to 1 only when the port is disabled due to the appropriate conditions existing at the EOF2 point (refer to section 11.8.1 of the USB2 Specification for the definition of a Port Error). For a USB3 protocol port, this bit shall never be set to 1.

Bit Range	Default & Access	Description
17	0h RW	CSC: Connect Status Change (CSC) RW1CS. Default = 0. 1 = Change in CCS. 0 = No change. This flag indicates a change has occurred in the ports Current Connect Status (CCS) or Cold Attach Status (CAS) bits. Note that this flag shall not be set if the CCS transition was due to software setting PP to 0, or the CAS transition was due to software setting WPR to 1. The xHC sets this bit to 1 for all changes to the port device connect status, even if system software has not cleared an existing Connect Status Change. For example, the insertion status changes twice before system software has cleared the changed condition, root hub hardware will be setting an already-set bit (i.e., the bit will remain 1). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.
16	0h RW	LWS: Port Link State Write Strobe (LWS) RW. Default = 0. When this bit is set to 1 on a write reference to this register, this flag enables writes to the PLS field. When 0, write data in PLS field is ignored. Reads to this bit return 0.
15:14	0h RW	PIC: Port Indicator Control (PIC) RWS. Default = 0. Writing to these bits has no effect if the Port Indicators (PIND) bit in the HCCPARAMS register is a 0.
13:10	0h RW	PORTSPEED: Port Speed (Port Speed) ROS. Default = 0. This field identifies the speed of the connected USB Device. This field is only relevant if a device is connected (CCS = 1) in all other cases this field shall indicate Undefined Speed. (more information in the XHCI specification)
9	1h RW	PP: Port Power (PP) RWS. Default = 1. This flag reflects a port's logical, power control state. Because host controllers can implement different methods of port power switching, this flag may or may not represent whether (VBus) power is actually applied to the port. When PP equals a '0' the port is nonfunctional and shall not report attaches, detaches, or Port Link State (PLS) changes. However, the port shall report over-current conditions when PP = 0 if PPC = 0. After modifying PP, software shall read PP and confirm that it is reached its target state before modifying it again, undefined behavior may occur if this procedure is not followed. 0 = This port is in the Powered-off state. 1 = This port is not in the Powered-off state. If the Port Power Control (PPC) flag in the HCCPARAMS register is '1', then xHC has port power control switches and this bit represents the current setting of the switch ('0' = off, '1' = on). If the Port Power Control (PPC) flag in the HCCPARAMS register is '0', then xHC does not have port power control switches and each port is hard wired to power, and not affected by this bit. When an over-current condition is detected on a powered port, the xHC shall transition the PP bit in each affected port from a 1 to 0 (removing power from the port). Note: If this is an SSIC Port, then the DSP Disconnect process is initiated by '1' to '0' transition of PP. Refer to section 5.1.2 in the SSIC Spec for more information. Refer to section 4.19.4 for more information.
8:5	5h RW	PLS: Port Link State (PLS) RWS. Default = RxDetect (5). This field is used to power manage the port and reflects its current link state. When the port is in the Enabled state, system software may set the link U state by writing this field. System software may also write this field to force a Disabled to Disconnected state transition of the port.
4	0h RW	PR: Port Reset (PR) RW1S. Default = 0. 1 = Port Reset signaling is asserted. 0 = Port is not in Reset. When software writes a 1 to this bit generating a 0 to 1 transition, the bus reset sequence is initiated; USB2 protocol ports shall execute the bus reset sequence as defined in the USB2 Spec. USB3 protocol ports shall execute the Hot Reset sequence as defined in the USB3 Spec. PR remains set until reset signaling is completed by the root hub. Note that software shall write a 1 to this flag to transition a USB2 port from the Polling state to the Enabled state. Refer to sections 4.15.2.3 and 4.19.1.1. This flag is 0 if PP is 0.
3	0h RW	OCA: Over-current Active (OCA) RO. Default = 0. 1 = This port currently has an over-current condition. 0 = This port does not have an over-current condition. This bit shall automatically transition from a 1 to a 0 when the over-current condition is removed.
2	0h RO	RSVD18: reserved

Bit Range	Default & Access	Description
1	0h RW	PED: Port Enabled/Disabled (PED) RW1CS. Default = 0. 1 = Enabled. 0 = Disabled. Ports may only be enabled by the xHC. Software cannot enable a port by writing a 1 to this flag. A port may be disabled by software writing a 1 to this flag. This flag shall automatically be cleared to 0 by a disconnect event or other fault condition. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller or bus events. When the port is disabled (PED = 0) downstream propagation of data is blocked on this port, except for reset. For USB2 protocol ports: When the port is in the Disabled state, software shall reset the port (PR = 1) to transition PED to 1 and the port to the Enabled state. For USB3 protocol ports: When the port is in the Polling state (after detecting an attach), the port shall automatically transition to the Enabled state and set PED to 1 upon the completion of successful link training. When the port is in the Disabled state, software shall write a 5 (RxDetect) to the PLS field to transition the port to the Disconnected state. Refer to section 4.19.1.2. PED shall automatically be cleared to 0 when PR is set to 1, and set to 1 when PR transitions from 1 to 0 after a successful reset. Refer to Port Reset (PR) bit for more information on how the PED bit is managed. Note that when software writes this bit to a 1, it shall also write a 0 to the PR bit. This flag is 0 if PP is 0.
0	0h RW	CCS: Current Connect Status (CCS) ROS. Default = 0. 1 = A device is connected to the port. 0 = A device is not connected. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change (CSC) bit to be set to 1. Refer to sections 4.19.3 and 4.19.4 for more details on the Connect Status Change (CSC) assertion conditions. This flag is 0 if PP is 0.

31:28	0h RW	PORT_TEST_CONTROL: reserved
27:16	0h RO	RSVD21: reserved
15:8	0h RW	L1DS: Reg field L1DSLOT

Bit Range	Default & Access	Description
31	0h RW	WPR: Warm Port Reset (WPR) RW1S/RsvdZ. Default = 0. When software writes a 1 to this bit, the Warm Reset sequence as defined in the USB3 Specification is initiated and the PR flag is set to 1. Once initiated, the PR, PRC, and WRC flags shall reflect the progress of the Warm Reset sequence. This flag shall always return 0 when read. Refer to section 4.19.5.1. This flag only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.
30	0h RW	DR: Device Removable (DR) - RO. This flag indicates if this port has a removable device attached. 1 = Device is non-removable. 0 = Device is removable.
29:28	0h RO	RSVD25: reserved
27	0h RW	WOE: Wake on Over-current Enable (WOE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to over-current conditions as system wake-up eventsn. Refer to section 4.15 for operational model.
26	0h RW	WDE: Wake on Disconnect Enable (WDE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to device disconnects as system wake-up eventsn. Refer to section 4.15 for operational model.
25	0h RW	WCE: Wake on Connect Enable (WCE) RWS. Default = 0. Writing this bit to a 1 enables the port to be sensitive to device connects as system wake-up events . Refer to section 4.15 for operational model.
24	0h RO	RSVD24: reserved
23	0h RW	CEC: Port Config Error Change (CEC) RW1CS/RsvdZ. Default = 0. This flag indicates that the port failed to configure its link partner. 0 = No change. 1 = Port Config Error detected. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.2 of XHCI specification for more information on change bit usage. Note: This flag is valid only for USB3 protocol ports. For USB2 protocol ports this bit shall be RsvdZ.
22	0h RW	PLC: Port Link State Change (PLC) RW1CS. Default = 0. This flag is set to 1 due to the PLS transitions in the XHCI specification
21	0h RW	PRC: Port Reset Change (PRC) RW1CS. Default = 0. This flag is set to 1 due to a '1' to '0' transition of Port Reset (PR). e.g. when any reset processing (Warm or Hot) on this port is complete. Note that this flag shall not be set to 1 if the reset processing was forced to terminate due to software clearing PP or PED to '0'. 0 = No change. 1 = Reset complete. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5. of XHCI specification. Refer to section 4.19.2 of XHCI specification. for more information on change bit usage.
20	0h RW	OCC: Over-current Change (OCC) RW1CS. Default = 0. This bit shall be set to a 1 when there is a 0 to 1 or 1 to 0 transition of Over-current Active (OCA). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.
19	0h RW	WRC: Warm Port Reset Change (WRC) RW1CS/RsvdZ. Default = 0. This bit is set when Warm Reset processing on this port completes. 0 = No change. 1 = Warm Reset complete. Note that this flag shall not be set to 1 if the Warm Reset processing was forced to terminate due to software clearing PP or PED to '0'. Software shall clear this bit by writing a '1' to it. Refer to section 4.19.5.1. Refer to section 4.19.2 for more information on change bit usage. This bit only applies to USB3 protocol ports. For USB2 protocol ports it shall be RsvdZ.
18	0h RW	PEC: Port Enabled/Disabled Change (PEC) RW1CS. Default = 0. 1 = change in PED. 0 = No change. Note that this flag shall not be set if the PED transition was due to software setting PP to 0. Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage. For a USB2 protocol port, this bit shall be set to 1 only when the port is disabled due to the appropriate conditions existing at the EOF2 point (refer to section 11.8.1 of the USB2 Specification for the definition of a Port Error). For a USB3 protocol port, this bit shall never be set to 1.

Bit Range	Default & Access	Description
17	0h RW	CSC: Connect Status Change (CSC) RW1CS. Default = 0. 1 = Change in CCS. 0 = No change. This flag indicates a change has occurred in the ports Current Connect Status (CCS) or Cold Attach Status (CAS) bits. Note that this flag shall not be set if the CCS transition was due to software setting PP to 0, or the CAS transition was due to software setting WPR to 1. The xHC sets this bit to 1 for all changes to the port device connect status, even if system software has not cleared an existing Connect Status Change. For example, the insertion status changes twice before system software has cleared the changed condition, root hub hardware will be setting an already-set bit (i.e., the bit will remain 1). Software shall clear this bit by writing a 1 to it. Refer to section 4.19.2 for more information on change bit usage.
16	0h RW	LWS: Port Link State Write Strobe (LWS) RW. Default = 0. When this bit is set to 1 on a write reference to this register, this flag enables writes to the PLS field. When 0, write data in PLS field is ignored. Reads to this bit return 0.
15:14	0h RW	PIC: Port Indicator Control (PIC) RWS. Default = 0. Writing to these bits has no effect if the Port Indicators (PIND) bit in the HCCPARAMS register is a 0
13:10	0h RW	PORTSPEED: Port Speed (Port Speed) ROS. Default = 0. This field identifies the speed of the connected USB Device. This field is only relevant if a device is connected (CCS = 1) in all other cases this field shall indicate Undefined Speed.
9	1h RW	PP: Port Power (PP) RWS. Default = 1. This flag reflects a port's logical, power control state. Because host controllers can implement different methods of port power switching, this flag may or may not represent whether (VBus) power is actually applied to the port. When PP equals a '0' the port is nonfunctional and shall not report attaches, detaches, or Port Link State (PLS) changes. However, the port shall report over-current conditions when PP = 0 if PPC = 0. After modifying PP, software shall read PP and confirm that it is reached its target state before modifying it again, undefined behavior may occur if this procedure is not followed. 0 = This port is in the Powered-off state. 1 = This port is not in the Powered-off state. If the Port Power Control (PPC) flag in the HCCPARAMS register is '1', then xHC has port power control switches and this bit represents the current setting of the switch ('0' = off, '1' = on). If the Port Power Control (PPC) flag in the HCCPARAMS register is '0', then xHC does not have port power control switches and each port is hard wired to power, and not affected by this bit. When an over-current condition is detected on a powered port, the xHC shall transition the PP bit in each affected port from a 1 to 0 (removing power from the port). Note: If this is an SSIC Port, then the DSP Disconnect process is initiated by '1' to '0' transition of PP. Refer to section 5.1.2 in the SSIC Spec for more information. Refer to section 4.19.4 for more information.
8:5	5h RW	PLS: Port Link State (PLS) RWS. Default = RxDetect (5). This field is used to power manage the port and reflects its current link state. When the port is in the Enabled state, system software may set the link U state by writing this field. System software may also write this field to force a Disabled to Disconnected state transition of the port.
4	0h RW	PR: Port Reset (PR) RW1S. Default = 0. 1 = Port Reset signaling is asserted. 0 = Port is not in Reset. When software writes a 1 to this bit generating a 0 to 1 transition, the bus reset sequence is initiated; USB2 protocol ports shall execute the bus reset sequence as defined in the USB2 Spec. USB3 protocol ports shall execute the Hot Reset sequence as defined in the USB3 Spec. PR remains set until reset signaling is completed by the root hub. Note that software shall write a 1 to this flag to transition a USB2 port from the Polling state to the Enabled state. Refer to sections 4.15.2.3 and 4.19.1.1. of XHCI specification. This flag is 0 if PP is 0.
3	0h RW	OCA: Over-current Active (OCA) RO. Default = 0. 1 = This port currently has an over-current condition. 0 = This port does not have an over-current condition. This bit shall automatically transition from a 1 to a 0 when the over-current condition is removed.

Bit Range	Default & Access	Description
31:30	0h RO	GRXTHRCFG_RSVD3: Reserved
29	1h RW	USBRXPCTCNTSEL: USB ReceivePacket Count Enable: This field enables/disables the USB reception multi-packet thresholding: n 0: The core can only start reception on the USB when the RX FIFO has space for at least one packet. n 1: The core can only start reception on the USB when the RX FIFO has space for at least USBRxPktCnt amount of packets. This mode is only valid in the host mode. It is only used for SuperSpeed.
28	0h RO	GRXTHRCFG_RSVD2: Reserved
27:24	2h RW	USBRXPCTCNT: USB Receive Packet Count: This field specifies space (in number of packets) that must be available in the RX FIFO before the core can start the corresponding USB RX transaction (burst). This field is only valid when the USB Receive Packet Count Enable field is set to one. The valid values are from 1 to 15.
23:19	10h RW	USBMAXRXBURSTSIZE: USB Maximum Receive Burst Size: This field is only valid when USBRxPktCntSel is one. This field specifies the Maximum Bulk IN burst the core should do. When the system bus is slower than the USB, RX FIFO can overrun during a long burst. User can program a smaller value to this field to limit the RX burst size that the core can do. It only applies to SS Bulk, Isochronous, and Interrupt IN endpoints in the host mode. Valid values are from 1 to 16.
18:0	0h RO	GRXTHRCFG_RSVD1: Reserved

19.6.63 GCTL—Offset C110h

Global Common Register

Access Method

Type: Memory Mapped I/O Register

Bit Range	Default & Access	Description
31:19	08b0h RW	PWRDNSCALE: Reg field PWRDNSCALE
18	0h RW	MASTERFILTBYPASS: Master Filter Bypass: When this bit is set to 1'b1, irrespective of the parameter DWC_USB3_EN_BUS_FILTERS chosen, all the filters in the DWC_usb3_filter module will be bypassed. The double synchronizers to mac_clk preceding the filters will also be bypassed. For enabling the filters, this bit should be 1'b0.
17	0h RW	BYPSETADDRINDEVMODE:
16	0h RW	U2RSTECN: If the super speed connection fails during POLL or LMP exchange, the device connects at non-SS mode. If this bit is set, then device attempts three more times to connect at SS, even if it previously failed to operate in SS mode.
15:14	0h RW	FRMSCLDWN: This field scales down device view of a SOF/USOF/ITP duration. For SS/HS mode: Value of 2'h3 implements interval to be 15. 625 us Value of 2'h2 implements interval to be 31.25 us Value of 2'h1 implements interval to be 62.5 us Value of 2'h0 implements interval to be 125us For FS mode, the scale-down value is multiplied by 8.
13:12	3h RW	PRTCAPDIR: Reg field PRTCAPDIR
11	0h RW	CORESOFTRST: Core Soft Reset (CoreSoftReset) 1b0 - No soft reset 1b1 - Soft reset to core When you reset PHYs (using GUBS3PHYCFG or GUSB3PIPECTL registers), you must keep the core in reset state until PHY clocks are stable. This controls the bus, ram, and mac domain resets.
10	0h RW	SOFITPSYNC: Sync ITP to reference clock
9	0h RO	GCTL_RSVD2: Disable U1/U2 timer Scaledown (U1U2TimerScale) If set to '1' along with GCTL[5:4] (ScaleDown) = 2'bX1 disables the scale down of U1/U2 inactive timer values. This is for simulation mode only.
8	0h RW	DEBUGATTACH: Debug Attach
7:6	0h RW	RAMCLKSEL: Reg field RAMCLKSEL
5:4	0h RW	SCALEDOWN: reg field SCALEDOWN
3	0h RW	DISSCRAMBLE: Disable Scrambling
2	0h RO	GCTL_RSVD1: Reserved

Bit Range	Default & Access	Description
1	0h RW	GBLHIBERNATIONEN: This bit enables hibernation at the global level. If hibernation is not enabled via this bit, the PMU immediately accepts the D0-)D3 and D3-)D0 power state change requests, but does not save or restore any core state. In addition, the PMUs will never drive the PHY interfaces and let the core continue to drive the PHY interfaces.
0	0h RW	DSBLCLKGTNG: Disable Clock Gating

MAC3FLADJ NOEXTRDL PSQEXTRESSP SPRSCTRLTRANSEN RESBWHSEPS CMDEVADDR USBHSTINAUTORETRYEN GUCTL_RSVD1 DTCT DTFT								

Bit Range	Default & Access	Description
31:22	1ffh RW	MAC3FLADJ:
21	0h RW	NOEXTRDL:
20:18	0h RW	PSQEXTRRESSP:
17	0h RW	SPRSCTRLTRANSEN: Sparse Control Transaction Enable: Some devices are slow in responding to Control transfers. Scheduling multiple transactions in one microframe/frame can cause these devices to misbehave. If this bit is set to 1'b1, the host controller schedules transactions for a Control transfer in different microframes/frames.
16	0h RW	RESBWHSEPS: Reserving 85% Bandwidth for HS Periodic EPs
15	1h RW	CMDEVADDR: Compliance Mode for Device Address: When this bit is 1'b1, Slot ID may have different value than Device Address if max_slot_enabled (128. n 1'b1: Increment Device Address on each Address Device command. n 1'b0: Device Address is equal to Slot ID. The xHCI compliance requires this bit to be set to 1'. The 0' mode is for debug purpose only. This all ows you to easily identify a device connected to a port in the Lecroy or Eliisys trace during hardware debug. This bit is valid in Host and DRD configuration and is used in host mode operation only. Ignore this bit in device mode.
14	1h RW	USBHSTINAUTORETRYEN: Host IN Auto Retry: When set, this field enables the Auto Retry feature. For IN transfers (non-isochronous) that encounter data packets with CRC errors or internal overrun scenarios, the auto retry feature causes the Host core to reply to the device with a non-terminating retry ACK (that is, an ACK transaction packet with Retry = 1 and NumP != 0). If the Auto Retry feature is disabled (default), the core will respond with a terminating retry ACK (that is, an ACK transaction packet with Retry = 1 and NumP = 0). n 1'b0: Auto Retry Disabled n 1'b1: Auto Retry Enabled In device mode this bit should be 0
13:11	0h RO	GUCTL_RSVD1:
10:9	3h RW	DTCT: Device Timeout Coarse Tuning: This field is a Host mode parameter which determines how long the host waits for a response from device before considering a timeout. The core first checks the DTCT value. If it is 0, then the timeout value is defined by the DTFT. If it is non-zero, then it uses the following timeout values: n 2'b00: 0 usec -) use DTFT value instead n 2'b01: 500 usec n 2'b10: 1.5 msec n 2'b11: 6.5 msec
8:0	0h RW	DTFT: Device Timeout Fine Tuning: This field is a Host mode parameter which determines how long the host waits for a response from device before considering a timeout. For DTFT field to take effect, DTCT must be set to 2'b00. The DTFT value is the number of 125 MHz clocks * 256 to count before considering a device timeout. For the 125 MHz clk (8 ns period), this is calculated as follows: (DTFT value) * 256 * (8 ns) Quick Reference: n if DTFT = 0x2, 2*256*8 = 4usec timeout n if DTFT = 0x5, 5*256*8 = 10usec timeout n if DTFT = 0xA, 10*256*8 = 20usec timeout n if DTFT = 0x10, 16*256*8 = 32usec timeout n if DTFT = 0x19, 25*256*8 = 51usec timeout n if DTFT = 0x31, 49*256*8 = 100usec timeout n if DTFT = 0x62, 98*256*8 = 200usec timeout

Bit Range	Default & Access	Description
31	0h RW	PHYSOFTIRST: Reg field PHYSOFTIRST
30:28	0h RO	GUSB3PIPECTL_RSVD2:
27	0h RW	UX_EXIT_IN_PX: Ux Exit in Px: n 0: The core does U1/U2/U3 exit in PHY power state P0 (default behavior) n 1: The core does U1/U2/U3 exit in PHY power state P1/P2/P3 respectively This bit is added for SS PHY workaround where SS PHY injects a glitch on pipe3_RxElecIdle while receiving Ux exit LFPS, and pipe3_PowerDown change is in progress. Note: This bit is used by third-party SS PHY. It should be set to '0' for Synopsys PHY.
26	0h RW	PING_ENHANCEMENT_EN: Ping Enhancement Enable: When set, the Downstream port U1 ping receive timeout becomes 500 ms instead of 300 ms. Minimum Ping.LFPS receive duration is 8 ns (one mac3_clk). This field is valid for Downstream port only. Note: This bit is used by third-party SS PHY. It should be set to '0' for Synopsys PHY.
25	1h RW	U1U2EXITFAIL_TO_RECOV: Reg field u1u2exitfail_to_recov
24	0h RW	REQUESTp1p2p3 (RequestP1P2P3):
23	0h RW	STARTRXDETU3RXDET (StartRxDetU3RxDet): Reg field StartRxDetU3RxDet
22	0h RW	DISRXDETU3RXDET (DisRxDetU3RxDet): Disable Receiver Detection in U3/Rx.Det: When set, the core does not do receiver detection in U3 or Rx.Detect state. DWC_USB3_GUSB3PIPECTL_INIT[23] should be used to start receiver detection manually. This bit is valid for Downstream ports only. Delay P1P2P3 Delay P0 to P1/P2/P3 request when entering U1/U2/U3 until (DWC_USB3_GUSB3PIPECTL_INIT[21:19]*8) 8B10B error occurs, or Pipe3_RxValid drops to 0. DWC_USB3_GUSB3PIPECTL_INIT[18] must be 1 to enable this functionality. Delay PHY power change from P0 to P1/P2/P3 when link state changing from U0 to U1/U2/U3 respectively. n 1'b1: When entering U1/U2/U3, delay the transition to P1/P2/P3 until the pipe3 signals, Pipe3_RxElecIdle is 1 and pipe3_RxValid is 0 n 1'b0: When entering U1/U2/U3, transition to P1/P2/P3 without checking for Pipe3_RxElecIdle and pipe3_RxValid. Note: This bit should be set to '1' for Synopsys PHY. It is also used by third-party SS PHY.

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:22, F:0] + 10h

Default: 80000000h

Bit Range	Default & Access	Description
31	1h RO	DeviceMode: Device Mode: Indicates whether the device is in A-device or B-device mode based on utmiotg_idddig n 1'b0: A-Device mode n1'b1: B-Device mode The rest of the OTG Event Information bits (OTGxxxxEvtInfo) in OEVT register will be based on the contents of this field.

Bit Range	Default & Access	Description
30:25	0h RO	RSVD0: reserved
24	0h RO	OTGConIDStsChngEvnt: Write Behavior: oneToClear Connector ID Status Change Event: Set in both A-Dev/B-Dev Mode. This event is generated when there is a change in connector ID status.
23:21	0h RO	RSVD1: reserved
20	0h RO	OTGADevBHostEndEvnt: Write Behavior: oneToClear A-device B-Host End Event: Set in A-device Mode Only. The event is generated when B-device has completed its host role. Note: This bit is applicable for OTG 2.0 and OTG 3.0 modes of operation.
19	0h RO	OTGADevHostEvnt: Write Behavior: oneToClear A-device host event: Set in A-device Mode Only. This event is generated when A-device enters host role. In HS/FS mode, it occurs after the initial connect to a B-device as A-host as well as when there is a role change from A-peripheral to A-host. Note: This bit is applicable only for OTG 2.0 mode of operation.
18	0h RO	OTGADevHNPChngEvnt: Write Behavior: oneToClear A-Dev HNP Change Event: Set in A-device Mode Only. The event is generated when there is an HNP attempt. Note: This bit is applicable only for OTG 2.0 mode of operation.
17	0h RO	OTGADevSRPDetEvnt: Write Behavior: oneToClear SRP Detect Event: Set in A-device Mode Only. This event is asserted when a session request from the B-device is detected via SRP. Note: This bit is applicable for OTG 2.0 and OTG 3.0 modes of operation.
16	0h RO	OTGADevSessEndDetEvnt: Write Behavior: oneToClear Session End Detected Event: Set in A-device Mode Only. This event is asserted when the utmisrp_avalid signal goes low indicating the end of a session. Note: This bit is applicable for OTG 2.0 and OTG 3.0 modes of operation
15:12	0h RO	RSVD2: Reserved
11	0h RO	OTGBDevBHostEndEvnt: Write Behavior: oneToClear B-Device B-Host End Event: Set in B-device Mode Only. This event is generated when B-device has completed its host role. Note: This bit is applicable for OTG 2.0 and OTG 3.0 modes of operation.
10	0h RO	OTGBDevHNPChngEvnt: Write Behavior: oneToClear B-Dev HNP Change Event: Set in B-Device Mode only. This event is generated when there is a Success or Failure of an HNP attempt. Note: This bit is applicable for OTG 2.0 and OTG 3.0 modes of operation.
9	0h RO	OTGBDevSessVldDetEvnt: Write Behavior: oneToClear Session Valid Detected Event: Set in B-device Mode Only. This event is asserted when there is a valid Vbus from A-device and B-device succeeds in starting a session. Note: This bit is applicable for OTG 2.0 and OTG 3.0 modes of operation.
8	0h RO	OTGBDevVBUSChngEvnt: Write Behavior: oneToClear Vbus Change Event: Set in B-device Mode Only. This event is asserted when the utmisrp_bvalid signal goes low (indicating the end of a session), or goes high. Note: This bit is applicable for OTG 2.0 and OTG 3.0 modes of operation.
7:4	0h RO	RSVD3: reserved
3	0h RO	BSesVld: Indicates the Device mode transceiver status. Indicates the Device mode transceiver status. The core updates this bit when OEVTEN.OTGBDevVBUSChngEvnt is set. 1b0: B-session is not valid 1b1: B-session is valid Note: This bit is applicable for OTG 2.0 and OTG 3.0 modes of operation.
2	0h RO	HstNegSts: Host Negotiation Status: The core updates this bit when any of the following bits is set: n OEVTEN.OTGADevHNPChngEvnt n OEVTEN.OTGBDevHNPChngEvnt This bit indicates Host Negotiation Success or Failure. n 1'b0: Host negotiation failure. In A-device, for HS/FS, this indicates an imminent end of session indication from the core. In B-device, for HS/LS, it indicates that the timer used to wait for an A-device to signal a connection (b_ase0_brst_tmout in OTG 2.0) timed out resulting in B-device staying as B-peripheral. n 1'b1: Host negotiation success. This indicates that the host negotiation was successful. Note: This bit is applicable only for OTG 2.0 mode of operation.

Bit Range	Default & Access	Description
1	0h RO	SesReqSts: Session Request Status: The core updates this bit when OEVTEN.OTGBDevSessVldDetEvnt is set. o 1'b0: Session request due to Vbus. This indicates that the session started due to Vbus without SRP detection by A-host. o 1'b1: Session request due to SRP. This indicates that the session started as a result of successful SRP detection by A-host. Note: This bit is applicable for OTG 2.0 and OTG 3.0 modes of operation.
0	0h RO	OEVTError: Write Behavior: oneToClear OTG Event Error: There are no errors currently defined.

20 Intel® High Definition Audio

The Intel® High Definition Audio (Intel® HD Audio) is an architecture and infrastructure to support high-quality audio implementations for PCs.

Note: The High Definition Audio interface is multiplexed on the same balls as LPE_I2S[1:0].

Note: When High Definition Audio is active, the LPE Audio functionality is disabled.

The Intel® High Definition Audio (Intel® HD Audio) controller consists of a set of DMA engines that are used to move samples of digitally encoded data between system memory and internal/external CODECs. The controller communicates with the internal/external CODECs over the Intel® HD Audio serial link. The output DMA engines move digital data from system memory to a D-A converter in a CODEC. The SoC implements a single Serial Data Output (SDO) signal that is connected to the external CODECs. The input DMA engines move digital data from the A-D converter in the CODEC to system memory. The platform supports up to two external CODECs by implementing two Serial Data Input (SDI) signals, each being dedicated to a single CODEC.

Audio software renders outbound, and processes inbound data to/from buffers in memory. The location of the individual buffers is described by a Buffer Descriptor List that is fetched and processed by the audio controller. The data in the buffers is arranged in a pre-defined format. The output DMA engines fetch the digital data from memory and reformat it based on the programmed sample rate, bits/sample and number of channels. The data from the output DMA engines is then combined and serially sent to the CODEC(s) over the Intel® HD Audio link. The input DMA engines receive data from the CODEC(s) over the Intel® HD Audio link and format the data based on the programmable attributes for that stream. The data is then written to memory in the predefined format for software to process. Each DMA engine moves one "stream" of data. A single CODEC can accept or generate multiple "streams" of data, one for each A-D or D-A converter in the CODEC. Multiple CODECs can accept the same output "stream" processed by a single DMA engine.

Codec commands and responses are also transported to and from the CODEC via DMA engines. The DMA engine dedicated to transporting commands from the Command Output Ring Buffer (CORB) in memory to the CODEC(s) is called the CORB engine. The DMA engine dedicated to transporting responses from the CODEC(s) to the Response Input Ring Buffer in memory is called the RIRB engine. Every command sent to a CODEC yields a response from that CODEC. Some commands are “broadcast” type commands in which case a response will be generated from each CODEC. A CODEC may also be programmed to generate unsolicited responses, which the RIRB engine also processes. The platform also supports Programmed IO-based Immediate Command/Response transport mechanism that can be used by BIOS prior to memory initialization.

20.1 Signal Descriptions

Please see [Chapter 2, “Physical Interfaces”](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal’s function

Table 223. Signals

Signal Name	Direction Plat. Power	Description
HDA_RST#	O VAUD	Intel HD Audio Reset: Master H/W reset to external Codecs
HDA_SYNC	O VAUD	Intel HD Audio Sync: 48 kHz fixed rate
HDA_CLK	O VAUD	Intel HD Audio Bit Clock (Output): 24 MHz serial data clock generated by the Intel HD Audio controller
HDA_SDO	O VAUD	Intel HD Audio Data Out: Serial TDM data output to the Codec(s). The serial output is double-pumped for a bit rate of 48 Mb/s
HDA_SDI[1:0]	I/O VAUD	Intel HD Audio Serial Data In[1:0]: Serial TDM data input from the CODEC(s). The serial input is single-pumped for a bit rate of 24 Mb/s.
HDA_LPE_RCOMP	O	Impedance/ current Compensation Output.

The signals in the table above are all muxed and maybe used by other functions.

20.2 Features

The Intel® HD Audio Controller supports the following features:

- Supports MSI and legacy interrupt delivery
- Support for ACPI D3 and D0 Device States
- Supports up to:
 - 6 streams (three input, three output)
 - 16 channels per stream
 - 32 bits/sample
 - 192 kHz sample rate
- 24 MHz HDA_CLK supports
 - SDO double pumped at 48 Mb/s
 - SDI single pumped at 24 Mb/s
- Supports 1.5V mode only
- Supports optional Immediate Command/Response mechanism

20.3 References

High Definition Audio Specification, Revision 1.0a

20.4 Register Map

See Chapters 3 and 4 for additional information.

Note: PCI mode is supported, but not PCIe mode. Must set TM1.HAPD bit to 1b for PCI mode.

7:0	0h RO	PI: Programming Interface

20.5.7 SCC—Offset Ah

Sub Class Code

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

SCC: [B:0, D:27, F:0] + Ah

Default: 03h

7				4					0
0	0	0	0	0	0	0	1	1	
SCC									

Bit Range	Default & Access	Description
7:0	03h RO	SCC: Sub Class Code

20.5.8 BCC—Offset Bh

Base Class Code

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

BCC: [B:0, D:27, F:0] + Bh

Default: 04h

7				4					0
0	0	0	0	0	0	1	0	0	
BCC									

Bit Range	Default & Access	Description
7:0	04h RO	BCC: Base Class Code

20.5.9 CLS—Offset Ch

Cache line size

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

CLS: [B:0, D:27, F:0] + Ch

Default: 00h

7				4					0
0	0	0	0	0	0	0	0	0	
CLS									

Bit Range	Default & Access	Description
7:0	0h RW	CLS: Cache line size

20.5.10 LT—Offset Dh

Latency timer

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

LT: [B:0, D:27, F:0] + Dh

Default: 00h

7	4	0
0	0	0
LT		

Bit Range	Default & Access	Description
7:0	0h RO	LT: Latency timer

20.5.11 HTYPE—Offset Eh

Header type

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

HTYPE: [B:0, D:27, F:0] + Eh

Default: 00h

7	4	0
0	0	0
HTYPE		

Bit Range	Default & Access	Description
7:0	0h RO	HTYPE: Header type

20.5.12 BIST—Offset Fh

Built in self test. Not implemented.

Access Method

Type: PCI Configuration Register
(Size: 8 bits)

BIST: [B:0, D:27, F:0] + Fh

Default: 00h

7	4	0
0	0	0
BIST		

20.5.15 SVID—Offset 2Ch

subsystem vendor ID

Access Method

Type: PCI Configuration Register
(Size: 16 bits)

SVID: [B:0, D:27, F:0] + 2Ch

Default: 0000h

15				12					8					4					0

PMES	D2S	D1S	AC	DSI
				Reserved
				PMEC
				VS

Bit Range	Default & Access	Description
15:11	19h RO	PMES: PME_Support (PMES): Indicates PME# can be generated from D3 and D0 states.
10	0h RO	D2S: D2 state. Not supported.
9	0h RO	D1S: D1 state. Not supported.
8:6	1h RO	AC: Aux Current
5	0h RO	DSI: Device specific initialization
4	0h RO	Reserved: Reserved
3	0h RO	PMEC: PME Clock. Does not apply.
2:0	2h RO	VS: Version (VS): Indicates support for Revision 1.1 of the PCI Power Management Specification.

20.5.27 PCS—Offset 54h

Power Management control and status

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

PCS: [B:0, D:27, F:0] + 54h

Default: 00000000h

31				28				24				20				16				12				8				4				0																			
0				0				0				0				0				0				0				0				0																			
DT								BPCCE				B23				Reserved_0								PMES				Reserved_1								PMEE				Reserved_2								PS			

Bit Range	Default & Access	Description
31:24	0h RO	DT: Data. Does not apply.
23	0h RO	BPCCE: Bus power control enable. Does not apply.
22	0h RO	B23: Does not apply.
21:16	0h RO	Reserved_0: Reserved
15	0h RW1C	PMES: PME Status (PMES): This bit is set when the Intel HD Audio controller would normally assert the PME# signal independent of the state of the PME_En bit. This bit resides in the Suspend well. This bit is in the Suspend well and cleared on a power-on reset. Software must not make assumptions about the reset state of this bit and must set it appropriately.
14:9	0h RO	Reserved_1: Reserved
8	0h RW	PMEE: PME enable
7:2	0h RO	Reserved_2: reserved
1:0	0h RW	PS: Power State (PS): This field is used both to determine the current power state of the Intel HD Audio controller and to set a new power state. The values are: 00 D0 state 11 D3HOT state If software attempts to write a value of 10b or 01b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, the Intel HD Audio controllers configuration space is available, but the I/O and memory spaces are not. Additionally, interrupts are blocked. When software changes this value from the D3HOT state to the D0 state, an internal warm (soft) reset is generated, and software must re-initialize the function.

20.5.28 MID—Offset 60h

MSI Capability ID

Access Method

Type: PCI Configuration Register
(Size: 16 bits)

MID: [B:0, D:27, F:0] + 60h

Bit Range	Default & Access	Description
0	01h RW	BIT_ADDRESS_SUPPORTED: A 1 indicates that the Intel HD Audio controller supports 64 bit addressing for BDL addresses data buffer addresses and command buffer addresses.

20.6.2 VMIN—Offset 2h

Minor Version

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

VMIN: [AZLBAR] + 2h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00h

7	4	0
0	0	0
MINOR_VERSION		

Bit Range	Default & Access	Description
7:0	00h RO	MINOR_VERSION: Indicates SoC supports minor revision number 00h of the Intel HD Audio specification.

20.6.3 VMAJ—Offset 3h

Major Version

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

VMAJ: [AZLBAR] + 3h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 01h

7	4	0
0	0	1
MAJOR_VERSION		

Bit Range	Default & Access	Description
7:0	01h RO	MAJOR_VERSION: Indicates SoC supports major revision number 1 of the Intel HD Audio specification.

20.6.4 OUTPAY—Offset 4h

Output Payload Capability

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

OUTPAY: [AZLBAR] + 4h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 003Ch

15			12				8				4			0
0	0	0	0	0	0	0	0	0	0	1	1	1	1	0
OUTPUT_PAYLOAD_CAPABILITY														

Bit Range	Default & Access	Description
15:0	003Ch RO	OUTPUT_PAYLOAD_CAPABILITY: Indicates the total output payload available on the link. This does not include bandwidth used for command and control. This measurement is in 16 bit word quantities per 48 kHz frame. The default link clock speed of 24.000 MHz the data is double pumped provides 1000 bits per frame or 62.5 words in total. 40 bits are used for command and control leaving 60 words available for data payload. 00h 0 words 01h 1 word payload FFh 255h word payload

20.6.5 INPAY—Offset 6h

Bit Range	Default & Access	Description
15:0	001Dh RO	INPUT_PAYLOAD_CAPABILITY: Indicates the total input payload available on the link. This does not include bandwidth used for response. This measurement is in 16 bit word quantities per 48 kHz frame. The default link clock speed of 24.000 MHz provides 500 bits per frame or 31.25 words in total. 36 bits are used for response leaving 29 words for data payload. 00h 0 words 01h 1 word payload FFh 255h word payload

20.6.6 GCTL—Offset 8h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RESERVED0						ACCEPT_UNSOLICITED_RESPONSE_ENABLE	RESERVED1	FLUSH_CONTROL CONTROLLER_RESET

Bit Range	Default & Access	Description
31:9	0h RO	RESERVED0: reserved
8	0h RW	ACCEPT_UNSOLICITED_RESPONSE_ENABLE: If UNSOL is a 1 Unsolicited Responses from the codecs are accepted by the controller and placed into the Response Input Ring Buffer. If UNSOL is a 0 unsolicited responses are not accepted and dropped on the floor.
7:2	00h RO	RESERVED1: reserved
1	0h RW	FLUSH_CONTROL: Writing a 1 to this bit initiates a flush. When the flush completion is received by the controller hardware sets the Flush Status bit and clears this Flush Control bit. Before a flush cycle is initiated the DMA Position Buffer must be programmed with a valid memory address by software but the DMA Position Buffer bit 0 need not be set to enable the position reporting mechanism. Also all streams must be stopped the associated RUN bit must be 0 . When the flush is initiated the controller will flush pipelines to memory to guarantee that the hardware is ready to transition to a D3 state. Setting this bit is not a critical step in the power state transition if the content of the FIFOs is not critical.
0	0h RW	CONTROLLER_RESET: Writing a 0 to this bit causes the Intel HD Audio controller to be reset. All state machines FIFO s and non Suspend well memory mapped configuration registers except ECAP and PCI Configuration Registers in the controller will be reset. The Intel HD Audio link RESET signal will be asserted and all other link signals will be driven to their reset values. After the hardware has completed sequencing into the reset state it will report a 0 in this bit. Software must read a 0 from this bit to verify that the controller is in reset. Writing a 1 to this bit causes the controller to exit its reset state and de assert the Intel HD Audio link RESET signal. Software is responsible for setting clearing this bit such that the minimum Intel HD Audio link RESET signal assertion pulse width specification is met. When the controller hardware is ready to begin operation it will report a 1 in this bit. Software must read a 1 from this bit before accessing any controller registers. The CRST bit defaults to a 0 after hardware reset therefore software needs to write a 1 to this bit to begin operation. Note that the CORB RIRB RUN bits and all Stream RUN bits must be verified cleared to zero before CRST is written to 0 asserted in order to assure a clean re start. When setting or clearing CRST software must ensure that minimum link timing requirements minimum RESET assertion time etc. are met. When CRST is 0 indicating that the controller is in reset writes to all Intel HD Audio memory mapped registers are ignored as if the device is not present. The only exception is the Global Control register containing the CRST bit itself. The Global Control register is writeable as a DWord Word or Byte even when CRST is 0 if the byte enable for the byte containing the CRST bit Byte Enable 0 is active. If Byte Enable 0 is not active writes to the Global Control register will be ignored when CRST is 0. When CRST is 0 reads to Intel HD Audio memory mapped registers will return their default value except for registers that are not reset with PLTRST or on a D3hot to D0 transition.

20.6.7 WAKEEN—Offset Ch

Wake Enable

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

WAKEEN: [AZLBAR] + Ch

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00h

7	4	0
0	0	0
RESERVED0		SDIN_WAKE_ENABLE_FLAGS

Bit Range	Default & Access	Description
7:4	0h RO	RESERVED0: reserved
3:0	0h RW	SDIN_WAKE_ENABLE_FLAGS: Bits which control which SDI signal s may generate a wake event. A 1 bit in the bit mask indicates that the associated SDIN signal is enabled to generate a wake.

20.6.8 WAKESTS—Offset Eh

Wake Status

Access Method

Type: Memory Mapped I/O Register
(Size: 8 bits)

WAKESTS: [AZLBAR] + Eh

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00h

7				4					0
0	0	0	0	0	0	0	0	0	0
RESERVED0					SDIN_STATE				

Bit Range	Default & Access	Description
7:4	0h RO	RESERVED0: reserved
3:0	0h RO	SDIN_STATE: Flag bits that indicate which SDI signal s received a State Change event. The bits are cleared by writing 1 s to them.

20.6.9 GSTS—Offset 10h

Global Status

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

GSTS: [AZLBAR] + 10h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 0000h

15				12					8					4					0
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
RESERVED0																FLUSH_STATUS		RESERVED1	

Bit Range	Default & Access	Description
15:2	0000h RO	RESERVED0: reserved
1	0h RW	FLUSH_STATUS: This bit is set to a 1 by the hardware to indicate that the flush cycle initiated when the FCNTRL bit was set has completed. Software must write a 1to clear this bit before the next time FCNTRL is set.

20.6.12 INTCTL—Offset 20h

Interrupt Control

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

INTCTL: [AZLBAR] + 20h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
GLOBAL_INTERRUPT_ENABLE	RESERVED0						STREAM_INTERRUPT_ENABLE	
CONTROLLER_INTERRUPT_ENABLE								

Bit Range	Default & Access	Description
31	0h RW	GLOBAL_INTERRUPT_ENABLE: Global bit to enable device interrupt generation. When set to 1 the Intel HD Audio function is enabled to generate an interrupt. This control is in addition to any bits in the bus specific address space such as the Interrupt Enable bit in the PCI Configuration Space. This bit is not affected by controller reset.
30	0h RW	CONTROLLER_INTERRUPT_ENABLE: Enables the general interrupt for controller functions. When set to 1 and GIE is enabled the controller generates an interrupt when the CIS bit gets set. This bit is not affected by controller reset.
29:8	0h RO	RESERVED0: reserved
7:0	00h RW	STREAM_INTERRUPT_ENABLE: When set to 1 the individual Streams are enabled to generate an interrupt when the corresponding stream status bits get set. A stream interrupt will be caused as a result of a buffer with IOC 1 in the BDL entry being completed or as a result of a FIFO error underrun or overrun occurring. Control over the generation of each of these sources is in the associated Stream Descriptor. The streams are numbered and the SIE bits assigned sequentially based on their order in the register set. Bit 0 Input Stream 1 Bit 1 Input Stream 2 Bit 2 Input Stream 3 Bit 3 Input Stream 4 Bit 4 Output Stream 1 Bit 5 Output Stream 2 Bit 6 Output Stream 3 Bit 7 Output Stream 4

20.6.14 WALCLK—Offset 30h

Wall Clock Counter

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

WALCLK: [AZLBAR] + 30h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0

WALL_CLOCK_COUNTER

Bit Range	Default & Access	Description
31:0	0h RO	WALL_CLOCK_COUNTER: 32 bit counter that is incremented on each link BCLK period and rolls over from FFFF_FFFFh to 0000_0000h. This counter will roll over to zero with a period of approximately 179 seconds. This counter is enabled while the BCLK bit is set to 1. Software uses this counter to synchronize between multiple controllers. Will be reset on controller reset.

20.6.15 SSYNC—Offset 38h

Stream Synchronization

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSYNC: [AZLBAR] + 38h

RESERVED0								STREAM_SYNCHRONIZATION_BITS

Bit Range	Default & Access	Description
31:8	0h RO	RESERVED0: reserved
7:0	00h RW	STREAM_SYNCHRONIZATION_BITS: The Stream Synchronization bits when set to 1 block data from being sent on or received from the link. Each bit controls the associated Stream Descriptor bit 0 corresponds to the first Stream Descriptor etc. To synchronously start a set of DMA engines the bits in the SSYNC register are first set to a 1. The RUN bits for the associated Stream Descriptors are then set to a 1 to start the DMA engines. When all streams are ready FIFORDY 1 the associated SSYNC bits can all be set to 0 at the same time and transmission or reception of bits to or from the link will begin together at the start of the next full link frame. To synchronously stop streams first the bits are set in the SSYNC register and then the individual RUN bits in the Stream Descriptors are cleared by software. The streams are numbered and the SSYNC bits assigned sequentially based on their order in the register set. Bit 0 Input Stream 1 Bit 1 Input Stream 2 Bit 2 Input Stream 3 Bit 3 Input Stream 4 Bit 4 Output Stream 1 Bit 5 Output Stream 2 Bit 6 Output Stream 3 Bit 7 Output Stream 4 Each bit can be reset by their respective stream reset.

20.6.16 CORBLBASE—Offset 40h

CORB Lower Base Address

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CORBLBASE: [AZLBAR] + 40h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

20.6.30 IC—Offset 60h

Immediate Command

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

IC: [AZLBAR] + 60h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	IMMEDIATE_COMMAND_WRITE: The command to be sent to the codec via the Immediate Command mechanism is written to this register. The command stored in this register is sent out over the link during the next available frame after a 1 is written to the ICB bit.

20.6.31 IR—Offset 64h

Immediate Response

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

IR: [AZLBAR] + 64h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RO	IMMEDIATE_RESPONSE_READ: This register contains the response received from a codec resulting from a command sent via the Immediate Command mechanism. If multiple codecs responded in the same frame there is no guarantee as to which response will be latched. Therefore broadcast type commands must not be issued via the Immediate Command mechanism.

20.6.32 ICS—Offset 68h

Immediate Command Status

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

ICS: [AZLBAR] + 68h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
RESERVED0				0
				IMMEDIATE_RESULT_VALID
				IMMEDIATE_COMMAND_BUSY

Bit Range	Default & Access	Description
15:2	0000h RO	RESERVED0: reserved
1	0h RW	IMMEDIATE_RESULT_VALID: This bit is set to a 1 by hardware when a new response is latched into the IRR register. This is a status flag indicating that software may read the response from the Immediate Response register. Software must clear this bit by writing a one to it before issuing a new command so that the software may determine when a new response has arrived.
0	0h RW	IMMEDIATE_COMMAND_BUSY: When this bit as read as a 0 it indicates that a new command may be issued using the Immediate Command mechanism. When this bit transitions from a 0 to a 1 via software writing a 1 the controller issues the command currently stored in the Immediate Command register to the codec over the link. When the corresponding response is latched into the Immediate Response register the controller hardware sets the IRV flag and clears the ICB bit back to 0. SW may write this bit to a 0 if the bit fails to return to 0 after a reasonable timeout period. Note that an Immediate Command must not be issued while the CORB RIRB mechanism is operating otherwise the responses conflict. This must be enforced by software.

20.6.33 DPLBASE—Offset 70h

DMA Position Lower Base Address

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

DPLBASE: [AZLBAR] + 70h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:7	0h RW	DMA_POSITION_LOWER_BASE_ADDRESS: Lower 32 bits of the DMA Position Buffer Base Address. This register field must not be written when any DMA engine is running or the DMA transfer may be corrupted. This same address is used by the Flush Control and must be programmed with a valid value before the FLCNRTL bit is set.
6:1	00h RO	DMA_POSITION_LOWER_BASE_UNIMPLEMENTED_BITS: Hardwired to 0 to force 128 byte buffer alignment for cache line write optimizations.
0	0h RW	DMA_POSITION_BUFFER_ENABLE: When this bit is set to a 1 the controller will write the DMA positions of each of the DMA engines to the buffer in main memory periodically typically once frame . Software can use this value to know what data in memory is valid data. The controller must guarantee that the values in the DMA Position Buffer that the software can read represent positions in the stream for which valid data exists in the Stream s DMA buffer. This has particular relevance in systems which support isochronous transfer the stream positions in the software visible memory buffer must represent stream data which has reached the Global Observation point.

20.6.34 DPUBASE—Offset 74h

DMA position Upper Base Address

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

DPUBASE: [AZLBAR] + 74h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
DMA_POSITION_UPPER_BASE_ADDRESS								

Bit Range	Default & Access	Description
31:0	0h RW	DMA_POSITION_UPPER_BASE_ADDRESS: Upper 32 bits of address of the DMA Position Buffer Base Address. This register field must not be written when the DMA engine is running or the DMA transfer may be corrupted.

20.6.35 ISD0CTL_STS—Offset 80h

Input Stream Descriptor 0 Control and status

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

ISD0CTL_STS: [AZLBAR] + 80h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00040000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RESERVED1	FIFO_READY	DESCRIPTOR_ERROR	FIFO_ERROR	RESERVED2	STREAM_NUMBER	BIDIRECTIONAL_DIRECTION_CONTROL	TRAFFIC_PRIORITY	STRIPE_CONTROL
						RESERVED0		
							DESCRIPTOR_ERROR_INTERRUPT_ENABLE	FIFO_ERROR_INTERRUPT_ENABLE
								INTERRUPT_ON_COMPLETION_ENABLE
								STREAM_RUN
								STREAM_RESET

Bit Range	Default & Access	Description
31:30	0h RO	RESERVED1: reserved
29	0h RO	FIFO_READY: For input streams the controller hardware will set this bit to 1 when a valid descriptor is loaded and the engine is ready for the RUN bit to be set.
28	0h RW	DESCRIPTOR_ERROR: Indicates that a serious error occurred during the fetch of a descriptor. This could be a result of a Master Abort a Parity or ECC error on the bus or any other error which renders the current Buffer Descriptor or Buffer Descriptor List useless. This error is treated as a fatal stream error as the stream cannot continue running. The RUN bit will be cleared and the stream will stop. Software may attempt to restart the stream engine after addressing the cause of the error and writing a 1 to this bit to clear it.
27	0h RW	FIFO_ERROR: Set when a FIFO error occurs. Bit is cleared by writing a 1 to this bit position. This bit is set even if an interrupt is not enabled. For an input stream this indicates a FIFO overrun occurring while the RUN bit is set. When this happens the FIFO pointers don't increment and the incoming data is not written into the FIFO thereby being lost.
26	0h RW	BUFFER_COMPLETION_INTERRUPT_STATUS: This bit is set to 1 by the hardware after the last sample of a buffer has been processed AND if the Interrupt on Completion IOC bit is set in the command byte of the buffer descriptor. It remains active until software clears it by writing a 1 to this bit position.
25:24	0h RO	RESERVED2: reserved

Bit Range	Default & Access	Description
23:20	0h RW	STREAM_NUMBER: This value reflects the Tag associated with the data being transferred on the link. When an input stream is detected on any of the SDIx signals that match this value the data samples are loaded into the FIFO associated with this descriptor. Note that while a single SDIx input may contain data from more than one stream number two different SDIx inputs may not be configured with the same stream number. 0000 Reserved Indicates Unused 0001 Stream 1 1110 Stream 14 1111 Stream 15
19	0h RO	BIDIRECTIONAL_DIRECTION_CONTROL: This bit is only meaningful for Bidirectional streams. Therefore this bit is hardwired to 0.
18	01h RO	TRAFFIC_PRIORITY: Hardwired to 1 indicating that all streams will use VC1 if it is enabled throughout the PCI Express registers.
17:16	0h RO	STRIPE_CONTROL: This field is meaningless for input streams.
15:5	000h RO	RESERVED0: reserved
4	0h RW	DESCRIPTOR_ERROR_INTERRUPT_ENABLE: Controls whether an interrupt is generated when the Descriptor Error Status DESE bit is set.
3	0h RW	FIFO_ERROR_INTERRUPT_ENABLE: This bit controls whether the occurrence of a FIFO error overrun for input will cause an interrupt or not. If this bit is not set bit 3 in the Status register will be set but the interrupt will not occur. Either way the samples will be dropped.
2	0h RW	INTERRUPT_ON_COMPLETION_ENABLE: This bit controls whether or not an interrupt occurs when a buffer completes with the IOC bit set in its descriptor. If this bit is not set bit 2 in the Status register will be set but the interrupt will not occur.
1	0h RW	STREAM_RUN: When set to 1 the DMA engine associated with this input stream will be enabled to transfer data in the FIFO to main memory. The SSYNC bit must also be cleared in order for the DMA engine to run. When cleared to 0 the DMA engine associated with this input stream will be disabled. Hardware will report a 0 in this bit when the DMA engine is actually stopped. Software must read a 0 from this bit before modifying related control registers or restarting the DMA engine.
0	0h RW	STREAM_RESET: Writing a 1 causes the corresponding stream to be reset. The Stream Descriptor registers except the SRST bit itself and FIFO s for the corresponding stream are reset. After the stream hardware has completed sequencing into the reset state it will report a 1 in this bit. Software must read a 1 from this bit to verify that the stream is in reset. Writing a 0 causes the corresponding stream to exit reset. When the stream hardware is ready to begin operation it will report a 0 in this bit. Software must read a 0 from this bit before accessing any of the stream registers. The RUN bit must be cleared before SRST is asserted.

20.6.36 ISDLPB—Offset 84h

Input Stream Descriptor 0 Link Position in Buffer

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

ISDLPB: [AZLBAR] + 84h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
15:0	00h RW	FIFO_SIZE: Indicates the maximum number of bytes that could be revicted by the controller at one time. This is the maximum number of bytes that may have been received from the link but not yet DMA d into memory and is also the maximum possible value that the PICB count will increase by at one time. The FIFO size is calculated based on factors including the stream format programmed in ISD0FMT register. As the default value is zero, SW must write to the respective ISD0FMT register to kick of the FIFO size calculation, and read back to find out the HW allocated FIFO size.

RESERVED0				DESCRIPTOR_ERROR_INTERRUPT_ENABLE				FIFO_ERROR_INTERRUPT_ENABLE				INTERRUPT_ON_COMPLETION_ENABLE				STREAM_RUN				STREAM_RESET																			

Bit Range	Default & Access	Description
31:30	0h RO	RESERVED1: reserved
29	0h RO	FIFO_READY: For input streams the controller hardware will set this bit to 1 when a valid descriptor is loaded and the engine is ready for the RUN bit to be set.
28	0h RW	DESCRIPTOR_ERROR: Indicates that a serious error occurred during the fetch of a descriptor. This could be a result of a Master Abort a Parity or ECC error on the bus or any other error which renders the current Buffer Descriptor or Buffer Descriptor List useless. This error is treated as a fatal stream error as the stream cannot continue running. The RUN bit will be cleared and the stream will stop. Software may attempt to restart the stream engine after addressing the cause of the error and writing a 1 to this bit to clear it.
27	0h RW	FIFO_ERROR: Set when a FIFO error occurs. Bit is cleared by writing a 1 to this bit position. This bit is set even if an interrupt is not enabled. For an input stream this indicates a FIFO overrun occurring while the RUN bit is set. When this happens the FIFO pointers don't increment and the incoming data is not written into the FIFO thereby being lost.
26	0h RW	BUFFER_COMPLETION_INTERRUPT_STATUS: This bit is set to 1 by the hardware after the last sample of a buffer has been processed AND if the Interrupt on Completion IOC bit is set in the command byte of the buffer descriptor. It remains active until software clears it by writing a 1 to this bit position.
25:24	0h RO	RESERVED2: reserved

Bit Range	Default & Access	Description
23:20	0h RW	STREAM_NUMBER: This value reflects the Tag associated with the data being transferred on the link. When an input stream is detected on any of the SDIx signals that match this value the data samples are loaded into the FIFO associated with this descriptor. Note that while a single SDIx input may contain data from more than one stream number two different SDIx inputs may not be configured with the same stream number. 0000 Reserved Indicates Unused 0001 Stream 1 1110 Stream 14 1111 Stream 15
19	0h RO	BIDIRECTIONAL_DIRECTION_CONTROL: This bit is only meaningful for Bidirectional streams. Therefore this bit is hardwired to 0.
18	01h RO	TRAFFIC_PRIORITY: Hardwired to 1 indicating that all streams will use VC1 if it is enabled throughout the PCI Express registers.
17:16	0h RO	STRIPE_CONTROL: This field is meaningless for input streams.
15:5	000h RO	RESERVED0: reserved
4	0h RW	DESCRIPTOR_ERROR_INTERRUPT_ENABLE: Controls whether an interrupt is generated when the Descriptor Error Status DESE bit is set.
3	0h RW	FIFO_ERROR_INTERRUPT_ENABLE: This bit controls whether the occurrence of a FIFO error overrun for input will cause an interrupt or not. If this bit is not set bit 3 in the Status register will be set but the interrupt will not occur. Either way the samples will be dropped.
2	0h RW	INTERRUPT_ON_COMPLETION_ENABLE: This bit controls whether or not an interrupt occurs when a buffer completes with the IOC bit set in its descriptor. If this bit is not set bit 2 in the Status register will be set but the interrupt will not occur.
1	0h RW	STREAM_RUN: When set to 1 the DMA engine associated with this input stream will be enabled to transfer data in the FIFO to main memory. The SSYNC bit must also be cleared in order for the DMA engine to run. When cleared to 0 the DMA engine associated with this input stream will be disabled. Hardware will report a 0 in this bit when the DMA engine is actually stopped. Software must read a 0 from this bit before modifying related control registers or restarting the DMA engine.
0	0h RW	STREAM_RESET: Writing a 1 causes the corresponding stream to be reset. The Stream Descriptor registers except the SRST bit itself and FIFO s for the corresponding stream are reset. After the stream hardware has completed sequencing into the reset state it will report a 1 in this bit. Software must read a 1 from this bit to verify that the stream is in reset. Writing a 0 causes the corresponding stream to exit reset. When the stream hardware is ready to begin operation it will report a 0 in this bit. Software must read a 0 from this bit before accessing any of the stream registers. The RUN bit must be cleared before SRST is asserted.

20.6.45 ISD1LPIB—Offset A4h

Input Stream Descriptor 1 Link Position in Buffer

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

ISD1LPIB: [AZLBAR] + A4h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00000000h

Input Stream Descriptor 1 Cyclic Buffer Length

Type: Memory Mapped I/O Register
(Size: 32 bits)

ISD1CBL: [AZLBAR] + A8h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CYCLIC_BUFFER_LENGTH								

Bit Range	Default & Access	Description
31:0	0h RW	CYCLIC_BUFFER_LENGTH: Indicates the number of bytes in the complete cyclic buffer. CBL must represent an integer number of samples. Link Position in Buffer LPIB will be reset when it reaches this value. Software may only write to this register after Global Reset Controller Reset or Stream Reset has occurred. This value should only be modified when the RUN bit is 0 . Once the RUN bit has been set to enable the engine software must not write to this register until after the next reset is asserted or transfers may be corrupted.

20.6.47 ISD1LVI—Offset ACh

Input Stream Descriptor 1 Last Valid Index

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

ISD1LVI: [AZLBAR] + ACh

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 0000h

15	12	8	4	0
0	0	0	0	0
RESERVED0				LAST_VALID_INDEX

Bit Range	Default & Access	Description
15:8	00h RO	RESERVED0: reserved
7:0	00h RW	LAST_VALID_INDEX: The value written to this register indicates the index for the last valid Buffer Descriptor in the BDL. After the controller has processed this descriptor it will wrap back to the first descriptor in the list and continue processing. LVI must be at least 1 i.e. there must be at least two valid entries in the buffer descriptor list before DMA operations can begin. This value should only be modified when the RUN bit is 0

20.6.48 ISD1FIFOW—Offset AEh

Input Stream Descriptor 1 FIFO Eviction Watermark

Access Method

Type: Memory Mapped I/O Register
(Size: 16 bits)

ISD1FIFOW: [AZLBAR] + AEh

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 0004h

20.6.51 ISD1BDLPLBA—Offset B8h

Access Method

ISD1BDLPLBA: [AZLBAR] + B8h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:7	0h RW	BUFFER_DESCRIPTOR_LIST_LOWER_BASE_ADDRESS: Lower address of the Buffer Descriptor List. This value should only be modified when the RUN bit is 0 or DMA transfers may be corrupted. Intel Reserved comment This field becomes WO and 0 s will be read when the Protect bit is set to 1.
6:1	00h RO	RESERVED0: reserved
0	0h RW	PROTECT: When this bit is set to 1 bits 31 7 0 of this register are WO and will return 0 s when read. When this bit is cleared to 0 bits 31 7 0 are RW. Note that this bit can only be changed when all four bytes of this register are written in a single write operation. If less than four bytes are written this bit retains its previous value. This bit is Intel Reserved.

20.6.52 ISD1BDLPUBA—Offset BCh

Input Stream Descriptor 1 Buffer Descriptor List Pointer Upper Base Address

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

ISD1BDLPUBA: [AZLBAR] + BCh

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	BUFFER_DESCRIPTOR_LIST_UPPER_BASE_ADDRESS: Upper 32 bit address of the Buffer Descriptor List. This value should only be modified when the RUN bit is 0 or the DMA transfer may be corrupted.

20.6.53 ISD2CTL_STS—Offset C0h

Input Stream Descriptor 2 Control and status

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

ISD2CTL_STS: [AZLBAR] + C0h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00040000h

[illegible]

Bit Range	Default & Access	Description
31:30	0h RO	RESERVED1: reserved
29	0h RO	FIFO_READY: For input streams the controller hardware will set this bit to 1 when a valid descriptor is loaded and the engine is ready for the RUN bit to be set.
28	0h RW	DESCRIPTOR_ERROR: Indicates that a serious error occurred during the fetch of a descriptor. This could be a result of a Master Abort a Parity or ECC error on the bus or any other error which renders the current Buffer Descriptor or Buffer Descriptor List useless. This error is treated as a fatal stream error as the stream cannot continue running. The RUN bit will be cleared and the stream will stop. Software may attempt to restart the stream engine after addressing the cause of the error and writing a 1 to this bit to clear it.
27	0h RW	FIFO_ERROR: Set when a FIFO error occurs. Bit is cleared by writing a 1 to this bit position. This bit is set even if an interrupt is not enabled. For an input stream this indicates a FIFO overrun occurring while the RUN bit is set. When this happens the FIFO pointers don't increment and the incoming data is not written into the FIFO thereby being lost.
26	0h RW	BUFFER_COMPLETION_INTERRUPT_STATUS: This bit is set to 1 by the hardware after the last sample of a buffer has been processed AND if the Interrupt on Completion IOC bit is set in the command byte of the buffer descriptor. Bit Range	Default & Access	Description
31:30	0h RO	RESERVED1: reserved
29	0h RO	FIFO_READY: For output streams the controller hardware will set this bit to a 1 while the output DMA FIFO contains enough data to maintain the stream on then link. This bit defaults to 0 on reset because the FIFO is cleared on a reset.
28	0h RW	DESCRIPTOR_ERROR: Indicates that a serious error occurred during the fetch of a descriptor. This could be a result of a Master Abort a Parity or ECC error on the bus or any other error which renders the current Buffer Descriptor or Buffer Descriptor List useless. This error is treated as a fatal stream error as the stream cannot continue running. The RUN bit will be cleared and the stream will stop. Software may attempt to restart the stream engine after addressing the cause of the error and writing a 1 to this bit to clear it.
27	0h RW	FIFO_ERROR: Set when a FIFO error occurs. Bit is cleared by writing a 1 to this bit position. This bit is set even if an interrupt is not enabled. For an output stream this indicates a FIFO under run when there are still buffers to send. The hardware should not transmit anything on the link for the associated stream if there is not valid data to send.
26	0h RW	BUFFER_COMPLETION_INTERRUPT_STATUS: This bit is set to 1 by the hardware after the last sample of a buffer has been processed AND if the Interrupt on Completion IOC bit is set in the command byte of the buffer descriptor. It remains active until software clears it by writing a 1 to this bit position.
25:24	0h RO	RESERVED2: reserved
23:20	0h RW	STREAM_NUMBER: This value reflects the Tag associated with the data being transferred on the link. When data controlled by this descriptor is sent out over the link it will have this stream number encoded on the SYNC signal. 0000 Reserved Indicates Unused 0001 Stream 1 1110 Stream 14 1111 Stream 15
19	0h RO	BIDIRECTIONAL_DIRECTION_CONTROL: This bit is only meaningful for Bidirectional streams. Therefore this bit is hardwired to 0.
18	01h RO	TRAFFIC_PRIORITY: Hardwired to 1 indicating that all streams will use VC1 if it is enabled throughout the PCI Express registers.
17:16	0h RO	STRIPE_CONTROL: For output streams it controls the number of SDO signals to stripe data across. Only one SDO is supported in the HD Audio controller. Therefore it is hardwired to 0 s.
15:5	000h RO	RESERVED0: reserved

Output Stream Descriptor 0 Link Position in Buffer

Type: Memory Mapped I/O Register
(Size: 32 bits)

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RO	LINK_POSITION_IN_BUFFER: Indicates the number of bytes that have been received off the link. This register will count from 0 to the value in the Cyclic Buffer Length register and then wrap to 0.

20.6.80 OSD1CTL_STS—Offset 120h

Output Stream Descriptor 1 Control and status

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

OSD1CTL_STS: [AZLBAR] + 120h

AZLBAR Type: PCI Configuration Register (Size: 32 bits)

AZLBAR Reference: [B:0, D:27, F:0] + 10h

Default: 00040000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0

						RESERVED0		
							DESCRIPTOR_ERROR_INTERRUPT_ENABLE	FIFO_ERROR_INTERRUPT_ENABLE
								INTERRUPT_ON_COMPLETION_ENABLE
								STREAM_RUN
								STREAM_RESET

Bit Range	Default & Access	Description
31:30	0h RO	RESERVED1: reserved
29	0h RO	FIFO_READY: For output streams the controller hardware will set this bit to a 1 while the output DMA FIFO contains enough data to maintain the stream on then link. This bit defaults to 0 on reset because the FIFO is cleared on a reset.
28	0h RW	DESCRIPTOR_ERROR: Indicates that a serious error occurred during the fetch of a descriptor. This could be a result of a Master Abort a Parity or ECC error on the bus or any other error which renders the current Buffer Descriptor or Buffer Descriptor List useless. This error is treated as a fatal stream error as the stream cannot continue running. The RUN bit will be cleared and the stream will stop. Software may attempt to restart the stream engine after addressing the cause of the error and writing a 1 to this bit to clear it.
27	0h RW	FIFO_ERROR: Set when a FIFO error occurs. Bit is cleared by writing a 1 to this bit position. This bit is set even if an interrupt is not enabled. For an output stream this indicates a FIFO under run when there are still buffers to send. The hardware should not transmit anything on the link for the associated stream if there is not valid data to send.
26	0h RW	BUFFER_COMPLETION_INTERRUPT_STATUS: This bit is set to 1 by the hardware after the last sample of a buffer has been processed AND if the Interrupt on Completion IOC bit is set in the command byte of the buffer descriptor. It remains active until software clears it by writing a 1 to this bit position.
25:24	0h RO	RESERVED2: reserved

Bit Range	Default & Access	Description
23:20	0h RW	STREAM_NUMBER: This value reflects the Tag associated with the data being transferred on the link. When data controlled by this descriptor is sent out over the link it will have this stream number encoded on the SYNC signal. 0000 Reserved Indicates Unused 0001 Stream 1 1110 Stream 14 1111 Stream 15
19	0h RO	BIDIRECTIONAL_DIRECTION_CONTROL: This bit is only meaningful for Bidirectional streams. Therefore this bit is hardwired to 0.
18	01h RO	TRAFFIC_PRIORITY: Hardwired to 1 indicating that all streams will use VC1 if it is enabled throughout the PCI Express registers.
17:16	0h RO	STRIPE_CONTROL: For output streams it controls the number of SDO signals to stripe data across. Only one SDO is supported in the HD Audio controller. Therefore it is hardwired to 0 s.
15:5	000h RO	RESERVED0: reserved
4	0h RW	DESCRIPTOR_ERROR_INTERRUPT_ENABLE: Controls whether an interrupt is generated when the Descriptor Error Status DESE bit is set.
3	0h RW	FIFO_ERROR_INTERRUPT_ENABLE: This bit controls whether the occurrence of a FIFO error under run for output will cause an interrupt or not. If this bit is not set bit 3 in the Status register will be set but the interrupt will not occur. Either way the samples will be dropped.
2	0h RW	INTERRUPT_ON_COMPLETION_ENABLE: This bit controls whether or not an interrupt occurs when a buffer completes with the IOC bit set in its descriptor. If this bit is not set bit 2 in the Status register will be set but the interrupt will not occur.
1	0h RW	STREAM_RUN: When set to 1 the DMA engine associated with this output stream will be enabled to transfer data in the main memory to FIFO. The SSYNC bit must also be cleared in order for the DMA engine to run. For output streams the cadence generator is reset whenever the RUN bit is set. When cleared to 0 the DMA engine associated with this output stream will be disabled. Hardware will report a 0 in this bit when the DMA engine is actually stopped. Software must read a 0 from this bit before modifying related control registers or restarting the DMA engine.
0	0h RW	STREAM_RESET: Writing a 1 causes the corresponding stream to be reset. The Stream Descriptor registers except the SRST bit itself and FIFO s for the corresponding stream are reset. After the stream hardware has completed sequencing into the reset state it will report a 1 in this bit. Software must read a 1 from this bit to verify that the stream is in reset. Writing a 0 causes the corresponding stream to exit reset. When the stream hardware is ready to begin operation it will report a 0 in this bit. Software must read a 0 from this bit before accessing any of the stream registers. The RUN bit must be cleared before SRST is asserted.

21 Low Power Engine (LPE) for Audio (I²S)

The Low Power Engine for Audio provides acceleration for common audio and voice functions. The voice and audio engine provides a mechanism for rendering audio and voice streams and tones from the operating system, applications to an audio or voice codec, and ultimately to the speaker, headphones, or Bluetooth headsets.

Audio streams in the SoC can be encoded and decoded by the Low Power Engine (LPE) in the Audio subsystem.

LPE Audio provides three external I²S audio interfaces.

Note: LPE_I2S[1:0] are multiplexed on the same balls as High Definition Audio.

Note: When LPE is active, the High Definition Audio functionality is disabled.

21.1 Signal Descriptions

See [Chapter 2, “Physical Interfaces”](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal’s function

**Table 226. LPE Signals**

Signal Name	Direction Plat. Power	Description
LPE_I2S2[0:2]_CLK	I/O V1P8S	Clock signal for I ² S
LPE_I2S2[0:2]_FRM	I/O V1P8S	Frame select signal for I ² S
LPE_I2S2[0:2]_DATAIN	I V1P8S	RX data for I ² S
LPE_I2S2[0:2]_DATAOUT	O V1P8S	TX data for I ² S

† All LPE signals are muxed and may be used by other functions.

21.2 Features

The LPE Audio Subsystem consists of the following:

- Integrated, power-efficient 32-bit architecture core with 24-bit audio processing instructions
- Core processing speeds up to 343 MHz
- Closely Coupled Memories (CCMs)
 - 80KB Instruction RAM
 - 160KB Data RAM
 - 48KB Instruction Cache
 - 96KB Data Cache
- Very low-power consumption coupled with high-fidelity 24-bit audio
- Dual-issue, static, super-scalar VLIW processing engine
- Mode-less switching between 16-, 24-, and 64-bit dual-issue instructions
- Dual MACs which can operate with 32 x 16-bit and/or 24 x 24-bit operands
- Inter-Process Communication (IPC) mechanism to communicate with the SoC Processor Core including 4KB mailbox memory
- Flexible audio interfaces include three SSPs with I²S port functionality for I-directional audio transfers
 - I²S mode supports PCM payloads
 - Frame counters for all I²S ports
- High Performance DMA
 - DMA IP to support multiple outstanding transactions
 - Interleaved scatter-gather support for Audio DMA transfers
- Clock switching logic including new frequency increments

- External timer function with an always running clock.

The LPE core runs at a peak clock frequency of 343 MHz and has dedicated on-chip program and data memories and caches. The LPE core can access shared SRAM blocks, and external DRAM through OCP fabric. It communicates with audio peripherals using the audio sub-fabric, and employs Inter-Processor Communication (IPC) mechanism to communicate with the SoC Processor Core.

The Audio subsystem includes two OCP-based DMA engines. These DMA engines support single and multi-block transfers. They can be configured to transfer data between DRAM and audio CCMs or transfer data between CCMs and the audio peripheral interfaces

All these interfaces are peripherals in the Audio subsystem. LPE, LPE DMA, or the SoC processor core may access the peripherals during normal operation. The PMC may access all peripherals during specific tasks such as at boot time or during power state changes. A complete audio solution based on an internal audio processing engine which includes several I²S-based output ports.

The audio core used is a dedicated audio DSP core designed specifically for audio processing (decoding, post-processing, mixing, etc.)

Note: LPE requires systems with more than 512MB memory. This is required since the LPE firmware must reside at a stolen memory location on 512MB boundaries below 3 GiB. The LPE firmware itself is ~1MB, and is reserved by BIOS for LPE use.

21.3 Detailed Block Level Description

21.3.1 LPE Core

The LPE core in the SoC runs at maximum frequency of 343 MHz and interfaces with the rest of the SoC system through the OCP bus. It is one of the masters on the Audio Sub-Fabric. The SoC Processor Core and LPE DMA engines are the other masters on the fabric. The following figure shows the LPE core and its interfaces.

Figure 106. Audio Cluster Block Diagram

The main DSP hardware is a two-multiplier, multiply/accumulate unit, a register file LPE_PR to hold pairs of 24-bit data items, a register file LPE_OR to hold 56-bit accumulator values, an arithmetic/logic unit to operate on the LPE_PR and LPE_OR values, and a shift unit to operate on the LPE_PR and LPE_OR values. The multiply/accumulate unit also supports multiplication of 32-bit values from LPE_OR registers by 16-bit values from LPE_PR registers, with the 48-bit result written or accumulated in the LPE_OR register. The instructions for the DSP subsystems are built from operations that are divided into two sets: the slot 0 set and the slot 1 set. In each execution cycle, zero or one operations from each set can be executed independently according to the static bundling expressed in the machine code.

21.3.2 Memory Architecture

The LPE core is configured to use local memory and local caches. It has 80KB of Instruction Closely Coupled Memory (CCM), 160KB of Data CCM, 48KB of Instruction Cache and 96KB of Data Cache. The LPE core also has access to 4KB of mailbox memory and external DRAM.

Figure 107. Memory Connections for LPE

21.3.3 Instruction Closely Coupled Memory (CCM)

Instruction CCM for the core is used for loading commonly used routines as well as time-critical processing. Examples of time critical processing are acoustic echo cancellation and noise cancellation during voice calls.

Instruction CCM is initialized after reset by an external DMA controller. Runtime update of instruction CCM can be done either using explicit instructions or using an external DMA controller with inbound access.

21.3.4 Data Closely Coupled Memory (CCM)

Data CCM can be initialized after reset by an external DMA controller using inbound access. Runtime update of data CCM can be done either using stores to Data CCM or using an external DMA controller with inbound access.

21.3.5 Mailbox Memory and Data Exchange

The mailbox memory is a shared memory region in LPE address space that is accessible by the SoC Processor Core, PMC, and LPE. It is used when Doorbell registers cannot hold all the information that one processor wishes to communicate to the other. A typical example of such data blocks are audio stream related parameters when starting a new stream. The structures of data communicated through the mailbox are not defined in hardware so that software may partition the mailbox memory in any desired way and create any meaningful structures required.

21.4 Software Implementation Considerations

21.4.1 SoC Processor Core Cache Coherence

Traffic generated by the LPE core is considered non-cacheable and non-coherent with respect to the SoC Processor Core cache. DMA traffic is considered cacheable and checked for coherency with the SoC Processor Core cache.

Implications of this implementation are as follows:

- All code and tables for the LPE core need to be explicitly flushed from the SoC Processor Core cache if they are ever accessed.
- If the LPE core directly accesses data buffers in system DDR, the driver must explicitly flush the buffer from the SoC Processor Core cache
- If DMA accesses data buffers from system DRAM, the driver need not flush the data buffer from the SoC Processor Core cache.

21.4.2 Interrupts

21.4.2.1 LPE Peripheral Interrupts

Each of the LPE peripherals generates its own interrupts. SSP0, SSP1, and SSP2 have one interrupt each. Each of the DMA channels have individual interrupt lines. These interrupts are connected to the LPE core through the PISR register. The same interrupts are routed to IOAPIC through the ISRX register. The LPE core and SoC Processor Core have individual masks to enable these interrupts.

21.4.2.2 Interrupts Between SoC Processor Core and the LPE

The interrupts between the SoC Processor Core and the LPE are handled through the inter-processor communication registers. Whenever the SoC Processor Core writes to the IPCX communication register an interrupt is generated to the LPE. The LPE firmware sees there is a message waiting from the SoC Processor Core, and reads the IPCX register for the data. This data is a pre-configured message, where the message structure has been decided beforehand between the SoC Processor Core and the LPE. Similarly we have the IPCD register for the communication between the LPE and SoC Processor Core. Once the LPE writes to the IPCD register, an interrupt should be generated for the SoC Processor Core and the SoC Processor Core should read the message from the IPCD register and act accordingly. From a software viewpoint, the mechanism remains the same as before. From a hardware view point, the interrupt to IA-32 gets routed by means of the IOAPIC block. The IPC from Audio to SoC Processor Core gets a dedicated interrupt line to the IOAPIC.

21.4.2.3 Interrupts between PMC and LPE

The interrupts between PMC and LPE are also handled using Inter Process Communication registers.

21.4.3 Power Management Options for the LPE Core

- WAITI
 - Allows the LPE core to suspend operation until an interrupt occurs by executing the optional WAITI instruction.
- External Run/Stall Control Signal
 - This processor input allows external logic to stall large portions of the LPE pipeline by shutting off the clock to much of the processor's logic to reduce operating power when the LPE computational capabilities are not immediately needed by the system.

Note: Using the WAITI instruction to power down the processor will save more power than use of the external run/stall signal because the WAITI instruction disables more of the LPE's internal clocks.

21.4.4 External Timer

This timer always runs from SSP clock (before M/N divider) at 19.2/25MHz. The timer starts running once the run bit (refer to the External timer register definition for details) is set and the clear bit is cleared.

The timer generates an Interrupt pulse when the counter value matches the “match” value. The interrupt does not get generated if the match value is set to “0”. The timer runs in free running mode and rolls over after all 32 bits have become all 1’s.

The timer continues to run as long as the run bit is set. Once the run bit is cleared the timer holds the current value. The clear bit needs to be set to restart the timer from “0”.

21.5 Clocks

21.5.1 Clock Frequencies

Table 227 shows the clock frequency options for the Audio functional blocks.

Table 227. Clock Frequencies

Clock	Frequency	Notes
Audio core	25/50/100/200/267/343 MHz	Audio input clock trunk. CCU drives one of several frequencies as noted.
DMA 0	25/50 MHz	DMA clock
DMA1	25/50 MHz	DMA clock
Audio fabric clock	25/50 MHz	Fabric clock derived from audio core clock
SSP0 Clock	Fabric side: 25/50 MHz Link side: Up to 19.2/25 MHz	SSP0 clock domains
SSP1 Clock	Fabric side: 25/50 MHz Link side: Up to 19.2/25 MHz	SSP1 clock domains
SSP2 Clock	Fabric side: 25/50 MHz Link side: Up to 19.2/25 MHz	SSP2 clock domains

21.5.2 50 MHz Clock for LPE

50 MHz, the 2X OSC clock, is added to increase MIPS for low power MP3 mode. This frequency will be supplied by the clock doubler internal to the SoC’s Clock Control Unit.

21.5.3 Cache and CCM Clocking

Data CCM, Data cache, Instruction CCM, and Instruction Cache run off of the LPE clock. These memories are in a single clock domain.

Note: All Data CCM and Instruction CCM run in the same clock domain.

21.5.4 SSP Clocking

SSP could be used as either clock masters or clock slaves. Consequently, these IP have dual clock domains.

The first clock domain is clocked from an internal clock (e.g., fabric clock) and is used for generic logic like interrupt generation and register access.

The second clock domain drives the serial shift register (either driven internally or externally). When driven internally, this clock can be sourced from XTAL clock 25 MHz or PLL 19.2 MHz. These clocks are then divided down within the serial interface IP to generate the final bit clock for the interface.

After power on, if the SSP input IO clock is in high state, first transition of the clock from high to low may be missing due to the Soc clock gating logic.

Note: “Frame Master” mode cannot be used when operating as clock slave and “Frame Slave” mode cannot be used when operating as clock master.

21.5.5 M/N Divider

LPE SSP in master mode uses the SSP CCLK to drive the serial clock. It has very limited option to divide CCLK. An M/N divider is added between the 19.2/25 MHz clock (XOSC) from CCU to each SSP CCLK input as shown in following diagram:

Figure 108.SSP CCLK Structure

Note: The maximum SSP CCLK frequency is listed in Table 132.

The LPE M/N divider is designed to produce a clock signal for the SSP block used in master mode. The divider is based on a generic NOM/DENOM divider. The supplied Master clock is 25 MHz (XTAL) or 19.2 MHz (LPPLL), but usually be used by the 25 MHz clock.

This mechanism is good for a wide spectrum of generated clocks. Two registers must be configured to get the target SSP clock. The values for the Nominator and Denominator registers are the smallest divider of:

$$\frac{\text{Nominator}}{\text{Denominator}} = \frac{\text{Source_clock}}{\text{Target_clock}}$$

21.5.5.1 Example

If we want to generate 17.64 MHz (=400x44.1 KHz) output clock out of 25 MHz clock, we need to program "NOM = 441" and "DENOM = 625":

$$17.64 \text{ MHz} = (441/625) \times 25 \text{ MHz}$$

In general the M over N can generate fractional divisor that could be used for generating the required clocks for Audio codec. [Table 228](#) describes some configuration options of this generic divider:

Table 228. M/N Values, Examples

Source Clock Frequency	Requested Clock	M/N Value
25 MHz	48 KHz	6/3125
	48K x 24 = 1.152 MHz	1152/25000
	48K x 32 = 1.536 MHz	1536/25000
	48K x 64 = 3.072 MHz	3072/25000
	44.1 KHz	441/250000
	48K x 400 = 19.2 MHz	96/125
	44.1K x 400 = 17.64 MHz	441/625

21.5.5.2 Accuracy and Jitter

The output of the M/N is equal to the desired clock in average with Jitter of 20nTXE for 25 MHz input clock.

21.5.5.3 Configuration

Following configurable fields per M/N divider/SSP are in LPE shim registers:

**Table 229. M/N Configurable Fields**

Field	Width	Description
Bypass	1 bit	When set M/N divider is bypass. Clock from CCU is connected directly to SSP CCLK
EN	1 bit	Enable the divider
Update	1 bit	Update divider parameters
M Value	20 bits	Nominator value
N Value	20 bits	Denominator value

21.6 SSP (I²S)

The SoC audio subsystem consists of the LPE Audio Engine and three Synchronous Serial Protocol (SSP) ports. These ports are used in PCM mode and enable simultaneous support of voice and audio streams over I²S. The SoC audio subsystem also includes two DMA controllers dedicated to the LPE. The LPE DMA controllers are used for transferring data between external memory and CCMs, between CCMs and the SSP ports, and between CCMs. All peripheral ports can operate simultaneously.

21.6.1 Introduction

The Enhanced SSP Serial Ports are full-duplex synchronous serial interfaces. They can connect to a variety of external analog-to-digital (A/D) converters, audio, and telecommunication codecs, and many other devices which use serial protocols for transferring data. Formats supported include National* Microwire, Texas Instruments* Synchronous Serial Protocol (SSP), Motorola* Serial Peripheral Interface (SPI) protocol and a flexible Programmable Serial Port protocol (PSP).

The Enhanced SSPs operate in master mode (the attached peripheral functions as a slave) or slave mode (the attached peripheral functions as a master), and support serial bit rates from 0 to 25 Mbps, dependent on the input clock. Serial data formats range from 4 to 32-bits in length. Two on-chip register blocks function as independent FIFOs for transmit and receive data.

FIFOs may be loaded or emptied by the system processor using single transfers or DMA burst transfers of up to the FIFO depth. Each 32-bit word from the bus fills one entry in a FIFO using the lower significant bits of a 32-bit word.

21.6.2 SSP Features

The SSP port features are:

- Inter-IC Sound (I²S) protocols, are supported by programming the Programmable Serial Protocol (PSP).
- One FIFO for transmit data (TXFIFO) and a second, independent, FIFO for receive data (RXFIFO), where each FIFO is 16 samples deep x 32 bits wide
- Data sample sizes from 8, 16, 18 and 24bits

- 12.5 Mbps maximum serial bit-rate in both modes: master and slave.
- Clock master or slave mode operations
- Receive-without-transmit operation
- Network mode with up to eight time slots for PSP formats, and independent transmit/receive in any/all/none of the time slots.
- After updating SSP configuration, for example active slot count, the SSP will need to be disabled and enabled again. In other words, a SSP will not function correctly if a user changes the configuration setting on the fly.

21.6.3 Operation

Serial data is transferred between the LPE core or the SoC Processor Core and an external peripheral through FIFOs in one of the SSP ports. Data transfers between an SSP port and memory are initiated by either the LPE core or the SoC Processor Core using programmed I/O, or by DMA bursts. Although it is possible to initiate transfers directly from the SoC Processor Core, current driver design uses LPE for all PCM operations. Separate transmit and receive FIFOs and serial data paths permit simultaneous transfers in both directions to and from the external peripheral, depending on the protocols chosen.

Programmed I/O can transfer data between:

- The LPE core and the FIFO Data register for the TXFIFO
- The SoC Processor Core and the FIFO Data register for the TXFIFO
- The LPE core and the FIFO Data register for the RXFIFO
- The SoC Processor Core and the FIFO Data register for the RXFIFO
- The SoC Processor Core and the control or status registers
- The LPE core and the control or status registers

DMA bursts can transfer data between:

- Universal memory and the FIFO Data register for the TXFIFO
- Universal memory and the FIFO Data register for the RXFIFO
- Universal memory and the sequentially addressed control or status registers

21.6.4 LPE and DMA FIFO Access

The LPE or DMA access data through the Enhanced SSP Port's Transmit and Receive FIFOs. An LPE access takes the form of programmed I/O, transferring one FIFO entry per access. LPE accesses would normally be triggered off of an SSSR Interrupt and must always be 32 bits wide. LPE Writes to the FIFOs are 32 bits wide, but the serializing logic will ignore all bits beyond the programmed FIFO data size (EDSS/DSS value). LPE Reads to the FIFOs are also 32 bits wide, but the Receive data written into the RX FIFO (from the RXD line) is stored with zeroes in the MSBs down to the programmed data size. The FIFOs can also be accessed by DMA bursts, which must be

in multiples of 1, 2 or 4 bytes, depending upon the EDSS value, and must also transfer one FIFO entry per access. When the SSCR0.EDSS bit is set, DMA bursts must be in multiples of 4 bytes (the DMA must have the Enhanced SSP configured as a 32-bit peripheral). The DMA's width register must be at least the SSP data size programmed into the SSP control registers EDSS and DSS. The FIFO is seen as one 32-bit location by the processor. For Writes, the Enhanced SSP port takes the data from the Transmit FIFO, serializes it, and sends it over the serial wire (I2S[2:0]_DATAOUT) to the external peripheral. Receive data from the external peripheral (on I2S[2:0]_DATAIN) is converted to parallel words and stored in the Receive FIFO.

A programmable FIFO trigger threshold, when exceeded, generates an Interrupt or DMA service request that, if enabled, signals the CPU or DMA respectively to empty the Receive FIFO or to refill the Transmit FIFO.

The Transmit and Receive FIFOs are differentiated by whether the access is a Read or a Write transfer. Reads automatically target the Receive FIFO, while Writes will write data to the Transmit FIFO. From a memory-map perspective, they are at the same address. FIFOs are 16 samples deep by 32 bits wide. Each read or write is to 1 SSP sample.

21.6.5 Supported Formats

The SSP consists of four pins that are used to transfer data between the SoC and external Audio codecs, modems, or other peripherals. Although four serial-data formats exist, each has the same basic structure, and in all cases the following pins are used in the following manner:

- I2Sx_CLK—Defines the bit rate at which serial data is driven onto and sampled from the port
- I2Sx_FRM—Defines the boundaries of a basic data "unit," comprised of multiple serial bits
- I2Sx_DATAIN—The serial data path for transmitted data, from system to peripheral
- I2Sx_DATAOUT—The serial data path for received data, from peripheral to system

A data frame can contain from 4 to 32 bits, depending on the selected format. Serial data is transmitted most significant bit first. The Programmable Serial Protocol (PSP) format is used to implement I²S.

Master and Slave modes are supported. When driven by the Enhanced SSP, the I2Sx_CLK only toggles during active transfers (not continuously) unless ECRA/ECRB functions are used. When the I2Sx_CLK is driven by another device, it is allowed to be either continuous or only driven during transfers, but certain restrictions on PSP parameters apply.

Normally, the serial clock (I2Sx_CLK), if driven by the Enhanced SSP Port, only toggles while an active data transfer is underway. There are several conditions, however, that may cause the clock to run continuously. If the Receive With Out Transmit mode is enabled by setting the SSCR1.RWOT bit to 1, the I2Sx_CLK will toggle regardless of whether Transmit data exists within the Transmit FIFO. The I2Sx_CLK will also toggle continuously if the Enhanced SSP is in Network mode, or if ECRA, or ECRB is enabled. At other times, I2Sx_CLK will be held in an inactive I2Sx_FRM or idle state, as defined by the specified protocol under which it operates.

21.6.5.1 Programmable Serial Protocol (PSP)

There are many variations of the frame behavior for different codecs and protocol formats. To allow flexibility the PSP format allows I2Sx_FRM to be programmable in direction, delay, polarity, and width. Master and Slave modes are supported. PSP can be programmed to be either full or half duplex.

The I2Sx_CLK function behavior varies between each format. PSP lets programmers choose which edge of I2Sx_CLK to use for switching Transmit data, and for sampling Receive data. In addition, programmers can control the idle state for I2Sx_CLK and the number of active clocks that precede and follow the data transmission.

The PSP format provides programmability for several parameters that determine the transfer timings between data samples. There are four possible serial clock sub-modes, depending on the I2Sx_CLK edges selected for driving data and sampling received data, and the selection of idle state of the clock.

For the PSP format, the Idle and Disable modes of the I2Sx_DATAOUT, I2Sx_CLK, and I2Sx_FRM are programmable by means of the SSPSP.ETDS, SSPSP.SCMODE and SSPSP.SFRMP bits. When Transmit data is ready, the I2Sx_CLK will remain in its Idle state for the number of serial clock (I2Sx_CLK) clock periods programmed within the Start Delay (SSPSP.STRTDLY) field. I2Sx_CLK will then start toggling, I2Sx_DATAOUT will remain in the idle state for the number of cycles programmed within the Dummy Start (SSPSP.DMYSTRT) field. The I2Sx_FRM signal will be asserted after the number of half-clocks programmed in the SSPSP.SFRDLY field. The I2Sx_FRM signal will remain asserted for the number of clocks programmed within the SSPSP.SFRMWDTH then de-assert. Four to 32 bits can be transferred per frame. Once the last bit (LSB) is transferred, the I2Sx_CLK will continue toggling based off the Dummy Stop (SSPSP.DMYSTOP) field. I2Sx_DATAOUT either retains the last value transmitted or is forced to zero, depending on the value programmed within the End of Transfer Data State (SSPSP.ETDS) field, when the controller goes into Idle mode, unless the Enhanced SSP port is disabled or reset (which forces I2Sx_DATAOUT to zero).

With the assertion of I2Sx_FRM, Receive data is simultaneously driven from the peripheral on I2Sx_DATAIN, most significant bit first. Data transitions on I2Sx_CLK based on the Serial Clock Mode selected and is sampled by the controller on the opposite edge. When the Enhanced SSP is a master to the frame synch (I2Sx_FRM) and a slave to the clock (I2Sx_CLK), then at least three extra clocks (I2Sx_CLKs) will be needed at the beginning and end of each block of transfers to synchronize control signals from the APB clock domain into the SSP clock domain (a block of transfers is a group of back-to-back continuous transfers).

Figure 109. Programmable Serial Protocol Format

Figure 110. Programmable Serial Protocol Format (Consecutive Transfers)

**Table 230. Programmable Protocol Parameters**

Symbol	Definition (Register.Bit Field)	Range	Units
	Serial Clock Mode (SSPSP.SCMODE)	(Drive, Sample, I2Sx_CLK Idle) 0 = Fall, Rise, Low 1 = Rise, Fall, Low 2 = Rise, Fall, High 3 = Fall, Rise, High	
	Serial Frame Polarity (SSPSP.SFRMP)	High or Low	
T1	Start Delay (SSPSP.STRTDLY)	0–7	Clock Period
T2	Dummy Start (SSPSP.DMYSTRT)	0–3	Clock Period
T3	Data Size (SSCRO.EDSS AND SSCRO.DSS)	4–32	Clock Period
T4	Dummy Stop (SSPSP.DMYSTOP)	0–3	Clock Period
T5	I2Sx_FRM Delay (SPSP.SFRMDLY)	0–88	Half Clock Period
T6	I2Sx_FRM Width (SSPSP.SFRMWDTH)	1–44	Clock Period
	End of Transfer Data State (SSPSP.ETDS)	Low or [bit 0]	

Note: The I2Sx_FRM Delay must not extend beyond the end of T4. I2Sx_FRM Width must be asserted for at least 1 I2Sx_CLK, and should be de-asserted before the end of the T4 cycle (for example, in terms of time, not bit values, $(T5 + T6) \leq (T1 + T2 + T3 + T4)$, $1 \leq T6 < (T2 + T3 + T4)$, and $(T5 + T6) \geq (T1 + 1)$ to ensure that I2Sx_FRM is asserted for at least 2 edges of the I2Sx_CLK). The T1 Start Delay value should be programmed to 0 when the I2Sx_CLK is enabled by either of the SSCR1.ECRA or SSCR1.ECRB bits. While the PSP can be programmed to generate the assertion of I2Sx_FRM during the middle of the data transfer (after the MSB was sent), the Enhanced SSP will not be able to receive data in Frame slave mode (SSCR1SFRMDIR = 1) if the assertion of Frame is not before the MSB is sent (i.e. $T5 \leq T2$ if SSCR1.SFRMDIR = 1). Transmit Data will transition from the “End of Transfer Data State” to the next MSB value upon the assertion of Frame. The Start Delay field should be programmed to 0 whenever I2Sx_CLK or I2Sx_FRM is configured as an input. Clock state is not defined between two active frame periods. Clock can be active or inactive between two active frame periods.

21.7 Programming Model

The CPU or DMA access data through the Enhanced SSP Port’s Transmit and Receive FIFOs. A CPU access takes the form of programmed I/O, transferring one FIFO entry per access. CPU accesses would normally be triggered off of an SSSR Interrupt and

must always be 32 bits wide. The CPU Writes to the FIFOs are 32 bits wide, but the serializing logic will ignore all bits beyond the programmed FIFO data size (EDSS/DSS value). CPU Reads to the FIFOs are also 32 bits wide, but the Receive data written into the RX FIFO (from the RXD line) is stored with zeroes in the MSBs down to the programmed data size. The FIFOs can also be accessed by DMA bursts, which must be in multiples of 1, 2, or 4 bytes, depending upon the EDSS value, and must also transfer one FIFO entry per access. When the SSCR0.EDSS bit is set, DMA bursts must be in multiples of 4 bytes (the DMA must have the Enhanced SSP configured as a 32-bit peripheral). The DMA DCMD.width register must be at least the SSP data size programmed into the SSP control registers EDSS and DSS. The FIFO is seen as one 32-bit location by the processor. For Writes, the Enhanced SSP port takes the data from the Transmit FIFO, serializes it, and sends it over the serial wire (I2Sx_DATAOUT) to the external peripheral. Receive data from the external peripheral (on I2Sx_DATAIN) is converted to parallel words and stored in the Receive FIFO.

A programmable FIFO trigger threshold, when exceeded, generates an Interrupt or DMA service request that, if enabled, signals the IA-32 CPU or DMA respectively to empty the Receive FIFO or to refill the Transmit FIFO. The Transmit and Receive FIFOs are differentiated by whether the access is a Read or a Write transfer. Reads automatically target the Receive FIFO, while Writes will write data to the Transmit FIFO. From a memory-map perspective, they are at the same address. Each read or write is 1 SSP sample.

21.7.1 PIO and DMA Programming Considerations

All CPU and DMA accesses transfer one FIFO entry per access. Data in the FIFOs is always stored with one 32-bit value per data sample, regardless of the format data word length. Within each 32-bit field, the stored data sample is right-justified, with the least significant bit of the word in bit 0. In the Receive FIFO, unused bits are packed as zeroes above the most significant bit. In the Transmit FIFO, unused don't-care bits are above the most significant bit (i.e., DMA and CPU access do not have to write to the unused bit locations). Logic in the Enhanced SSP automatically formats data in the Transmit FIFO so that the sample is properly transmitted on I2Sx_DATAOUT in the selected frame format.

Two separate and independent FIFOs are present for Transmit (to peripheral) and Receive (from peripheral) serial data. FIFOs are filled or emptied by programmed I/O or DMA bursts.

21.7.1.1 Programmed IO Considerations

FIFO filling and emptying can be performed by the processor in response to an Interrupt from the FIFO logic. Each FIFO has a programmable FIFO trigger threshold at which an Interrupt is triggered. When the number of entries in the Receive FIFO exceeds the SSCR1.RFT value, an interrupt is generated (if enabled), which signals the CPU to empty the Receive FIFO. When the number of entries in the Transmit FIFO is less than or equal to the SSCR1.TFT value plus 1, an Interrupt is generated (if enabled), which signals the CPU to refill the Transmit FIFO.

Users can also poll the Enhanced SSP Status register to determine how many samples are in a FIFO, and whether the FIFO is full or empty. Software is responsible for ensuring that the proper RFT and TFT values are chosen to prevent ROR and TUR error conditions.

Note: If the software attempts to read from an empty Receive FIFO, it will receive a duplicate of the previously read value.

21.7.1.2 DMA Considerations

The DMA controller can also be programmed to transfer data to and from the Enhanced SSP FIFOs. To prevent over-runs of the Transmit FIFO or under-runs of the Receive FIFO when using the DMA, be careful when setting the Transmit and Receive FIFO trigger threshold levels.

There are restrictions on how the DMA can be programmed when used with the SSP Controller.

- The DMA Transfer Width must be greater than or equal to the SSP data size. For example if the SSP Data Size is 16b then the DMA Transfer Width should be 16b.
- The DMA may not support the DMA Transfer Width of the SSP Data Size and therefore the DMA Transfer Width must be larger than the SSP Data Size. If this is the case then software must manage any extra data bits.
- The DMA Burst Transaction Length for RX must be less than or equal to the RX Threshold.
- The DMA Burst Transaction Length for TX must be less than or equal to the number of empty locations in the TX FIFO. A safe value is the Total TX FIFO Size - TX Threshold.
- DMA must be in Fixed Address mode to read or write the SSP Data Register.

In full-duplex formats where the Enhanced SSP always receives the same number of data samples as it transmits, the DMA should be set up to transmit and receive the same number of bytes.

Note: A TFT value of 0 means that there is one sample left in the TX FIFO.

Because the Enhanced SSP is not flow controlled, software must program the TX FIFO Threshold (TFT), RX FIFO Threshold (RFT), and the DMA burst size to ensure that a TX FIFO overflow or RX FIFO underflow does not occur. Software must also ensure that the Enhanced SSP DMA requests are properly prioritized in the system to prevent fatal overruns and under-runs.

The programming model for using the DMA is as follows:

- Program the total number of Transmit/Receive byte lengths, DMA burst, and DMA Width in the DMA.
- Set the preferred values in the Enhanced SSP Control registers.
- Enable the Enhanced SSP by setting SSCR0.SSE.
- Set the run bit in DMA Command Register.

- The DMA will wait for either the Transmit or Receive Service requests.
- If the Transmit/Receive byte length is not an even multiple of the transfer burst size, a trailing byte condition may occur.

21.7.2 Trailing Bytes in the Receive FIFO

When the number of samples in the Receive FIFO is less than its FIFO trigger threshold level, and no additional data is received, the remaining bytes are called trailing bytes. Trailing bytes can be handled by either the DMA or the processor, as indicated by the SSCR1.TRAIL bit. Trailing bytes are identified by means of a timeout mechanism and the existence of data within the Receive FIFO.

21.7.2.1 Timeout

A timeout condition exists when the Receive FIFO has been idle for a period of time (in APB clocks) defined by the value programmed within the Timeout register (SSTO). When a timeout occurs, the receiver timeout interrupt SSSR.TINT bit will be set to a 1, and if the Timeout Interrupt is enabled SSCR1.TINTE=1, a Timeout Interrupt will occur to signal the processor that a timeout condition has occurred. The timeout timer is reset after a new sample is received. Once the SSSR.TINT bit is set it must be cleared by software by writing a 1 to it. Clearing this bit also causes the Timeout Interrupt, if enabled, to be de-asserted.

21.7.2.2 Peripheral Trailing Byte Interrupt

It is possible for the DMA to reach the end of its Descriptor chain while removing Receive FIFO data. When this happens, the processor is forced to take over because the DMA can no longer service the Enhanced SSP request until a new chain is linked. When the DMA has reached the end of its Descriptor chain, and there is data in the receive FIFO, the Enhanced SSP will do the following:

- Sets the peripheral trailing byte interrupt SSSR.PINT bit to 1
- Asserts the Enhanced SSP Interrupt to signal to the processor that a Peripheral Trailing Byte Interrupt condition has occurred (if SSCR1.PINTE=1 to enable the interrupt).
- Sets the SSSR.EOC status bit which must be cleared by software. If more data is received after the EOC bit was set (and EOC bit is still set), then the SSSR.PINT bit will be set to a 1.

Once the SSSR.PINT bit is set, it must be cleared by software by writing a 1 to it. Clearing the SSSR.PINT bit also de-asserts the Peripheral Interrupt if it has been enabled (SSCR1.PINTE=1).

The remaining bytes must then be removed by means of a processor I/O as described in the processor-based method below, or by reprogramming a new Descriptor chain and restarting the DMA. Programmers need to be aware of this possibility. Refer to the DMA chapter for details on Descriptor programming and “end of chain” events.

21.7.2.3 Removing Trailing Bytes (Processor Based SSCR1.TRAIL=0)

This is the default method indicated by a zero in the SSCR1.TRAIL bit. In this case, no Receive DMA service request is generated. To read out the trailing bytes, software should wait for the timeout Interrupt and then read all remaining entries as indicated by the SSSR.RFL and SSSR.RNE bits within the Enhanced SSP Status register (SSSR).

Note: To use the Trailing bytes feature through the CPU, the Timeout Interrupt must be enabled by setting SSCR1.TINTE=1 (to enable the interrupt).

21.7.2.4 Removing Trailing Bytes (DMA Based SSCR1.TRAIL=1)

When the DMA is to handle trailing bytes (SSCR1.TRAIL = 1) a DMA service request is automatically issued for the remaining number of samples left in the Receive buffer. The DMA will then empty the contents of the Receive buffer unless the DMA reaches the end of its Descriptor chain. If a timeout occurs, the processor is only interrupted by means of a Timeout Interrupt if it has been enabled by setting SSCR1.TINTE=1. When handling trailing bytes by means of the DMA, if a timeout occurs and the receive FIFO is empty, an End-of-Receive (EOR) will be sent to the DMA Controller. If an EOC occurs at the time that the last sample is read out of the FIFO (the DMA descriptor chain was just exactly long enough), and the timeout counter is still running (that is, a time out has not occurred and the SSTS register is non-zero), then, when the time out does occur, the Enhanced SSP will generate a DMA request which will create an RAS interrupt from the DMA. When this occurs, software must re-program the DMA registers and re-enable the channel for the Enhanced SSP to send its EOR to the DMA controller.

21.11.7 reg_IMRD_type (IMRD)—Offset 30h

IMRD

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

IMRD: [BAR + 140000h] + 30h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Description
62	0b RW	LPE_IA_DONE: Done. When the bit is set, the LPE completed the operation and requests attention
61:0	000000000 00000000h RW	IA_LPE_MSG: IA-32 to LPE Message

21.11.9 reg_IPCD_type (IPCD)—Offset 40h

Inter-process Status and Message register for LPE contains a message sent from LPE to IA-32 CPU. The format of the CPU message bits 29:0 is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When software writes the message is in this register, it should set bit 63 to indicate that the new data is written. When IA-32 CPU reads the message code from the register, and writes back with the bit 63 cleared. When the IA-32 CPU processes the message sent by LPE, it may set bit 63 in IPCD to assert interrupt request to LPE. The LPE must not attempt to write into IPCLPEIA if bit 63 is set.

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

IPCD: [BAR + 140000h] + 40h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Description
63	0b RW	LPE_IA_BUSY: Busy. When this bit is cleared, the IA CPU is Ready to accept a new message
62	0b RW	IA_LPE_DONE: Done. When the bit is set, the IA CPU completed operation and requests attention from LPE
61:0	000000000 00000000h RW	LPE_IA_MSG: LPE to IA CPU Message

21.11.10 reg_ISRSC_type (ISRSC)—Offset 48h

ISRSC

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

ISRSC: [BAR + 140000h] + 48h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Description
63:34	0b RO	RSVD0: Reserved
33	0b RW/1C	Wake_SCU_Status: This bit is set by hardware when a blocked transaction is detected. It generates a wake to the SCU
32	0b RW/1C	GoS0ixInt_SCU_Status: This bit is set by expiry of the Re-entry timer. The bit gets set only if GoS0ixInt_En bit is set and this interrupt is unmasked.
31:2	0b RO	RSVD1: Reserved
1	0b RO	LPE_SC_IPC_Request_Status: IPCLPESC Interrupt Request 1: interrupt when LPE writes a message into IPCLPESC register with bit 63 set 0: Deasserted
0	0b RW/1C	LPE_SC_IPC_Done_Status: IPCSC Interrupt Request 1: interrupt when LPE writes a message into IPCSC register with bit 62 set is asserted 0: Deasserted.

21.11.11 reg_ISRLPESC_type (ISRLPESC)—Offset 50h

ISRLPESC

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

ISRLPESC: [BAR + 140000h] + 50h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0000000000000000h

21.11.12 reg_IMRSC_type (IMRSC)—Offset 58h

IMRSC

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

IMRSC: [BAR + 140000h] + 58h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Description
63:35	0b RO	RSVD0: Reserved
34	0b RW/1C	GoS0ix_IntEn: This bit indicates that Reentry to S0iX interrupts to SCU are enabled. The bit is set by hardware when a transaction is blocked at the Audio to Secondary interface due to the secondary fabric being gated and the fabdisable bit being set. Software is expected to clear this bit along with the Secondary Fabric Reject bit. This disables the interrupts.
33	0b RW	FabDisable: This bit is used to generate the wake interrupt to SCU. When set the interrupt generation is enabled. When cleared the interrupt generation is disabled
32	0b RW	GoS0ixInt_SCU_Mask: Mask bit for S0ix Reentry interrupt to SCU
31:2	0b RO	RSVD1: Reserved
1	0b RW	LPE_SC_IPC_Request_Mask: IPCLPESC Interrupt Enable to SC CPU
0	0b RW	LPE_SC_IPC_Done_Mask: IPCSC Interrupt Enable to SC CPU

21.11.13 reg_IMRLPESC_type (IMRLPESC)—Offset 60h

IMRLPESC

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

IMRLPESC: [BAR + 140000h] + 60h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Description
63:2	0b RO	RSVD0: Reserved
1	0b RW	SC_LPE_IPC_Request_Mask: IPCSC interrupt Enable to LPE
0	0b RW	SC_LPE_IPC_Done_Mask: IPCLPESC interrupt Enable to LPE

21.11.14 reg_IPCSC_type (IPCSC)—Offset 68h

The Inter-process Status and Message register for SC contains a message sent from the SC CPU to LPE. The format of the CPU message bits (29:0) is not defined in the HW specs. It is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When the message is written in this register, the software must set bit 63 to indicate that the IPCSC is not empty. Setting Busy also asserts interrupt request to LPE if the interrupt is enabled in the IMRLPESC. After LPE reads the message code from the register, it must perform a write with bit 63 cleared. The SC CPU must not attempt to write into IPCIA if bit 63 is set.

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

IPCSC: [BAR + 140000h] + 68h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Description
63	0b RW	SC_LPE_BUSY: Busy. When this bit is cleared, the LPE Ready to accept a message
62	0b RW	LPE_SC_DONE: Done. When the bit is set, the LPE completed the operation and requests attention
61:0	00000000 0000000h RW	SC_LPE_MSG: SC to LPE Message

21.11.15 reg_IPCLPESC_type (IPCLPESC)—Offset 70h

Inter-process Status and Message register for LPE contains a message sent from LPE to SC. The format of the CPU message bits 29:0 is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When software writes the message is in this register, it should set bit 63 to indicate that the new data is written. When SC reads the message code from the register, and writes back with the bit 63 cleared. When the SC CPU processes the message sent by LPE, it may set bit 62 in IPCLPESC to assert interrupt request to LPE. The LPE must not attempt to write into IPCD if bit 63 is set.

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

IPCLPESC: [BAR + 140000h] + 70h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Description
63	0b RW	LPE_SC_BUSY: Busy. When this bit is cleared, the SC CPU is Ready to accept a new message
62	0b RW	SC_LPE_DONE: Done. When the bit is set, the SC CPU completed operation and requests attention from LPE
61:0	0h RW	LPE_SC_MSG: LPE to SC CPU Message

21.11.16 reg_CLKCTL_type (CLKCTL)—Offset 78h

LPE Clock Control Register

Access Method

Bit Range	Default & Access	Description
0	0b RW	PSH_LPE_IPC_Done_Mask: IPCLPEPSH interrupt Enable to LPE

21.11.23 reg_IPCPSH_type (IPCPSH)—Offset B0h

The Inter-process Status and Message register for PSH contains a message sent from the PSH CPU to LPE. The format of the CPU message bits (29:0) is not defined in the HW specs. It is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When the message is written in this register, the software must set bit 63 to indicate that the IPCPSH is not empty. Setting Busy also asserts interrupt request to LPE if the interrupt is enabled in the IMRLPEPSH. After LPE reads the message code from the register, it must perform a write with bit 63 cleared. The PSH CPU must not attempt to write into IPCIA if bit 63 is set.

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

IPCPSH: [BAR + 140000h] + B0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0000000000000000h

Bit Range	Default & Access	Description
63	0b RW	PSH_LPE_BUSY: Busy. When this bit is cleared, the LPE Ready to accept a message
62	0b RW	LPE_PSH_DONE: Done. When the bit is set, the LPE completed the operation and requests attention
61:0	00000000 0000000h RW	PSH_LPE_MSG: PSH to LPE Message

21.11.24 reg_IPCLPEPSH_type (IPCLPEPSH)—Offset B8h

Inter-process Status and Message register for LPE contains a message sent from LPE to PSH. The format of the CPU message bits 29:0 is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When software writes the message is in this register, it should set bit 63 to indicate that the new data is written. When PSH reads the message code from the register, and writes back with the bit 63 cleared. When the PSH CPU processes the message sent by LPE, it may set bit 62 in IPCLPEPSH to assert interrupt request to LPE. The LPE must not attempt to write into IPCD if bit 63 is set.

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

IPCLPEPSH: [BAR + 140000h] + B8h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Bit Range	Default & Access	Description
63	0b RW	LPE_PSH_BUSY: Busy. When this bit is cleared, the PSH CPU is Ready to accept a new message
62	0b RW	PSH_LPE_DONE: Done. When the bit is set, the PSH CPU completed operation and requests attention from LPE
61:0	0h RW	LPE_PSH_MSG: LPE to PSH CPU Message

21.11.25 reg_EXT_TIMER_CNTL_type (EXT_TIMER_CNTL)—Offset C0h

External Timer Control Register

Access Method

Type: Memory Mapped I/O Register
(Size: 64 bits)

EXT_TIMER_CNTL: [BAR + 140000h] + C0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0000000000000000h

63	60	56	52	48	44	40	36	32	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Ext_Timer_Run Ext_Timer_Clear RSVD0 Ext_Timer_Matchvalue																

Bit Range	Default & Access	Description
63	0b RW	Ext_Timer_Run: Timer Run bit. The timer runs only when this bit is set. It resumes running from the current value in the readvalue bits. Clearing the bit pauses the timer.
62	0b RW/S	Ext_Timer_Clear: Timer Clear bit. Clears the timer and sets the value back to zero. This should also be reflected in the readvalue bits

Bit Range	Default & Access	Description
61:32	0b RO	RSVD0: Reserved
31:0	0b RW	Ext_Timer_Matchvalue: The timer will generate a pulse when the Readvalue reaches Matchvalue. The pulse causes a level interrupt to get set in the PISR register. The PISR interrupt needs to be cleared before the next pulse is generated. The timer keeps counting beyond the Readvalue. Setting the Matchvalue to zero makes this a free running timer and no interrupt will be generated in this case. For correct operation, the ISR should either set a new Matchvalue or set it to zero. If nothing is done, the timer will roll over and trigger an interrupt again when it reaches the Matchvalue.

21.12.1 SSP Control 0 Register (SSCR0)—Offset 0h

The Enhanced SSP Control 0 registers contain twelve different bit fields that control various functions within the Enhanced SSP. All bits must be set to the preferred value before enabling the Enhanced SSP. Note that Writes to reserved bits must be zeroes, and Read values of these bits is undetermined.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR0: [BAR + 0A0000h] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

Bit Range	Default & Access	Description
31	0b RW	Mode Select (MOD): 0 = Normal SSP Mode 1 = Network Mode
30	0b RW	Audio Clock Select (ACS): 0 = Clock selection is determined by the NCS and ECS bits 1 = Audio Clock (and Audio Clock Divider) are used to clock the SSP's serial clock (SSPCLK)
29	0b RO	Reserved (RSVD): Reserved.
28	0b RO	Reserved (RSVD): Reserved.
27	0b RO	Reserved (RSVD): Reserved.
26:24	000b RW	Frame Rate Divider Control (FRDC): Value 0-7 indicates the number of time slots per frame when in network mode (the actual number of time slots is FRDC+1, so 1 to 8 time slots).
23	0b RW	Transmit FIFO Under Run Interrupt Mask (TIM): 0 = TUR events will generate an SSP interrupt 1 = TUR events will not generate an SSP interrupt
22	0b RW	Receive FIFO Over Run Interrupt Mask (RIM): 0 = ROR events will generate an SSP interrupt 1 = ROR events will not generate an SSP interrupt
21	0b RW	Network Clock Select (NCS): 0 = Clock selection is determined by ECS bit 1 = Network clock is used to create the SSP's serial clock (SSPCLK)
20	0b RW	Extended Data Size Select (EDSS): 0 = A zero is preappended to the DSS value which sets the DSS range from 4-16 bits 1 = A one is pre-appended to the DSS value which sets the DSS range from 17-32 bits
19:8	000h RW	Serial Clock Rate (SCR): Value (0 to 4095) used to generate transmission rate of SSP. Serial bit rate = SSP clock/(SCR+1), where SCR is decimal integer.
7	0b RW	Synchronous Serial Port Enable (SSE): 0 = SSP operation disabled and FIFOs are cleared 1 = SSP operation enabled
6	0b RW	External Clock Select (ECS): 0 = On-chip clock used to produce the SSP's serial clock (SSPCLK) 1 = SSPEXTCLK/GPIO pin is used to create the SSP's SSPCLK
5:4	00b RW	Frame Format (FRF): 00 = Motorola Serial Peripheral Interface (SPI) 01 = Texas Instruments Synchronous Serial Protocol (SSP) 10 = National Semiconductor Microwire 11 = Programmable Serial Protocol (PSP)
3:0	0000b RW	Data Size Select (DSS): With EDSS as MSB, value+1 gives data size. Values 4 to 32 allowed.

21.12.2 SSP Control 1 Register (SSCR1)—Offset 4h

The Enhanced SSP Control 1 registers contain bit fields that control various SSP functions. Bits must be set to the preferred value before enabling the Enhanced SSP. Note that Writes to reserved bits should be zeroes, and Read value of these bits are undetermined.

Access Method

17	0b RW	RSVD: Reserved
16	0b RW	Invert Frame Signal (IFS): 0 = Frame polarity is determined by SSP format and PSP polarity bits 1 = Frame signal will be inverted from the normal SSP frame signal (as defined by the SSP format nad PSP polarity bits)

Bit Range	Default & Access	Description
15	0b RW	Select FIFO for EFWR (test mode bit) (when EFWR=1) (STRF): 0 = Transmit FIFO is selected for both writes and reads through the SSP Data Register (SSDR) 1 = Receive FIFO is selected for both writes and reads through the SSP Data Register (SSDR)
14	0b RW	Enable FIFO Write/Read (test mode bit) (EFWR): 0 = FIFO write/read special function is disabled (normal SSP operational mode) 1 = FIFO write/read special function is enabled
13:10	0000b RW	Receive FIFO Trigger Threshold (RFT): Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. This is a legacy field and only represents the lower 4b of the FIFO Trigger Threshold. Please see SFIFOTT register for complete threshold setting.
9:6	0000b RW	Transmit FIFO Trigger Threshold (TFT): Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. This is a legacy field and only represents the lower 4b of the FIFO Trigger Threshold. Please see SFIFOTT register for complete threshold setting.
5	0b RW	Microwire Transmit Data Size (MWDS): 0 = 8-bit command words are transmitted 1 = 16-bit command words are transmitted
4	0b RW	Motorola SPI SSPSCLK Phase Setting (SPH): 0 = SSPSCLK is inactive one cycle at the start of a frame and 1/2 cycle at the end of a frame 1 = SSPSCLK is inactive 1/2 cycle at the start of a frame and one cycle at the end of a frame
3	0b RW	Motorola SPI SSPSCLK polarity setting (SPO): 0 = The inactive or idle state of SSPSCLK is low 1 = The inactive or idle state of SSPSCLK is high
2	0b RW	Loop-Back Mode (test mode bit) (LBM): 0 = Normal serial port operation enabled 1 = Output of transmit serial shifter connected to input of receive serial shifter, internally
1	0b RW	Transmit FIFO Interrupt Enable (TIE): 0 = Transmit FIFO level interrupt is disabled 1 = Transmit FIFO level interrupt is enabled
0	0b RW	Receive FIFO Interrupt Enable (RIE): 0 = Receive FIFO level interrupt is disabled 1 = Receive FIFO level interrupt is enabled

21.12.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

Access Method

Default: 0000F004h

Bit Range	Default & Access	Description
1:0	00b RO	RSVD3: Reserved

21.12.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

4:0	00000b RO	RSVD2: Reserved

21.12.5 SSP Data Register (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the

register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

21.12.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values) and by the number of time slots being used (SSCR0.FRDC value), if any, to give the

SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined. It's important to note that this feature is only available if implemented by the project instantiation. A clock source and mux must be instantiated outside of the SSP controller for this feature to work. Only this register is designed into the SSP Controller.

Access Method

Type: Memory Mapped I/O Register

Underrun_fix_1	0	0	0	0	0	0	0	0									
Underrun_fix_0	0	0	0	0	0	0	0	0									

Bit Range	Default & Access	Description
31:12	0b RO	RSVD0: Reserved
11	0b RW	ASRC Interrupt Mask (ASRC_INTR_MASK): Setting this bit to 1 masks the ASRC interrupt that is generated every time the frame count matches the frame threshold. Software should override this bit, since it have no reset value
10	0b RW	ASRC frame count enable (ASRC_FRM_CNTR_EN): Setting this bit enables the frame counter to start running. Clearing this bit will make the frame counter go back to zero immediately.
9	0b RW/AC	ASRC Counter Clear (ASRC_CNTR_CLR): Setting this to 1 will clear the ASRC Free running counter. This bit will self clear after the counter is cleared.
8	0b RW	ASRC Counter enable (ASRC_CNTR_EN): Setting this bit makes the Free running ASRC counter to start running. Clearing this bit will make it pause and hold it's current value.
7	1b RW	Fifo empty fix enable (FIFO_EMPTY_FIX_EN): Corner cases between the FIFO empty and APB writes happening to the TX FIFO around the time the new data needs to be sent out on the TXD are fixed with this bit.
6	1b RW	Underrun fix enable (UNDRN_FIX_EN): OSC to PLL switch along with underrun was causing unexpected behavior. This bit enables the fix for that bug.
5:4	00b RW	Reserved: This is a RW bit with no effect on IP behavior
3	0b RW	Clock Delay Enable (CLK_DEL_EN): When CLK_DEL_EN = 0, delay logic for capturing data from device is disabled. When CLK_DEL_EN = 1, delay logic for capturing data from device is delayed by half a period of the IO clock
2	0b RW	Slave Mode External Clock Run Enable (SLV_EXT_CLK_RUN_EN): When in Slave mode the receive state machine requires several clock edges (around 6) to properly sample incoming data. This bit enables a free running clock to the receive state machine before any data is received to properly sample the incoming data. 0 = Disable 1 = Enable
1	0b RW	Mode 1 Underrun Fix (Underrun_fix_1): Mode 1 of transmit underrun fix. In this mode, new data will start on the underrun slot. This function is only applied to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1 If both underrun modes are enable, mode 1 has higher priority.
0	0b RW	Mode 0 Underrun Fix (Underrun_fix_0): Mode 0 of transmit underrun fix. In this mode, new data will always start at slot 0. This function is only applied to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1

21.12.13 SSP Frame Select Register (SSFS)—Offset 44h

The SSP Frame select register is used to choose which frame signal to assert when accessing a slave device. SW drivers should set this register to assert the correct frame select to the targetted device.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSFS: [BAR + 0A0000h] + 44h

BAR Type: PCI Configuration Register (Size: 32 bits)

0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
RFL				TFL				

Bit Range	Default & Access	Description
31:16	0000h RW	Receive FIFO Trigger Threshold (RFT): Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. Notes on setting the RFT value. This applies to cases where SSP is receiving data from a device and is interfaced with a DMA channel via the hardware handshake mechanism. Please follow the following recommendations: 1. Number of bits denoted by the (DSS, EDSS) parameters in the SSP should match the SRC_TR_WIDTH programmed in the DMA channel. 2. (RFT+1) should be equal to (SRC_MSIZ). 3. Another option to 2 is to keep the BLOCK_TS in the DMA to be a multiple of (RFT+1)
15:0	0000h RW	Transmit FIFO Trigger Threshold (TFT): Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1.

21.12.17 SSP Control 3 Register (SSCR3)—Offset 70h

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

Access Method

				RSVD				
				I2S_RX_SS_FIX_EN				
				I2S_TX_SS_FIX_EN				
				RSVD				
				I2S_MODE_EN				
				FRM_MST_EN				

Bit Range	Default & Access	Description
31:18	0b RO	RSVD0: Reserved
17	1b RW	Sync Fix Enable (SYN_FIX_EN): This is a chicken bit for enabling the synchronizer fix for clr_underrun_ssp signal. SW should preserve this bit at its default value.
16	0b RW	Master Mode Clock Enable (MST_CLK_EN): When in single slot master mode (which is the mode used for emulating I2S or LJ master mode), the SSP core can stop the clock on a Tx underflow condition, preventing the Rx side from receiving data. This bit, when set, forces the clock to run when a Tx underflow happens, thereby allowing Rx side to continue functioning while Tx side is in underflow. SW should set this bit when I2S or LJ master mode is enabled i.e. bits 0 and 1 in this register are both set or when using 1-slot PCM (SFS or LFS) master mode operation. Otherwise, SW should leave this at 0.
15	1b RW	Stretch RX Pulse (STRETCH_RX): HW uses this as a chicken bit to stretch the RX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.
14	1b RW	Stretch TX Pulse (STRETCH_TX): HW uses this as a chicken bit to stretch the TX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.

Bit Range	Default & Access	Description
13	0b RO	Reserved (RSVD): Reserved.
12	0b RO	Reserved (RSVD): Reserved.
11	0b RW	I2S VISA Enable (I2S_VISA_EN): Enables newly added I2S and PCM wrapper logic debug signals sent out on the VISA bus instead of the core SSP debug signals. 0 = Core SSP Debug Signals 1 = New I2S and PCM Debug Signals
10	1b RW	I2S Receive Enable (I2S_RX_EN): When set, this bit enables data to be received on both the left and right slots of I2S. Otherwise, data on the slots are ignored. HW does not signal FIFO full condition when this bit is cleared. SW can set/clear this bit dynamically when I2S mode is operational.
9	1b RW	I2S Transmit Enable (I2S_TX_EN): When set, this bit enables data to be transmitted on both the left and right slots of I2S. Otherwise, data on the slots are ignored. HW does not signal FIFO full condition when this bit is cleared. SW can set/clear this bit dynamically when I2S mode is operational.
8	0b RO	Reserved (RSVD): Reserved.
7:6	00b RO	Reserved (RSVD): Reserved.
5	0b RO	Reserved (RSVD): Reserved.
4	0b RW	I2S RX Slot Swap Fix Enable (I2S_RX_SS_FIX_EN): This bit enables the Rx overrun fix in I2S or LJ modes and prevents channel swapping when Rx overrun happens. Note that this bit does not apply to any PCM modes. PCM modes still have the Rx overflow channel aliasing issue, similar to PNW/CLV. SW should set this bit only when I2S or LJ mode (slave or master) is enabled. 0 = Disable 1 = Enable
3	0b RW	I2S TX Slot Swap Fix Enable (I2S_TX_SS_FIX_EN): This bit enables the TX underflow fix in I2S or LJ modes and prevents channel swapping when TX underflow happens. Note that this bit does not apply to any PCM modes. PCM modes still have the TX underflow channel aliasing issue, similar to PNW/CLV. SW should set this bit only when I2S or LJ mode (slave or master) is enabled. 0 = Disable 1 = Enable
2	1b RO	Reserved (RSVD): Reserved.
1	0b RW	I2S Mode Enable (I2S_MODE_EN): This bit enables I2S Mode. In I2S mode, slave or master mode operation is selected by appropriately clearing/setting bit 0 in this register. SW should select I2S mode operation before enabling the SSP controller. 0 = Disabled 1 = Enabled
0	0b RW	Frame Master Enable (FRM_MST_EN): When set, this bit enables the internal frame generator logic that allows accurate frame rate generation. This bit should be set for I2S and PCM master mode operations and cleared for all other modes. SW should select the proper value in this bit before enabling SSP controller. 0 = Disabled 1 = Enabled

21.12.18 SSP Control 4 Register (SSCR4)—Offset 74h

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

Access Method

21.13.1 SSP Control 0 Register (SSCR0)—Offset 0h

The Enhanced SSP Control 0 registers contain twelve different bit fields that control various functions within the Enhanced SSP. All bits must be set to the preferred value before enabling the Enhanced SSP. Note that Writes to reserved bits must be zeroes, and Read values of these bits is undetermined.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR0: [BAR + 0A1000h] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31					28					24					20					16					12					8					4					0																																							
0					0					0					0					0					0					0					0					0					0																																		
MOD					ACS					RSVD					RSVD					RSVD					FRDC					TIM					RIM					NCS					EDSS					SCR										SSE					ECS					FRF					DSS				

Bit Range	Default & Access	Description
31	0b RW	Mode Select (MOD): 0 = Normal SSP Mode 1 = Network Mode
30	0b RW	Audio Clock Select (ACS): 0 = Clock selection is determined by the NCS and ECS bits 1 = Audio Clock (and Audio Clock Divider) are used to clock the SSP's serial clock (SSPCLK)
29	0b RO	Reserved (RSVD): Reserved.
28	0b RO	Reserved (RSVD): Reserved.
27	0b RO	Reserved (RSVD): Reserved.
26:24	000b RW	Frame Rate Divider Control (FRDC): Value 0-7 indicates the number of time slots per frame when in network mode (the actual number of time slots is FRDC+1, so 1 to 8 time slots).
23	0b RW	Transmit FIFO Under Run Interrupt Mask (TIM): 0 = TUR events will generate an SSP interrupt 1 = TUR events will not generate an SSP interrupt
22	0b RW	Receive FIFO Over Run Interrupt Mask (RIM): 0 = ROR events will generate an SSP interrupt 1 = ROR events will not generate an SSP interrupt
21	0b RW	Network Clock Select (NCS): 0 = Clock selection is determined by ECS bit 1 = Network clock is used to create the SSP's serial clock (SSPCLK)
20	0b RW	Extended Data Size Select (EDSS): 0 = A zero is preappended to the DSS value which sets the DSS range from 4-16 bits 1 = A one is pre-appended to the DSS value which sets the DSS range from 17-32 bits
19:8	000h RW	Serial Clock Rate (SCR): Value (0 to 4095) used to generate transmission rate of SSP. Serial bit rate = SSP clock/(SCR+1), where SCR is decimal integer.
7	0b RW	Synchronous Serial Port Enable (SSE): 0 = SSP operation disabled and FIFOs are cleared 1 = SSP operation enabled
6	0b RW	External Clock Select (ECS): 0 = On-chip clock used to produce the SSP's serial clock (SSPCLK) 1 = SSPEXTCLK/GPIO pin is used to create the SSP's SSPCLK
5:4	00b RW	Frame Format (FRF): 00 = Motorola Serial Peripheral Interface (SPI) 01 = Texas Instruments Synchronous Serial Protocol (SSP) 10 = National Semiconductor Microwire 11 = Programmable Serial Protocol (PSP)
3:0	0000b RW	Data Size Select (DSS): With EDSS as MSB, value+1 gives data size. Values 4 to 32 allowed.

21.13.2 SSP Control 1 Register (SSCR1)—Offset 4h

The Enhanced SSP Control 1 registers contain bit fields that control various SSP functions. Bits must be set to the preferred value before enabling the Enhanced SSP. Note that Writes to reserved bits should be zeroes, and Read value of these bits are undetermined.

Access Method

19	0b RW	Receiver Time-out Interrupt Enable (TINTE): 0 = Receiver Time-out interrupts are disabled 1 = Receiver Time-out interrupts are enabled
18	0b RW	Peripheral Trailing Byte Interrupts Enable (PINTE): 0 = Peripheral Trailing Byte Interrupts are disabled 1 = Peripheral Trailing Byte Interrupts are enabled
17	0b RW	RSVD: Reserved
16	0b RW	Invert Frame Signal (IFS): 0 = Frame polarity is determined by SSP format and PSP polarity bits 1 = Frame signal will be inverted from the normal SSP frame signal (as defined by the SSP format nad PSP polarity bits)

Bit Range	Default & Access	Description
15	0b RW	Select FIFO for EFWR (test mode bit) (when EFWR=1) (STRF): 0 = Transmit FIFO is selected for both writes and reads through the SSP Data Register (SSDR) 1 = Receive FIFO is selected for both writes and reads through the SSP Data Register (SSDR)
14	0b RW	Enable FIFO Write/Read (test mode bit) (EFWR): 0 = FIFO write/read special function is disabled (normal SSP operational mode) 1 = FIFO write/read special function is enabled
13:10	0000b RW	Receive FIFO Trigger Threshold (RFT): Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. This is a legacy field and only represents the lower 4b of the FIFO Trigger Threshold. Please see SFIFOTT register for complete threshold setting.
9:6	0000b RW	Transmit FIFO Trigger Threshold (TFT): Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. This is a legacy field and only represents the lower 4b of the FIFO Trigger Threshold. Please see SFIFOTT register for complete threshold setting.
5	0b RW	Microwire Transmit Data Size (MWDS): 0 = 8-bit command words are transmitted 1 = 16-bit command words are transmitted
4	0b RW	Motorola SPI SSPSCLK Phase Setting (SPH): 0 = SSPSCLK is inactive one cycle at the start of a frame and 1/2 cycle at the end of a frame 1 = SSPSCLK is inactive 1/2 cycle at the start of a frame and one cycle at the end of a frame
3	0b RW	Motorola SPI SSPSCLK polarity setting (SPO): 0 = The inactive or idle state of SSPSCLK is low 1 = The inactive or idle state of SSPSCLK is high
2	0b RW	Loop-Back Mode (test mode bit) (LBM): 0 = Normal serial port operation enabled 1 = Output of transmit serial shifter connected to input of receive serial shifter, internally
1	0b RW	Transmit FIFO Interrupt Enable (TIE): 0 = Transmit FIFO level interrupt is disabled 1 = Transmit FIFO level interrupt is enabled
0	0b RW	Receive FIFO Interrupt Enable (RIE): 0 = Receive FIFO level interrupt is disabled 1 = Receive FIFO level interrupt is enabled

21.13.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

Access Method

Bit Range	Default & Access	Description
1:0	00b RO	RSVD3: Reserved

21.13.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

4:0	00000b RO	RSVD2: Reserved

21.13.5 SSP Data Register (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the

register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

RSVD

TTSA

Bit Range	Default & Access	Description
31:8	000000h RO	RSVD: Reserved
7:0	00h RW	TX Time Slot Active (TTSA): 0 = SSP will not transmit data in this time slot 1 = SSP will transmit data in this time slot

21.13.9 SSP RX Time Slot Active Register (SSRSA)—Offset 34h

The Enhanced SSP RX Time Slot Active registers are read-write registers that indicate which Time Slot the Enhanced SSP will receive data in and are ignored if the Enhanced SSP is not in Network Mode (SSCR0.MOD = 1). Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSRSA: [BAR + 0A1000h] + 34h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Intel Atom® Processor E3800 Product Family
Datasheet
2905

SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined. It's important to note that this feature is only available if implemented by the project instantiation. A clock source and mux must be instantiated outside of the SSP controller for this feature to work. Only this register is designed into the SSP Controller.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSACD: [BAR + 0A1000h] + 3Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

[illegible]

Bit Range	Default & Access	Description
31:7	0000000h RO	RSVD: Reserved
6:4	000b RW	Audio Clock PLL Select (ACPS): Value indicates which PLL output clock is sent to the clock divider in the clock unit 000: 5.622MHz, 001: 11.345MHz, 010: 12.235MHz, 011: 14.857MHz, 100: 32.842MHz, 101: 48.000MHz, 110, 111: Reserved
3	0b RW	SYSCLK Divider Bypass (SCDB): 0 = SYSCLK is divided by 4 before being sent to SSP 1 = SYSCLK is not divided before being sent to SSP
2:0	000b RW	Audio Clock Divider Select (ACDS): Value indicates which divider will be used by the clock unit to create the SYSCLK output pin. Clock divider value will be $2^{\wedge}ACDS$, max ACDS = 5.

21.13.12 SSP Control 2 Register (SSCR2)—Offset 40h

The command status register 2 is extension of command status register and contains various feature enable and disables.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR2: [BAR + 0A1000h] + 40h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 000000C0h

RSVD0																				ASRC_INTR_MASK															
																				ASRC_FRM_CNTR_EN															
																				ASRC_CNTR_CLR															
																				ASRC_CNTR_EN															
																				FIFO_EMPTY_FIX_EN															
																				UNDRN_FIX_EN															
																				Reserved															
																CLK_DEL_EN																			
																				SLV_EXT_CLK_RUN_EN															
																								Underrun_fix_1											
																												Underrun_fix_0							

Bit Range	Default & Access	Description
31:12	0b RO	RSVD0: Reserved
11	0b RW	ASRC Interrupt Mask (ASRC_INTR_MASK): Setting this bit to 1 masks the ASRC interrupt that is generated every time the frame count matches the frame threshold. Software should override this bit, since it have no reset value
10	0b RW	ASRC frame count enable (ASRC_FRM_CNTR_EN): Setting this bit enables the frame counter to start running. Clearing this bit will make the frame counter go back to zero immediately.
9	0b RW/AC	ASRC Counter Clear (ASRC_CNTR_CLR): Setting this to 1 will clear the ASRC Free running counter. This bit will self clear after the counter is cleared.
8	0b RW	ASRC Counter enable (ASRC_CNTR_EN): Setting this bit makes the Free running ASRC counter to start running. Clearing this bit will make it pause and hold it's current value.
7	1b RW	Fifo empty fix enable (FIFO_EMPTY_FIX_EN): Corner cases between the FIFO empty and APB writes happening to the TX FIFO around the time the new data needs to be sent out on the TXD are fixed with this bit.
6	1b RW	Underrun fix enable (UNDRN_FIX_EN): OSC to PLL switch along with underrun was causing unexpected behavior. This bit enables the fix for that bug.
5:4	00b RW	Reserved: This is a RW bit with no effect on IP behavior
3	0b RW	Clock Delay Enable (CLK_DEL_EN): When CLK_DEL_EN = 0, delay logic for capturing data from device is disabled. When CLK_DEL_EN = 1, delay logic for capturing data from device is delayed by half a period of the IO clock
2	0b RW	Slave Mode External Clock Run Enable (SLV_EXT_CLK_RUN_EN): When in Slave mode the receive state machine requires several clock edges (around 6) to properly sample incoming data. This bit enables a free running clock to the receive state machine before any data is received to properly sample the incoming data. 0 = Disable 1 = Enable
1	0b RW	Mode 1 Underrun Fix (Underrun_fix_1): Mode 1 of transmit underrun fix. In this mode, new data will start on the underrun slot. This function is only applied to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1 If both underrun modes are enable, mode 1 has higher priority.
0	0b RW	Mode 0 Underrun Fix (Underrun_fix_0): Mode 0 of transmit underrun fix. In this mode, new data will always start at slot 0. This function is only applied to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1

21.13.13 SSP Frame Select Register (SSFS)—Offset 44h

The SSP Frame select register is used to choose which frame signal to assert when accessing a slave device. SW drivers should set this register to assert the correct frame select to the targetted device.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSFS: [BAR + 0A1000h] + 44h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000001h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	1
RSVD0								FRAME_SEL

Bit Range	Default & Access	Description
31:4	0b RO	RSVD0: Reserved
3:0	0001b RW	Frame Select Enable (FRAME_SEL): Each bit in this field corresponds to a frame signal of the SSP Controller. Not all SSP controllers have all frame selects pinned out so consult the pin list for indication of which SSP controllers support how many frame signals. [Bit 0] Frame Select 0 Master and Slave Supported [Bit 1] Frame Select 1 Master Only [Bit 2] Frame Select 2 Master Only [Bit 3] Frame Select 3 Master Only 0 = Frame Select Disabled 1 = Frame Select Enabled

21.13.14 SSP Slot Frame Counter Register[0-7] (FRAME_CNT[0-7])—Offset 48h, Count 8, Stride 4h

The slot frame counter is typically used in Audio modes and increments the counter every two SSPCLKs. This allows the OS to check the progress of a transfer. Since the SSP can support upto 8 slots in network mode there are 8 slot frame counters.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

FRAME_CNT[0-7]: [BAR + 0A1000h] + 48h + [0-7]*4h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
FCNT_EN	RSVD0			FCNT_RST	FCNT			

Bit Range	Default & Access	Description
31	0b RW	Slot Frame Count Enable (FCNT_EN): 0 = Disable frame counter. 1 = Enable frame counter.
30:25	0b RO	RSVD0: Reserved
24	0b WO	Slot Frame Count Reset (FCNT_RST): SSP frame counter reset. Writing a 1 to this bit clears the frame counter.
23:0	000000h RO	Slot Frame Count (FCNT): SSP frame count.

21.13.15 SSP FIFO Level Register (SFIFOL)—Offset 68h

The SFIFOL register describes the current state of the RX and TX FIFOs. Not all bits of the TFL and RFL fields are used and depends on the actual hardware FIFO depth used in the instantiation of the SSP controller. This FIFO level register is meant to replace the SSSR.TFL and SSR.RFL fields.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SFIFOL: [BAR + 0A1000h] + 68h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: FFFF0000h

31	28	24	20	16	12	8	4	0
1	1	1	1	1	1	1	1	1
1	1	1	1	1	1	1	1	1
0	0	0	0	0	0	0	0	0
RFL				TFL				

Bit Range	Default & Access	Description
31:16	FFFFh RO	Receive FIFO Level (RFL): Number of entries minus one in Receive FIFO. Note: When the value of all 0xF's are read, the FIFO is either empty or full and the programmer should refer to the SSSR.RNE bit.
15:0	0000h RO	Transmit FIFO Level (TFL): Number of entries in Transmit FIFO. Note: When the value 0x0 is read, the FIFO is either empty or full and the programmer should refer to the SSSR.TNF bit.

21.13.16 SSP FIFO Trigger Threshold Register (SFIFOTT)—Offset 6Ch

The SFIFOTT is a register that determines when the the FIFOs will assert an interrupt for FIFO full indication. This is meant to replace the SSCR1.RFT and SSCR1.TFT legacy registers. The max size of these registers is based on the actualy FIFO depth in hardware and not the actual size of the bit field.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SFIFOTT: [BAR + 0A1000h] + 6Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
RFL				TFL				

Bit Range	Default & Access	Description
31:16	0000h RW	Receive FIFO Trigger Threshold (RFT): Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. Notes on setting the RFT value. This applies to cases where SSP is receiving data from a device and is interfaced with a DMA channel via the hardware handshake mechanism. Please follow the following recommendations: 1. Number of bits denoted by the (DSS, EDSS) parameters in the SSP should match the SRC_TR_WIDTH programmed in the DMA channel. 2. (RFT+1) should be equal to (SRC_MSIZ). 3. Another option to 2 is to keep the BLOCK_TS in the DMA to be a multiple of (RFT+1)
15:0	0000h RW	Transmit FIFO Trigger Threshold (TFT): Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1.

21.13.17 SSP Control 3 Register (SSCR3)—Offset 70h

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR3: [BAR + 0A1000h] + 70h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0002C604h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
				RSVD0

				RSVD				
				RSVD				
				RSVD				
				I2S_RX_SS_FIX_EN				
				I2S_TX_SS_FIX_EN				
				RSVD				
				I2S_MODE_EN				
				FRM_MST_EN				

Bit Range	Default & Access	Description
31:18	0b RO	RSVD0: Reserved
17	1b RW	Sync Fix Enable (SYN_FIX_EN): This is a chicken bit for enabling the synchronizer fix for clr_underrun_ssp signal. SW should preserve this bit at its default value.
16	0b RW	Master Mode Clock Enable (MST_CLK_EN): When in single slot master mode (which is the mode used for emulating I2S or LJ master mode), the SSP core can stop the clock on a Tx underflow condition, preventing the Rx side from receiving data. This bit, when set, forces the clock to run when a Tx underflow happens, thereby allowing Rx side to continue functioning while Tx side is in underflow. SW should set this bit when I2S or LJ master mode is enabled i.e. bits 0 and 1 in this register are both set or when using 1-slot PCM (SFS or LFS) master mode operation. Otherwise, SW should leave this at 0.
15	1b RW	Stretch RX Pulse (STRETCH_RX): HW uses this as a chicken bit to stretch the RX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.
14	1b RW	Stretch TX Pulse (STRETCH_TX): HW uses this as a chicken bit to stretch the TX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.

Bit Range	Default & Access	Description
13	0b RO	Reserved (RSVD): Reserved.
12	0b RO	Reserved (RSVD): Reserved.
11	0b RW	I2S VISA Enable (I2S_VISA_EN): Enables newly added I2S and PCM wrapper logic debug signals sent out on the VISA bus instead of the core SSP debug signals. 0 = Core SSP Debug Signals 1 = New I2S and PCM Debug Signals
10	1b RW	I2S Receive Enable (I2S_RX_EN): When set, this bit enables data to be received on both the left and right slots of I2S. Otherwise, data on the slots are ignored. HW does not signal FIFO full condition when this bit is cleared. SW can set/clear this bit dynamically when I2S mode is operational.
9	1b RW	I2S Transmit Enable (I2S_TX_EN): When set, this bit enables data to be transmitted on both the left and right slots of I2S. Otherwise, data on the slots are ignored. HW does not signal FIFO full condition when this bit is cleared. SW can set/clear this bit dynamically when I2S mode is operational.
8	0b RO	Reserved (RSVD): Reserved.
7:6	00b RO	Reserved (RSVD): Reserved.
5	0b RO	Reserved (RSVD): Reserved.
4	0b RW	I2S RX Slot Swap Fix Enable (I2S_RX_SS_FIX_EN): This bit enables the Rx overrun fix in I2S or LJ modes and prevents channel swapping when Rx overrun happens. Note that this bit does not apply to any PCM modes. PCM modes still have the Rx overflow channel aliasing issue, similar to PNW/CLV. SW should set this bit only when I2S or LJ mode (slave or master) is enabled. 0 = Disable 1 = Enable
3	0b RW	I2S TX Slot Swap Fix Enable (I2S_TX_SS_FIX_EN): This bit enables the TX underflow fix in I2S or LJ modes and prevents channel swapping when TX underflow happens. Note that this bit does not apply to any PCM modes. PCM modes still have the TX underflow channel aliasing issue, similar to PNW/CLV. SW should set this bit only when I2S or LJ mode (slave or master) is enabled. 0 = Disable 1 = Enable
2	1b RO	Reserved (RSVD): Reserved.
1	0b RW	I2S Mode Enable (I2S_MODE_EN): This bit enables I2S Mode. In I2S mode, slave or master mode operation is selected by appropriately clearing/setting bit 0 in this register. SW should select I2S mode operation before enabling the SSP controller. 0 = Disabled 1 = Enabled
0	0b RW	Frame Master Enable (FRM_MST_EN): When set, this bit enables the internal frame generator logic that allows accurate frame rate generation. This bit should be set for I2S and PCM master mode operations and cleared for all other modes. SW should select the proper value in this bit before enabling SSP controller. 0 = Disabled 1 = Enabled

21.13.18 SSP Control 4 Register (SSCR4)—Offset 74h

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR4: [BAR + 0A1000h] + 74h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Bit Range	Default & Access	Description
31:16	0b RO	RSVD0: Reserved
15:7	000h RW	Total Frame Period (TOT_FRM_PRD): The total frame period (both asserted and deasserted time of frame), measured in bit clocks, that is driven in I2S, LJ and PCM master modes. This can be controlled to get the desired accuracy on frame rate. A value of 0 and a value smaller than the value programmed in SSCR5.FrameAssertedWidth are illegal
6:0	00h RO	Reserved (RSVD): Reserved.

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR5: [BAR + 0A1000h] + 78h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:26	0b RO	RSVD0: Reserved
25:1	0000000h RW	Frame Assert Width (FRM_ASRT_WIDTH): This field controls the width of the asserted period of frame in I2S, LJ and PCM master modes. A value of 1 indicates a width of 2 bit clock period, 2 indicates a width of 3 bit clock periods, etc. The frame width is Frame Assert Width + 1.

Bit Range	Default & Access	Description
31:16	0b RO	RSVD0: Reserved
15:0	0000h RO	ASRC Frame Count (ASRC_FRM_COUNT): This is the current frame count. This is a debug register and the value is noted in this register only when the LSB of the frame counter flips. If the counter is cleared when it was at an even value, the cleared value is not reflected here.

21.14.1 SSP Control 0 Register (SSCR0)—Offset 0h

The Enhanced SSP Control 0 registers contain twelve different bit fields that control various functions within the Enhanced SSP. All bits must be set to the preferred value before enabling the Enhanced SSP. Note that Writes to reserved bits must be zeroes, and Read values of these bits is undetermined.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR0: [BAR + 0A2000h] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31					28					24					20					16					12					8					4					0																																		
0					0					0					0					0					0					0					0					0					0																													
MOD					ACS					RSVD					RSVD					RSVD					FRDC					TIM					RIM					NCS					EDSS					SCR					SSE					ECS					FRF					DSS				

Bit Range	Default & Access	Description
31	0b RW	Mode Select (MOD): 0 = Normal SSP Mode 1 = Network Mode
30	0b RW	Audio Clock Select (ACS): 0 = Clock selection is determined by the NCS and ECS bits 1 = Audio Clock (and Audio Clock Divider) are used to clock the SSP's serial clock (SSPCLK)
29	0b RO	Reserved (RSVD): Reserved.
28	0b RO	Reserved (RSVD): Reserved.
27	0b RO	Reserved (RSVD): Reserved.
26:24	000b RW	Frame Rate Divider Control (FRDC): Value 0-7 indicates the number of time slots per frame when in network mode (the actual number of time slots is FRDC+1, so 1 to 8 time slots).
23	0b RW	Transmit FIFO Under Run Interrupt Mask (TIM): 0 = TUR events will generate an SSP interrupt 1 = TUR events will not generate an SSP interrupt
22	0b RW	Receive FIFO Over Run Interrupt Mask (RIM): 0 = ROR events will generate an SSP interrupt 1 = ROR events will not generate an SSP interrupt
21	0b RW	Network Clock Select (NCS): 0 = Clock selection is determined by ECS bit 1 = Network clock is used to create the SSP's serial clock (SSPCLK)
20	0b RW	Extended Data Size Select (EDSS): 0 = A zero is preappended to the DSS value which sets the DSS range from 4-16 bits 1 = A one is pre-appended to the DSS value which sets the DSS range from 17-32 bits
19:8	000h RW	Serial Clock Rate (SCR): Value (0 to 4095) used to generate transmission rate of SSP. Serial bit rate = SSP clock/(SCR+1), where SCR is decimal integer.
7	0b RW	Synchronous Serial Port Enable (SSE): 0 = SSP operation disabled and FIFOs are cleared 1 = SSP operation enabled
6	0b RW	External Clock Select (ECS): 0 = On-chip clock used to produce the SSP's serial clock (SSPCLK) 1 = SSPEXTCLK/GPIO pin is used to create the SSP's SSPCLK
5:4	00b RW	Frame Format (FRF): 00 = Motorola Serial Peripheral Interface (SPI) 01 = Texas Instruments Synchronous Serial Protocol (SSP) 10 = National Semiconductor Microwire 11 = Programmable Serial Protocol (PSP)
3:0	0000b RW	Data Size Select (DSS): With EDSS as MSB, value+1 gives data size. Values 4 to 32 allowed.

21.14.2 SSP Control 1 Register (SSCR1)—Offset 4h

The Enhanced SSP Control 1 registers contain bit fields that control various SSP functions. Bits must be set to the preferred value before enabling the Enhanced SSP. Note that Writes to reserved bits should be zeroes, and Read value of these bits are undetermined.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR1: [BAR + 0A2000h] + 4h

Bit Range	Default & Access	Description
15	0b RW	Select FIFO for EFWR (test mode bit) (when EFWR=1) (STRF): 0 = Transmit FIFO is selected for both writes and reads through the SSP Data Register (SSDR) 1 = Receive FIFO is selected for both writes and reads through the SSP Data Register (SSDR)
14	0b RW	Enable FIFO Write/Read (test mode bit) (EFWR): 0 = FIFO write/read special function is disabled (normal SSP operational mode) 1 = FIFO write/read special function is enabled
13:10	0000b RW	Receive FIFO Trigger Threshold (RFT): Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. This is a legacy field and only represents the lower 4b of the FIFO Trigger Threshold. Please see SFIFOTT register for complete threshold setting.
9:6	0000b RW	Transmit FIFO Trigger Threshold (TFT): Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. This is a legacy field and only represents the lower 4b of the FIFO Trigger Threshold. Please see SFIFOTT register for complete threshold setting.
5	0b RW	Microwire Transmit Data Size (MWDS): 0 = 8-bit command words are transmitted 1 = 16-bit command words are transmitted
4	0b RW	Motorola SPI SSPSCLK Phase Setting (SPH): 0 = SSPSCLK is inactive one cycle at the start of a frame and 1/2 cycle at the end of a frame 1 = SSPSCLK is inactive 1/2 cycle at the start of a frame and one cycle at the end of a frame
3	0b RW	Motorola SPI SSPSCLK polarity setting (SPO): 0 = The inactive or idle state of SSPSCLK is low 1 = The inactive or idle state of SSPSCLK is high
2	0b RW	Loop-Back Mode (test mode bit) (LBM): 0 = Normal serial port operation enabled 1 = Output of transmit serial shifter connected to input of receive serial shifter, internally
1	0b RW	Transmit FIFO Interrupt Enable (TIE): 0 = Transmit FIFO level interrupt is disabled 1 = Transmit FIFO level interrupt is enabled
0	0b RW	Receive FIFO Interrupt Enable (RIE): 0 = Receive FIFO level interrupt is disabled 1 = Receive FIFO level interrupt is enabled

21.14.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

Access Method

Default: 0000F004h

Bit Range	Default & Access	Description
1:0	00b RO	RSVD3: Reserved

21.14.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

4:0	00000b RO	RSVD2: Reserved

21.14.5 SSP Data Register (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the

register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

2:0	000b RO	Time Slot Status (TSS): Value indicates which time slot is currently active

21.14.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values) and by the number of time slots being used (SSCR0.FRDC value), if any, to give the

SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined. It's important to note that this feature is only available if implemented by the project instantiation. A clock source and mux must be instantiated outside of the SSP controller for this feature to work. Only this register is designed into the SSP Controller.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSACD: [BAR + 0A2000h] + 3Ch

3	0b RW	SYSCLK Divider Bypass (SCDB): 0 = SYSCLK is divided by 4 before being sent to SSP 1 = SYSCLK is not divided before being sent to SSP
2:0	000b RW	Audio Clock Divider Select (ACDS): Value indicates which divider will be used by the clock unit to create the SYSCLK output pin. Clock divider value will be 2^{ACDS} , max ACDS = 5.

21.14.12 SSP Control 2 Register (SSCR2)—Offset 40h

The command status register 2 is extension of command status register and contains various feature enable and disables.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR2: [BAR + 0A2000h] + 40h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 000000C0h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RSVD0						ASRC_INTR_MASK	1	1
						ASRC_FRM_CNTR_EN	0	0
						ASRC_CNTR_CLR	0	0
						ASRC_CNTR_EN	0	0
						FIFO_EMPTY_FIX_EN	0	0
						UNDRN_FIX_EN	0	0
						Reserved		
						CLK_DEL_EN	0	0
						SLV_EXT_CLK_RUN_EN	0	0
						Underrun_fix_1	0	0
						Underrun_fix_0	0	0

Bit Range	Default & Access	Description
31:12	0b RO	RSVD0: Reserved
11	0b RW	ASRC Interrupt Mask (ASRC_INTR_MASK): Setting this bit to 1 masks the ASRC interrupt that is generated every time the frame count matches the frame threshold. Software should override this bit, since it have no reset value
10	0b RW	ASRC frame count enable (ASRC_FRM_CNTR_EN): Setting this bit enables the frame counter to start running. Clearing this bit will make the frame counter go back to zero immediately.
9	0b RW/AC	ASRC Counter Clear (ASRC_CNTR_CLR): Setting this to 1 will clear the ASRC Free running counter. This bit will self clear after the counter is cleared.
8	0b RW	ASRC Counter enable (ASRC_CNTR_EN): Setting this bit makes the Free running ASRC counter to start running. Clearing this bit will make it pause and hold it's current value.
7	1b RW	Fifo empty fix enable (FIFO_EMPTY_FIX_EN): Corner cases between the FIFO empty and APB writes happening to the TX FIFO around the time the new data needs to be sent out on the TXD are fixed with this bit.
6	1b RW	Underrun fix enable (UNDRN_FIX_EN): OSC to PLL switch along with underrun was causing unexpected behavior. This bit enables the fix for that bug.
5:4	00b RW	Reserved: This is a RW bit with no effect on IP behavior
3	0b RW	Clock Delay Enable (CLK_DEL_EN): When CLK_DEL_EN = 0, delay logic for capturing data from device is disabled. When CLK_DEL_EN = 1, delay logic for capturing data from device is delayed by half a period of the IO clock
2	0b RW	Slave Mode External Clock Run Enable (SLV_EXT_CLK_RUN_EN): When in Slave mode the receive state machine requires several clock edges (around 6) to properly sample incoming data. This bit enables a free running clock to the receive state machine before any data is received to properly sample the incoming data. 0 = Disable 1 = Enable
1	0b RW	Mode 1 Underrun Fix (Underrun_fix_1): Mode 1 of transmit underrun fix. In this mode, new data will start on the underrun slot. This function is only applied to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1 If both underrun modes are enable, mode 1 has higher priority.
0	0b RW	Mode 0 Underrun Fix (Underrun_fix_0): Mode 0 of transmit underrun fix. In this mode, new data will always start at slot 0. This function is only applied to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1

21.14.13 SSP Frame Select Register (SSFS)—Offset 44h

The SSP Frame select register is used to choose which frame signal to assert when accessing a slave device. SW drivers should set this register to assert the correct frame select to the targetted device.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Bit Range	Default & Access	Description
31:16	FFFFh RO	Receive FIFO Level (RFL): Number of entries minus one in Receive FIFO. Note: When the value of all 0xF's are read, the FIFO is either empty or full and the programmer should refer to the SSSR.RNE bit.
15:0	0000h RO	Transmit FIFO Level (TFL): Number of entries in Transmit FIFO. Note: When the value 0x0 is read, the FIFO is either empty or full and the programmer should refer to the SSSR.TNF bit.

21.14.16 SSP FIFO Trigger Threshold Register (SFIFOTT)—Offset 6Ch

The SFIFOTT is a register that determines when the the FIFOs will assert an interrupt for FIFO full indication. This is meant to replace the SSCR1.RFT and SSCR1.TFT legacy registers. The max size of these registers is based on the actualy FIFO depth in hardware and not the actual size of the bit field.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SFIFOTT: [BAR + 0A2000h] + 6Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
RFL				TFL				

Bit Range	Default & Access	Description
31:16	0000h RW	Receive FIFO Trigger Threshold (RFT): Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. Notes on setting the RFT value. This applies to cases where SSP is receiving data from a device and is interfaced with a DMA channel via the hardware handshake mechanism. Please follow the following recommendations: 1. Number of bits denoted by the (DSS, EDSS) parameters in the SSP should match the SRC_TR_WIDTH programmed in the DMA channel. 2. (RFT+1) should be equal to (SRC_MSIZ). 3. Another option to 2 is to keep the BLOCK_TS in the DMA to be a multiple of (RFT+1)
15:0	0000h RW	Transmit FIFO Trigger Threshold (TFT): Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1.

21.14.17 SSP Control 3 Register (SSCR3)—Offset 70h

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR3: [BAR + 0A2000h] + 70h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0002C604h

Bit Range	Default & Access	Description
31:18	0b RO	RSVD0: Reserved
17	1b RW	Sync Fix Enable (SYN_FIX_EN): This is a chicken bit for enabling the synchronizer fix for clr_underrun_ssp signal. SW should preserve this bit at its default value.
16	0b RW	Master Mode Clock Enable (MST_CLK_EN): When in single slot master mode (which is the mode used for emulating I2S or LJ master mode), the SSP core can stop the clock on a Tx underflow condition, preventing the Rx side from receiving data. This bit, when set, forces the clock to run when a Tx underflow happens, thereby allowing Rx side to continue functioning while Tx side is in underflow. SW should set this bit when I2S or LJ master mode is enabled i.e. bits 0 and 1 in this register are both set or when using 1-slot PCM (SFS or LFS) master mode operation. Otherwise, SW should leave this at 0.
15	1b RW	Stretch RX Pulse (STRETCH_RX): HW uses this as a chicken bit to stretch the RX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.
14	1b RW	Stretch TX Pulse (STRETCH_TX): HW uses this as a chicken bit to stretch the TX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.

Bit Range	Default & Access	Description
13	0b RO	Reserved (RSVD): Reserved.
12	0b RO	Reserved (RSVD): Reserved.
11	0b RW	I2S VISA Enable (I2S_VISA_EN): Enables newly added I2S and PCM wrapper logic debug signals sent out on the VISA bus instead of the core SSP debug signals. 0 = Core SSP Debug Signals 1 = New I2S and PCM Debug Signals
10	1b RW	I2S Receive Enable (I2S_RX_EN): When set, this bit enables data to be received on both the left and right slots of I2S. Otherwise, data on the slots are ignored. HW does not signal FIFO full condition when this bit is cleared. SW can set/clear this bit dynamically when I2S mode is operational.
9	1b RW	I2S Transmit Enable (I2S_TX_EN): When set, this bit enables data to be transmitted on both the left and right slots of I2S. Otherwise, data on the slots are ignored. HW does not signal FIFO full condition when this bit is cleared. SW can set/clear this bit dynamically when I2S mode is operational.
8	0b RO	Reserved (RSVD): Reserved.
7:6	00b RO	Reserved (RSVD): Reserved.
5	0b RO	Reserved (RSVD): Reserved.
4	0b RW	I2S RX Slot Swap Fix Enable (I2S_RX_SS_FIX_EN): This bit enables the Rx overrun fix in I2S or LJ modes and prevents channel swapping when Rx overrun happens. Note that this bit does not apply to any PCM modes. PCM modes still have the Rx overflow channel aliasing issue, similar to PNW/CLV. SW should set this bit only when I2S or LJ mode (slave or master) is enabled. 0 = Disable 1 = Enable
3	0b RW	I2S TX Slot Swap Fix Enable (I2S_TX_SS_FIX_EN): This bit enables the TX underflow fix in I2S or LJ modes and prevents channel swapping when TX underflow happens. Note that this bit does not apply to any PCM modes. PCM modes still have the TX underflow channel aliasing issue, similar to PNW/CLV. SW should set this bit only when I2S or LJ mode (slave or master) is enabled. 0 = Disable 1 = Enable
2	1b RO	Reserved (RSVD): Reserved.
1	0b RW	I2S Mode Enable (I2S_MODE_EN): This bit enables I2S Mode. In I2S mode, slave or master mode operation is selected by appropriately clearing/setting bit 0 in this register. SW should select I2S mode operation before enabling the SSP controller. 0 = Disabled 1 = Enabled
0	0b RW	Frame Master Enable (FRM_MST_EN): When set, this bit enables the internal frame generator logic that allows accurate frame rate generation. This bit should be set for I2S and PCM master mode operations and cleared for all other modes. SW should select the proper value in this bit before enabling SSP controller. 0 = Disabled 1 = Enabled

21.14.18 SSP Control 4 Register (SSCR4)—Offset 74h

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR4: [BAR + 0A2000h] + 74h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Bit Range	Default & Access	Description
31:16	0b RO	RSVD0: Reserved
15:7	000h RW	Total Frame Period (TOT_FRM_PRD): The total frame period (both asserted and de-asserted time of frame), measured in bit clocks, that is driven in I2S, LJ and PCM master modes. This can be controlled to get the desired accuracy on frame rate. A value of 0 and a value smaller than the value programmed in SSCR5.FrameAssertedWidth are illegal
6:0	00h RO	Reserved (RSVD): Reserved.

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSCR5: [BAR + 0A2000h] + 78h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:26	0b RO	RSVD0: Reserved
25:1	0000000h RW	Frame Assert Width (FRM_ASRT_WIDTH): This field controls the width of the asserted period of frame in I2S, LJ and PCM master modes. A value of 1 indicates a width of 2 bit clock period, 2 indicates a width of 3 bit clock periods, etc. The frame width is Frame Assert Width + 1.

Bit Range	Default & Access	Description
31:16	0b RO	RSVD0: Reserved
15:0	0000h RO	ASRC Frame Count (ASRC_FRM_COUNT): This is the current frame count. This is a debug register and the value is noted in this register only when the LSB of the frame counter flips. If the counter is cleared when it was at an even value, the cleared value is not reflected here.

21.15.1 reg_SAR_type (SAR0)—Offset 0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAR0: [BAR + 98000h] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

Type: Memory Mapped I/O Register
(Size: 32 bits)

DAR0: [BAR + 98000h] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0

DAR								

21.15.4 reg_CTL_LO_type (CTL_LO0)—Offset 18h

This register contains fields that control the DMA transfer. The CTL_LO register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_LO0: [BAR + 98000h] + 18h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31				28				24				20				16				12				8				4				0																																			
0				0				0				0				0				0				0				0				0																																			
RSVD				LLP_SRC_EN				LLP_DST_EN				RSVD1				TT_FC				RSVD2				DST_SCATTER_EN				SRC_GATHER_EN				SRC_MSIZE				DEST_MSIZE				SINC				RSVD3				DINC				RSVD4				SRC_TR_WIDTH				DST_TR_WIDTH				INT_EN			

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZE: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZE: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.15.5 reg_CTL_HI_type (CTL_HI0)—Offset 1Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI0: [BAR + 98000h] + 1Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.15.6 reg_SSTAT_type (SSTAT0)—Offset 20h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTAT0: [BAR + 98000h] + 20h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

0	0	0	0	0	0	0	0	0

SSTAT

Bit Range	Default & Access	Description
31:0	0h RW	SSTAT: Source status information retrieved by hardware from the address pointed to by the contents of the Source Status Address Register. This register is a temporary placeholder for the source status information on its way to the SSTATn register location of the LLI. The source status information should be retrieved by software from the SSTATn register location of the LLI, and not by a read of this register over the DMA slave interface.

21.15.7 reg_DSTAT_type (DSTAT0)—Offset 28h

After the completion of each block transfer, hardware can retrieve the destination status information from the address pointed to by the contents of the DSTATARx register. This status information is then stored in the DSTATx register and written out to the DSTATx register location of the LLI. Note : This register is a temporary placeholder for the destination status information on its way to the DSTATx register location of the LLI. The destination status information should be retrieved by software from the DSTATx register location of the LLI and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

DSTAT0: [BAR + 98000h] + 28h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

0	0	0	0	0	0	0	0	0

DSTAT

Bit Range	Default & Access	Description
31:0	0h RW	DSTAT: Destination status information retrieved by hardware from the address pointed to by the contents of the Destination Status Address Register. This register is a temporary placeholder for the destination status information on its way to the DSTATn register location of the LLI. The destination status information should be retrieved by software from the DSTATn register location of the LLI and not by a read of this register over the DMA slave interface.

21.15.8 reg_SSTATAR_type (SSTATAR0)—Offset 30h

After the completion of each block transfer, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTATAR0: [BAR + 98000h] + 30h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	SSTATAR: Pointer from where hardware can fetch the source status information, which is registered in the SSTATn register and written out to the SSTATn register location of the LLI before the start of the next block.

21.15.9 reg_DSTATAR_type (DSTATAR0)—Offset 38h

After the completion of each block transfer, hardware can retrieve the destination status information from the address pointed to by the contents of the DSTATARx register.

Access Method

DSTATAR0: [BAR + 98000h] + 38h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	DSTATAR: Pointer from where hardware can fetch the destination status information, which is registered in the DSTATn register and written out to the DSTATn register location of the LLI before the start of the next block.

21.15.10 reg_CFG_LO_type (CFG_LO0)—Offset 40h

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer. This Register should be programmed to enabling the channel

Access Method

CFG_LO0: [BAR + 98000h] + 40h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000203h

Intel Atom® Processor E3800 Product Family
Datasheet
2947

Bit Range	Default & Access	Description
8	0h RW	CH_SUSP: Channel Suspend. Suspends all DMA data transfers from the source until this bit is cleared. There is no guarantee that the current transaction will complete. Can also be used in conjunction with CFGx.FIFO_EMPTY to cleanly disable a channel without losing any data. 0 = Not suspended. 1 = Suspend DMA transfer from the source.
7	0h RW	SS_UPD_EN: Source Status Update Enable. Source status information is fetched only from the location pointed to by the SSTATARn register, stored in the SSTATn register and written out to the SSTATn location of the LLI if SS_UPD_EN is high. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
6	0h RW	DS_UPD_EN: Destination Status Update Enable. Destination status information is fetched only from the location pointed to by the DSTATARn register, stored in the DSTATn register and written out to the DSTATn location of the LLI if DS_UPD_EN is high. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
5	0h RW	CTL_HI_UPD_EN: CTL_HI Update Enable. If set, the CTL_HI register is written out to the CTL_HI location of the LLI. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
4	0h RO	RSVD_4_4: Reserved
3	0h RW	HSHAKE_NP_WR: 0x1 : Issues Non-Posted writes on HW-Handshake on DMA Write Port 0x0 : Issues Posted writes on HW-Handshake on DMA Write Port (Except end-of-block writes which will be Non-Posted)
2	0h RW	ALL_NP_WR: 0x1 : Forces ALL writes to be Non-Posted on DMA Write Port 0x0 : Non-Posted Writes will only be used at end of block transfers and in HW-Handshake (if HW_NP_WR=1); for all other cases, Posted Writes will be used.
1	1h RW	SRC_BURST_ALIGN: 0x1 : SRC Burst Transfers are broken at a Burst Length aligned boundary 0x0 : SRC Burst Transfers are not broken at a Burst Length aligned boundary
0	1h RW	DST_BURST_ALIGN: 0x1 : DST Burst Transfers are broken at a Burst Length aligned boundary 0x0 : DST Burst Transfers are not broken at a Burst Length aligned boundary

21.15.11 reg_CFG_HI_type (CFG_HI0)—Offset 44h

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer. This Register should be programmed to enabling the channel

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CFG_HI0: [BAR + 98000h] + 44h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31				28				24				20				16				12				8				4				0			
0 0 0 0				0 0 0 0				0 0 0 0				0 0 0 0				0 0 0 0				0 0 0 0				0 0 0 0				0 0 0 0							
DST_PER_EXT				SRC_PER_EXT				WR_ISSUE_THD								RD_ISSUE_THD								DST_PER				SRC_PER							

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2 \wedge \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2 \wedge \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.15.12 reg_SGR_type (SGR0)—Offset 48h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SGR0: [BAR + 98000h] + 48h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZ: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZ: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.15.18 reg_CTL_HI_type (CTL_HI1)—Offset 74h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI1: [BAR + 98000h] + 74h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.15.19 reg_SSTAT_type (SSTAT1)—Offset 78h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTAT1: [BAR + 98000h] + 78h

BAR Type: PCI Configuration Register (Size: 32 bits)

SAR								

Bit Range	Default & Access	Description
31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.28 reg_DAR_type (DAR2)—Offset B8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

Access Method

7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.15.31 reg_CTL_HI_type (CTL_HI2)—Offset CCh

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI2: [BAR + 98000h] + CCh

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.15.32 reg_SSTAT_type (SSTAT2)—Offset D0h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

DST_PER_EXT				SRC_PER_EXT				WR_ISSUE_THD								RD_ISSUE_THD								DST_PER				SRC_PER							

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2 \wedge \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2 \wedge \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.15.38 reg_SGR_type (SGR2)—Offset F8h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SGR2: [BAR + 98000h] + F8h

BAR Type: PCI Configuration Register (Size: 32 bits)

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.15.45 reg_SSTAT_type (SSTAT3)—Offset 128h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

SSTAT

Bit Range	Default & Access	Description
31:0	0h RW	SSTAT: Source status information retrieved by hardware from the address pointed to by the contents of the Source Status Address Register. This register is a temporary placeholder for the source status information on its way to the SSTATn register location of the LLI. The source status information should be retrieved by software from the SSTATn register location of the LLI, and not by a read of this register over the DMA slave interface.

21.15.46 reg_DSTAT_type (DSTAT3)—Offset 130h

After the completion of each block transfer, hardware can retrieve the destination status information from the address pointed to by the contents of the DSTATARx register. This status information is then stored in the DSTATx register and written out to the DSTATx register location of the LLI. Note : This register is a temporary placeholder for the destination status information on its way to the DSTATx register location of the LLI. The destination status information should be retrieved by software from the DSTATx register location of the LLI and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

DSTAT3: [BAR + 98000h] + 130h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

21.15.49 reg_CFG_LO_type (CFG_LO3)—Offset 148h

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer. This Register should be programmed to enabling the channel

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CFG_LO3: [BAR + 98000h] + 148h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000203h

October 2018
Document Number: 538136, Rev. 4.3

Bit Range	Default & Access	Description
8	0h RW	CH_SUSP: Channel Suspend. Suspends all DMA data transfers from the source until this bit is cleared. There is no guarantee that the current transaction will complete. Can also be used in conjunction with CFGx.FIFO_EMPTY to cleanly disable a channel without losing any data. 0 = Not suspended. 1 = Suspend DMA transfer from the source.
7	0h RW	SS_UPD_EN: Source Status Update Enable. Source status information is fetched only from the location pointed to by the SSTATARn register, stored in the SSTATn register and written out to the SSTATn location of the LLI if SS_UPD_EN is high. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
6	0h RW	DS_UPD_EN: Destination Status Update Enable. Destination status information is fetched only from the location pointed to by the DSTATARn register, stored in the DSTATn register and written out to the DSTATn location of the LLI if DS_UPD_EN is high. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
5	0h RW	CTL_HI_UPD_EN: CTL_HI Update Enable. If set, the CTL_HI register is written out to the CTL_HI location of the LLI. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
4	0h RO	RSVD_4_4: Reserved
3	0h RW	HSHAKE_NP_WR: 0x1 : Issues Non-Posted writes on HW-Handshake on DMA Write Port 0x0 : Issues Posted writes on HW-Handshake on DMA Write Port (Except end-of-block writes which will be Non-Posted)
2	0h RW	ALL_NP_WR: 0x1 : Forces ALL writes to be Non-Posted on DMA Write Port 0x0 : Non-Posted Writes will only be used at end of block transfers and in HW-Handshake (if HW_NP_WR=1); for all other cases, Posted Writes will be used.
1	1h RW	SRC_BURST_ALIGN: 0x1 : SRC Burst Transfers are broken at a Burst Length aligned boundary 0x0 : SRC Burst Transfers are not broken at a Burst Length aligned boundary
0	1h RW	DST_BURST_ALIGN: 0x1 : DST Burst Transfers are broken at a Burst Length aligned boundary 0x0 : DST Burst Transfers are not broken at a Burst Length aligned boundary

21.15.50 reg_CFG_HI_type (CFG_HI3)—Offset 14Ch

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer. This Register should be programmed to enabling the channel

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CFG_HI3: [BAR + 98000h] + 14Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31		28		24		20		16		12		8		4		0			
0		0		0		0		0		0		0		0		0			
DST_PER_EXT		SRC_PER_EXT		WR_ISSUE_THD						RD_ISSUE_THD						DST_PER		SRC_PER	

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2^{\wedge} \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2^{\wedge} \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.15.51 reg_SGR_type (SGR3)—Offset 150h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SGR3: [BAR + 98000h] + 150h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Bit Range	Default & Access	Description
31:20	0h RW	DSC : Destination scatter count. Destination contiguous transfer count between successive scatter boundaries.
19:0	0h RW	DSI : Destination scatter interval.

21.15.53 reg_SAR_type (SAR4)—Offset 160h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAR4: [BAR + 98000h] + 160h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

21.15.56 reg_CTL_LO_type (CTL_LO4)—Offset 178h

This register contains fields that control the DMA transfer. The CTL_LO register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_LO4: [BAR + 98000h] + 178h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31				28				24				20				16				12				8				4				0																																			
0				0				0				0				0				0				0				0				0

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZE: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZE: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.15.57 reg_CTL_HI_type (CTL_HI4)—Offset 17Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI4: [BAR + 98000h] + 17Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.15.58 reg_SSTAT_type (SSTAT4)—Offset 180h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTAT4: [BAR + 98000h] + 180h

In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2 \wedge \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2 \wedge \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.15.64 reg_SGR_type (SGR4)—Offset 1A8h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SGR4: [BAR + 98000h] + 1A8h

				LLP_DST_EN												DST_SCATTER_EN												SRC_GATHER_EN															

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZ: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZ: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.15.70 reg_CTL_HI_type (CTL_HI5)—Offset 1D4h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI5: [BAR + 98000h] + 1D4h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI.CTL_HI.DONE bit to see when a block transfer is complete. The LLI.CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.15.71 reg_SSTAT_type (SSTAT5)—Offset 1D8h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTAT5: [BAR + 98000h] + 1D8h

BAR Type: PCI Configuration Register (Size: 32 bits)

DSC				DSI				

Bit Range	Default & Access	Description
31:20	0h RW	DSC : Destination scatter count. Destination contiguous transfer count between successive scatter boundaries.
19:0	0h RW	DSI : Destination scatter interval.

21.15.79 reg_SAR_type (SAR6)—Offset 210h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAR6: [BAR + 98000h] + 210h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Access Method

DAR6: [BAR + 98000h] + 218h

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Diagram illustrating the structure of the 32-bit DAR field. The field is divided into eight 4-bit segments, each containing four '0' bits. The segments are labeled with bit positions 31, 28, 24, 20, 16, 12, 8, and 4 from left to right. The label 'DAR' is positioned below the first four segments.

21.15.82 reg_CTL_LO_type (CTL_LO6)—Offset 228h

This register contains fields that control the DMA transfer. The CTL_LO register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_LO6: [BAR + 98000h] + 228h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31				28				24				20				16				12				8				4				0																																			
0				0				0				0				0				0				0				0				0

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZ: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZ: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.15.83 reg_CTL_HI_type (CTL_HI6)—Offset 22Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI6: [BAR + 98000h] + 22Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.15.84 reg_SSTAT_type (SSTAT6)—Offset 230h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTAT6: [BAR + 98000h] + 230h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Intel Atom® Processor E3800 Product Family
Datasheet
3013

Bit Range	Default & Access	Description
8	0h RW	CH_SUSP: Channel Suspend. Suspends all DMA data transfers from the source until this bit is cleared. There is no guarantee that the current transaction will complete. Can also be used in conjunction with CFGx.FIFO_EMPTY to cleanly disable a channel without losing any data. 0 = Not suspended. 1 = Suspend DMA transfer from the source.
7	0h RW	SS_UPD_EN: Source Status Update Enable. Source status information is fetched only from the location pointed to by the SSTATARn register, stored in the SSTATn register and written out to the SSTATn location of the LLI if SS_UPD_EN is high. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
6	0h RW	DS_UPD_EN: Destination Status Update Enable. Destination status information is fetched only from the location pointed to by the DSTATARn register, stored in the DSTATn register and written out to the DSTATn location of the LLI if DS_UPD_EN is high. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
5	0h RW	CTL_HI_UPD_EN: CTL_HI Update Enable. If set, the CTL_HI register is written out to the CTL_HI location of the LLI. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
4	0h RO	RSVD_4_4: Reserved
3	0h RW	HSHAKE_NP_WR: 0x1 : Issues Non-Posted writes on HW-Handshake on DMA Write Port 0x0 : Issues Posted writes on HW-Handshake on DMA Write Port (Except end-of-block writes which will be Non-Posted)
2	0h RW	ALL_NP_WR: 0x1 : Forces ALL writes to be Non-Posted on DMA Write Port 0x0 : Non-Posted Writes will only be used at end of block transfers and in HW-Handshake (if HW_NP_WR=1); for all other cases, Posted Writes will be used.
1	1h RW	SRC_BURST_ALIGN: 0x1 : SRC Burst Transfers are broken at a Burst Length aligned boundary 0x0 : SRC Burst Transfers are not broken at a Burst Length aligned boundary
0	1h RW	DST_BURST_ALIGN: 0x1 : DST Burst Transfers are broken at a Burst Length aligned boundary 0x0 : DST Burst Transfers are not broken at a Burst Length aligned boundary

21.15.89 reg_CFG_HI_type (CFG_HI6)—Offset 254h

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer. This Register should be programmed to enabling the channel

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CFG_HI6: [BAR + 98000h] + 254h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31				28				24				20				16				12				8				4				0															
0				0				0				0				0				0				0				0				0															
DST_PER_EXT				SRC_PER_EXT				WR_ISSUE_THD																RD_ISSUE_THD																DST_PER				SRC_PER			

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2 \wedge \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2 \wedge \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.15.90 reg_SGR_type (SGR6)—Offset 258h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SGR6: [BAR + 98000h] + 258h

BAR Type: PCI Configuration Register (Size: 32 bits)

19:0	0h RW	DSI: Destination scatter interval.

21.15.92 reg_SAR_type (SAR7)—Offset 268h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAR7: [BAR + 98000h] + 268h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Intel Atom® Processor E3800 Product Family
Datasheet
3017

Bit Range	Default & Access	Description
31:0	0h RW	DAR: Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.94 reg_LLp_type (LLP7)—Offset 278h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

LOC								RSVD2

Bit Range	Default & Access	Description
31:2	00000000h RW	LOC: Starting Address In Memory of next LLI if block chaining is enabled. Note that the two LSBs of the starting address are not stored because the address is assumed to be aligned to a 32-bit boundary. LLI accesses are always 32-bit accesses and cannot be changed or programmed to anything other than 32-bit.
1:0	0h RO	RSVD2: Reserved

21.15.95 reg_CTL_LO_type (CTL_LO7)—Offset 280h

This register contains fields that control the DMA transfer. The CTL_LO register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_LO7: [BAR + 98000h] + 280h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RSVD	LLP_SRC_EN	LLP_DST_EN	RSVD1	TT_FC	RSVD2	DST_SCATTER_EN	SRC_GATHER_EN	SRC_MSIZ
						DEST_MSIZ	SINC	RSVD3
						DINC	RSVD4	SRC_TR_WIDTH
								DST_TR_WIDTH
								INT_EN

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZ: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZ: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.15.96 reg_CTL_HI_type (CTL_HI7)—Offset 284h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI7: [BAR + 98000h] + 284h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.15.97 reg_SSTAT_type (SSTAT7)—Offset 288h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTAT7: [BAR + 98000h] + 288h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

0			0				0				0				0				0				0				0				0			
DST_PER_EXT			SRC_PER_EXT				WR_ISSUE_THD								RD_ISSUE_THD								DST_PER				SRC_PER							

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2 \wedge \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2 \wedge \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.15.103 reg_SGR_type (SGR7)—Offset 2B0h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

31:8	0h RO	RSVD: Reserved
7:0	0h RO	STATUS: Interrupt status

21.15.115 reg_Mask_type (MaskTfr)—Offset 310h

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel, for example, MaskTfr(2) is the mask bit for the Channel 2 transfer complete interrupt. When the source peripheral of DMA channel i is memory, then the source transaction complete interrupt, MaskSrcTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined signal. Similarly, when the destination peripheral of DMA channel i is memory, then the destination transaction complete interrupt, MaskDstTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined(_n) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged.

Writing a 1 to any bit in these registers unmasks the corresponding interrupt, thus allowing the DMA to set the appropriate bit in the Status registers and int_* port signals.

0	0h RW	DMA_EN: DMA Enable bit. 0 = DMA Disabled 1 = DMA Enabled

21.15.127 reg_ChEnReg_type (ChEnReg)—Offset 3A0h

This is the DMA Channel Enable Register. If software needs to set up a new channel, then it can read this register in order to find out which channels are currently inactive, it can then enable an inactive channel with the required priority. All bits of this register are cleared to 0 when the global DMA channel enable bit, `DmaCrgReg(0)`, is 0. When the global channel enable bit is 0, then a write to the `ChEnReg` register is ignored and a read will always read back 0. The channel enable bit, `ChEnReg.CH_EN`, is written only if the corresponding channel write enable bit, `ChEnReg.CH_EN_WE`, is asserted on the

same OCP write transfer. For example, writing hex 01x1 writes a 1 into ChEnReg(0), while ChEnReg(7:1) remains unchanged. Writing hex 00xx leaves ChEnReg(7:0) unchanged. Note that a read-modified write is not required.

Access Method

0	0	0	0	0	0	0	0	0
RSVD2				WT_CLASS_1				WT_CLASS_0

Bit Range	Default & Access	Description
31:22	0h RO	RSVD2: Reserved

Type: Memory Mapped I/O Register
(Size: 32 bits)

BAR Type: PCI Configuration Register (Size: 32 bits)

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RSVD1				WT_CLASS_7				WT_CLASS_6

Bit Range	Default & Access	Description
31:22	0h RO	RSVD1: Reserved
21:11	0h RW	WT_CLASS_7: Class Weight 7: Value of K assigns a weight of (K+1) to Class 7. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Class Weight ranges from 1 to 2048 bytes.
10:0	0h RW	WT_CLASS_6: Class Weight 6: Value of K assigns a weight of (K+1) to Class 6. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Class Weight ranges from 1 to 2048 bytes.

21.15.132 reg_FIFO_PARTITION0_LO_type (FifoPartition0_LO)—Offset 400h

Intel Atom® Processor E3800 Product Family
Datasheet
3044

Type: Memory Mapped I/O Register
(Size: 32 bits)

FifoPartition0_LO: [BAR + 98000h] + 400h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
RSVD2	PARTITION_UPDATE		PSIZE_CH_1			PSIZE_CH_0		

Bit Range	Default & Access	Description
31:27	0h RO	RSVD2: Reserved
26	0h RW	PARTITION_UPDATE: SW needs to write to this bit for the partitioning assignments to take effect.
25:13	0h RW	PSIZE_CH_1: Partition Byte Size assigned to Channel 1. Ranges from 0 Bytes to (2 ¹³ - 1)=8191 Bytes. However, size needs to be DW Aligned, i.e. a multiple of 4.
12:0	0h RW	PSIZE_CH_0: Partition Byte Size assigned to Channel 0. Ranges from 0 Bytes to (2 ¹³ - 1)=8191 Bytes. However, size needs to be DW Aligned, i.e. a multiple of 4.

21.15.133 reg_FIFO_PARTITION0_HI_type (FifoPartition0_HI)—Offset 404h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

FifoPartition0_HI: [BAR + 98000h] + 404h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
RSVD1		PSIZE_CH_3				PSIZE_CH_2		

Bit Range	Default & Access	Description
31:26	0h RO	RSVD1: Reserved
25:13	0h RW	PSIZE_CH_3: Partition Byte Size assigned to Channel 3. Ranges from 0 Bytes to (2 ¹³ - 1)=8191 Bytes. However, size needs to be DW Aligned, i.e. a multiple of 4.

Bit Range	Default & Access	Description
31:26	0h RO	RSVD1: Reserved
25:13	0h RW	PSIZE_CH_7: Partition Byte Size assigned to Channel 7. Ranges from 0 Bytes to (2^13 - 1)=8191 Bytes. However, size needs to be DW Aligned, i.e. a multiple of 4.
12:0	0h RW	PSIZE_CH_6: Partition Byte Size assigned to Channel 6. Ranges from 0 Bytes to (2^13 - 1)=8191 Bytes. However, size needs to be DW Aligned, i.e. a multiple of 4.

21.15.136 reg_SAI_Error_type (SAI_ERR)—Offset 410h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAI ERR: [BAR + 98000h] + 410h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RSVD							CH_SAI_ERR	

Bit Range	Default & Access	Description
31:8	0h RO	RSVD: Reserved
7:0	0h RO	CH_SAI_ERR: 1: SAI Error occurred on Ch [n] 0: No SAI Error occurred on Ch [n] SAI_ERROR[n] is set by HW on SAI violation for channel [n]. All bits get cleared by SW when reading this register

21.15.137 reg_GLOBAL_CFG_type (GLOBAL_CFG)—Offset 418h

GLOBAL_CFG: GLOBAL DMA Configuration Register

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

GLOBAL CFG: [BAR + 98000h] + 418h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0	
0	0	0	0	0	0	0	0	0	0
SCRATCH_PAD FRR_T11_REG									

Bit Range	Default & Access	Description
31:1	0h RW	SCRATCH_PAD: This field will have all bits with R/W attribute to be used for future configuration and de-feature bits.
0	0b RW	ERR_ILL_REG: 0x1 : Issue ERR response on reading illegal (non-existing) registers 0x0 : Issue DVA response on reading illegal (non-existing) registers

21.16 Low Power Audio DMA1 Memory Mapped IO Registers

21.16.1 reg_SAR_type (SAR0)—Offset 0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAR0: [BAR + 9C000h] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

21.16.2 reg_DAR_type (DAR0)—Offset 8h

Access Method

DARO: [BAR + 9C000h] + 8h

BAR Reference: [B:0, D:21, F:0] + 10h

	31	28	24	20	16	12	8	4	0
	0	0	0	0	0	0	0	0	0
DAR	0	0	0	0	0	0	0	0	0

Bit Range	Default & Access	Description
31:0	0h RW	DAR: Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length > 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.3 reg_LLPType (LLP0)—Offset 10h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled. The LLP register has two functions: The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer—single or multi-block. Table shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists. The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Access Method

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZ: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZ: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.16.5 reg_CTL_HI_type (CTL_HI0)—Offset 1Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI0: [BAR + 9C000h] + 1Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.16.6 reg_SSTAT_type (SSTAT0)—Offset 20h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTAT0: [BAR + 9C000h] + 20h

BAR Type: PCI Configuration Register (Size: 32 bits)

0			0				0				0				0				0				0				0				0			
DST_PER_EXT			SRC_PER_EXT				WR_ISSUE_THD								RD_ISSUE_THD								DST_PER				SRC_PER							

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2 \wedge \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2 \wedge \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.16.12 reg_SGR_type (SGR0)—Offset 48h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAR								

Bit Range	Default & Access	Description
31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.15 reg_DAR_type (DAR1)—Offset 60h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

Access Method

				LLP_DST_EN																																																											

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZE: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZE: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.16.18 reg_CTL_HI_type (CTL_HI1)—Offset 74h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI1: [BAR + 9C000h] + 74h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.16.19 reg_SSTAT_type (SSTAT1)—Offset 78h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTAT1: [BAR + 9C000h] + 78h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

0	0	0	0	0	0	0	0	0

Bit Range	Default & Access	Description
31:0	0h RW	DSTAT: Destination status information retrieved by hardware from the address pointed to by the contents of the Destination Status Address Register. This register is a temporary placeholder for the destination status information on its way to the DSTATn register location of the LLI. The destination status information should be retrieved by software from the DSTATn register location of the LLI and not by a read of this register over the DMA slave interface.

21.16.21 reg_SSTATAR_type (SSTATAR1)—Offset 88h

After the completion of each block transfer, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTATAR1: [BAR + 9C000h] + 88h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	SSTATAR: Pointer from where hardware can fetch the source status information, which is registered in the SSTATn register and written out to the SSTATn register location of the LLI before the start of the next block.

21.16.22 reg_DSTATAR_type (DSTATAR1)—Offset 90h

After the completion of each block transfer, hardware can retrieve the destination status information from the address pointed to by the contents of the DSTATARx register.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

DSTATAR1: [BAR + 9C000h] + 90h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	DSTATAR: Pointer from where hardware can fetch the destination status information, which is registered in the DSTATn register and written out to the DSTATn register location of the LLI before the start of the next block.

21.16.23 reg_CFG_LO_type (CFG_LO1)—Offset 98h

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer. This Register should be programmed to enabling the channel

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CFG_LO1: [BAR + 9C000h] + 98h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000203h

Intel Atom® Processor E3800 Product Family
Datasheet
3071

Bit Range	Default & Access	Description
8	0h RW	CH_SUSP: Channel Suspend. Suspends all DMA data transfers from the source until this bit is cleared. There is no guarantee that the current transaction will complete. Can also be used in conjunction with CFGx.FIFO_EMPTY to cleanly disable a channel without losing any data. 0 = Not suspended. 1 = Suspend DMA transfer from the source.
7	0h RW	SS_UPD_EN: Source Status Update Enable. Source status information is fetched only from the location pointed to by the SSTATARn register, stored in the SSTATn register and written out to the SSTATn location of the LLI if SS_UPD_EN is high. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
6	0h RW	DS_UPD_EN: Destination Status Update Enable. Destination status information is fetched only from the location pointed to by the DSTATARn register, stored in the DSTATn register and written out to the DSTATn location of the LLI if DS_UPD_EN is high. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
5	0h RW	CTL_HI_UPD_EN: CTL_HI Update Enable. If set, the CTL_HI register is written out to the CTL_HI location of the LLI. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
4	0h RO	RSVD_4_4: Reserved
3	0h RW	HSHAKE_NP_WR: 0x1 : Issues Non-Posted writes on HW-Handshake on DMA Write Port 0x0 : Issues Posted writes on HW-Handshake on DMA Write Port (Except end-of-block writes which will be Non-Posted)
2	0h RW	ALL_NP_WR: 0x1 : Forces ALL writes to be Non-Posted on DMA Write Port 0x0 : Non-Posted Writes will only be used at end of block transfers and in HW-Handshake (if HW_NP_WR=1); for all other cases, Posted Writes will be used.
1	1h RW	SRC_BURST_ALIGN: 0x1 : SRC Burst Transfers are broken at a Burst Length aligned boundary 0x0 : SRC Burst Transfers are not broken at a Burst Length aligned boundary
0	1h RW	DST_BURST_ALIGN: 0x1 : DST Burst Transfers are broken at a Burst Length aligned boundary 0x0 : DST Burst Transfers are not broken at a Burst Length aligned boundary

21.16.24 reg_CFG_HI_type (CFG_HI1)—Offset 9Ch

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer. This Register should be programmed to enabling the channel

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CFG_HI1: [BAR + 9C000h] + 9Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31				28				24				20				16				12				8				4				0															
0				0				0				0				0				0				0				0				0															
DST_PER_EXT				SRC_PER_EXT				WR_ISSUE_THD																RD_ISSUE_THD																DST_PER				SRC_PER			

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2 \wedge \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2 \wedge \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.16.25 reg_SGR_type (SGR1)—Offset A0h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SGR1: [BAR + 9C000h] + A0h

BAR Type: PCI Configuration Register (Size: 32 bits)

31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.16.32 reg_SSTAT_type (SSTAT2)—Offset D0h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

DST_PER_EXT				SRC_PER_EXT				WR_ISSUE_THD								RD_ISSUE_THD								DST_PER				SRC_PER							

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2 \wedge \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2 \wedge \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.16.38 reg_SGR_type (SGR2)—Offset F8h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZ: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZ: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.16.44 reg_CTL_HI_type (CTL_HI3)—Offset 124h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI3: [BAR + 9C000h] + 124h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.16.45 reg_SSTAT_type (SSTAT3)—Offset 128h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

3	0h RW	HSHAKE_NP_WR: 0x1 : Issues Non-Posted writes on HW-Handshake on DMA Write Port 0x0 : Issues Posted writes on HW-Handshake on DMA Write Port (Except end-of-block writes which will be Non-Posted)
2	0h RW	ALL_NP_WR: 0x1 : Forces ALL writes to be Non-Posted on DMA Write Port 0x0 : Non-Posted Writes will only be used at end of block transfers and in HW-Handshake (if HW_NP_WR=1); for all other cases, Posted Writes will be used.
1	1h RW	SRC_BURST_ALIGN: 0x1 : SRC Burst Transfers are broken at a Burst Length aligned boundary 0x0 : SRC Burst Transfers are not broken at a Burst Length aligned boundary
0	1h RW	DST_BURST_ALIGN: 0x1 : DST Burst Transfers are broken at a Burst Length aligned boundary 0x0 : DST Burst Transfers are not broken at a Burst Length aligned boundary

21.16.50 reg_CFG_HI_type (CFG_HI3)—Offset 14Ch

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer. This Register should be programmed to enabling the channel

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CFG_HI3: [BAR + 9C000h] + 14Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31				28				24				20				16				12				8				4				0															
0				0				0				0				0				0				0				0				0															
DST_PER_EXT				SRC_PER_EXT				WR_ISSUE_THD																RD_ISSUE_THD																DST_PER				SRC_PER			

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2 \wedge \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2 \wedge \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.16.51 reg_SGR_type (SGR3)—Offset 150h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SGR3: [BAR + 9C000h] + 150h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

19:0	0h RW	DSI: Destination scatter interval.

21.16.53 reg_SAR_type (SAR4)—Offset 160h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAR4: [BAR + 9C000h] + 160h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

[illegible]

Bit Range	Default & Access	Description
31:0	0h RW	DAR: Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length = 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.55 reg_LLQ_type (LLP4)—Offset 170h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled. The LLP register has two functions: The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer—single or multi-block. Table shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists. The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZ: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZ: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.16.57 reg_CTL_HI_type (CTL_HI4)—Offset 17Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI4: [BAR + 9C000h] + 17Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.16.58 reg_SSTAT_type (SSTAT4)—Offset 180h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Default: 00000000h

[illegible]

21.16.62 reg_CFG_LO_type (CFG_LO4)—Offset 1A0h

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer. This Register should be programmed to enabling the channel

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CFG_LO4: [BAR + 9C000h] + 1A0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000203h

October 2018
Document Number: 538136, Rev. 4.3

Bit Range	Default & Access	Description
8	0h RW	CH_SUSP: Channel Suspend. Suspends all DMA data transfers from the source until this bit is cleared. There is no guarantee that the current transaction will complete. Can also be used in conjunction with CFGx.FIFO_EMPTY to cleanly disable a channel without losing any data. 0 = Not suspended. 1 = Suspend DMA transfer from the source.
7	0h RW	SS_UPD_EN: Source Status Update Enable. Source status information is fetched only from the location pointed to by the SSTATARn register, stored in the SSTATn register and written out to the SSTATn location of the LLI if SS_UPD_EN is high. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
6	0h RW	DS_UPD_EN: Destination Status Update Enable. Destination status information is fetched only from the location pointed to by the DSTATARn register, stored in the DSTATn register and written out to the DSTATn location of the LLI if DS_UPD_EN is high. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
5	0h RW	CTL_HI_UPD_EN: CTL_HI Update Enable. If set, the CTL_HI register is written out to the CTL_HI location of the LLI. This bit is ignored if (LLP_EN == 0) or (LLP_WB_EN == 0)
4	0h RO	RSVD_4_4: Reserved
3	0h RW	HSHAKE_NP_WR: 0x1 : Issues Non-Posted writes on HW-Handshake on DMA Write Port 0x0 : Issues Posted writes on HW-Handshake on DMA Write Port (Except end-of-block writes which will be Non-Posted)
2	0h RW	ALL_NP_WR: 0x1 : Forces ALL writes to be Non-Posted on DMA Write Port 0x0 : Non-Posted Writes will only be used at end of block transfers and in HW-Handshake (if HW_NP_WR=1); for all other cases, Posted Writes will be used.
1	1h RW	SRC_BURST_ALIGN: 0x1 : SRC Burst Transfers are broken at a Burst Length aligned boundary 0x0 : SRC Burst Transfers are not broken at a Burst Length aligned boundary
0	1h RW	DST_BURST_ALIGN: 0x1 : DST Burst Transfers are broken at a Burst Length aligned boundary 0x0 : DST Burst Transfers are not broken at a Burst Length aligned boundary

21.16.63 reg_CFG_HI_type (CFG_HI4)—Offset 1A4h

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer. This Register should be programmed to enabling the channel

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CFG_HI4: [BAR + 9C000h] + 1A4h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

0 0 0 0 0		0 0 0 0 0				0 0 0 0 0				0 0 0 0 0				0 0 0 0 0				0 0 0 0 0				0 0 0 0 0				0 0 0 0 0							
DST_PER_EXT		SRC_PER_EXT		WR_ISSUE_THD										RD_ISSUE_THD										DST_PER				SRC_PER					

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2^{\wedge} \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2^{\wedge} \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.16.64 reg_SGR_type (SGR4)—Offset 1A8h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SGR4: [BAR + 9C000h] + 1A8h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

SGC				SGI				

Bit Range	Default & Access	Description
31:20	0h RW	SGC: Source gather count. Source contiguous transfer count between successive gather boundaries.
19:0	0h RW	SGI: Source gather interval.

21.16.65 reg_DSR_type (DSR4)—Offset 1B0h

The Destination Scatter register contains two fields: Destination scatter count field (DSRx.DSC) . Specifies the number of contiguous destination transfers of CTLx.DST_TR_WIDTH between successive scatter boundaries. Destination scatter interval field (DSRx.DSI) . Specifies the destination address increment/decrement in multiples of CTLx.DST_TR_WIDTH on a scatter boundary when scatter mode is enabled for the destination transfer. The CTLx.DINC field controls whether the address increments or decrements. When the CTLx.DINC field indicates a fixed address control, then the address remains constant throughout the transfer and the DSRx register is ignored.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

DSR4: [BAR + 9C000h] + 1B0h

BAR Type: PCI Configuration Register (Size: 32 bits)

Bit Range	Default & Access	Description
31:20	0h RW	DSC: Destination scatter count. Destination contiguous transfer count between successive scatter boundaries.
19:0	0h RW	DSI: Destination scatter interval.

21.16.66 reg_SAR_type (SAR5)—Offset 1B8h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAR5: [BAR + 9C000h] + 1B8h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

21.16.69 reg_CTL_LO_type (CTL_LO5)—Offset 1D0h

This register contains fields that control the DMA transfer. The CTL_LO register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_LO5: [BAR + 9C000h] + 1D0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31				28				24				20				16				12				8				4				0																																			
0				0				0				0				0				0				0				0				0

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZE: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZE: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.16.70 reg_CTL_HI_type (CTL_HI5)—Offset 1D4h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI5: [BAR + 9C000h] + 1D4h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.16.71 reg_SSTAT_type (SSTAT5)—Offset 1D8h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTAT5: [BAR + 9C000h] + 1D8h

BAR Type: PCI Configuration Register (Size: 32 bits)

21.16.78 reg_DSR_type (DSR5)—Offset 208h

The Destination Scatter register contains two fields: Destination scatter count field (DSRx.DSC) . Specifies the number of contiguous destination transfers of CTLx.DST_TR_WIDTH between successive scatter boundaries. Destination scatter interval field (DSRx.DSI) . Specifies the destination address increment/decrement in multiples of CTLx.DST_TR_WIDTH on a scatter boundary when scatter mode is enabled for the destination transfer. The CTLx.DINC field controls whether the address increments or decrements. When the CTLx.DINC field indicates a fixed address control, then the address remains constant throughout the transfer and the DSRx register is ignored.

Access Method

19:0	0h RW	DSI: Destination scatter interval.

21.16.79 reg_SAR_type (SAR6)—Offset 210h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAR6: [BAR + 9C000h] + 210h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Intel Atom® Processor E3800 Product Family
Datasheet
3119

Bit Range	Default & Access	Description
31:0	0h RW	DAR: Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length > 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.81 reg_LLp_type (LLP6)—Offset 220h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled. The LLP register has two functions: The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Access Method

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZ: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZ: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.16.83 reg_CTL_HI_type (CTL_HI6)—Offset 22Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI6: [BAR + 9C000h] + 22Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.16.84 reg_SSTAT_type (SSTAT6)—Offset 230h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

0			0				0				0				0				0				0				0				0			
DST_PER_EXT			SRC_PER_EXT				WR_ISSUE_THD								RD_ISSUE_THD								DST_PER				SRC_PER							

Bit Range	Default & Access	Description
31:30	0h RW	DST_PER_EXT: Destination Peripheral Extension : This 2-bit field is used to extend the DST_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall destination peripheral ID becomes DST_PER_EXT[1:0], DST_PER[3:0] which covers the (0-63) range.
29:28	0h RW	SRC_PER_EXT: Source Peripheral Extension : This 2-bit field is used to extend the SRC_PER field below beyond the Synopsys limit of (0-15) to accommodate additional hardware handshaking interfaces (16-63). In other words, the overall source peripheral ID becomes SRC_PER_EXT[1:0], SRC_PER[3:0] which covers the (0-63) range.
27:18	0h RW	WR_ISSUE_THD: Write Issue Threshold. Used to relax the issue criterion for Writes (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Write burst size = $(2^{\wedge} \text{DST_MSIZE}) * \text{TW}$.
17:8	0h RW	RD_ISSUE_THD: Read Issue Threshold. Used to relax the issue criterion for Reads (Refer to Section 4.1.1.4). Value ranges from 0 to $(2^{10}-1 = 1023)$ but should not exceed maximum Read burst size = $(2^{\wedge} \text{SRC_MSIZE}) * \text{TW}$.
7:4	0h RW	DST_PER: Destination Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the destination of channel n. The channel can then communicate with the destination peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS
3:0	0h RW	SRC_PER: Source Peripheral ID : Assigns a hardware handshaking interface (0 - 15) to the source of channel n. The channel can then communicate with the source peripheral connected to that interface through the assigned hardware handshaking interface. NOTE: For correct DMA operation, only one peripheral (source or destination) should be assigned to the same handshaking interface. For more details on mapping please refer to 3.5.3 HARDWARE HANDSHAKE INTERFACE MAPPING TO DMA CHANNELS

21.16.90 reg_SGR_type (SGR6)—Offset 258h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

Access Method

Bit Range	Default & Access	Description
31:29	0h RO	RSVD: Reserved
28	0h RW	LLP_SRC_EN: Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	LLP_DST_EN: Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	RSVD1: RSVD
21:20	0h RW	TT_FC: Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	RSVD2: Reserved
18	0h RW	DST_SCATTER_EN: Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	SRC_GATHER_EN: Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	SRC_MSIZE: Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	DEST_MSIZE: Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	SINC: Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)

Bit Range	Default & Access	Description
9	0h RO	RSVD3: Reserved
8	0h RW	DINC: Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	RSVD4: Reserved
6:4	0h RW	SRC_TR_WIDTH: Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	DST_TR_WIDTH: Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	INT_EN: Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

21.16.96 reg_CTL_HI_type (CTL_HI7)—Offset 284h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled. If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

CTL_HI7: [BAR + 9C000h] + 284h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CH_CLASS	CH_WEIGHT				DONE	BLOCK_TS		

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to $(2^{11}-1)=2047$, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HI, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesn't mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to $(2^{17}-1) = (128\text{ KB} - 1)$.

21.16.97 reg_SSTAT_type (SSTAT7)—Offset 288h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SSTAT7: [BAR + 9C000h] + 288h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

RSVD						STATUS		

Bit Range	Default & Access	Description
31:8	0h RO	RSVD: Reserved
7:0	0h RO	STATUS: Interrupt status

21.16.115 reg_Mask_type (MaskTfr)—Offset 310h

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel, for example, MaskTfr(2) is the mask bit for the Channel 2 transfer complete interrupt. When the source peripheral of DMA channel *i* is memory, then the source transaction complete interrupt, MaskSrcTran(*i*), must be masked to prevent an erroneous triggering of an interrupt on the int_combined signal. Similarly, when the destination peripheral of DMA channel *i* is memory, then the destination transaction complete interrupt, MaskDstTran(*i*), must be masked to prevent an erroneous triggering of an interrupt on the int_combined(*n*) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged.

Writing a 1 to any bit in these registers unmask the corresponding interrupt, thus allowing the DMA to set the appropriate bit in the Status registers and int_* port signals.

21.16.129 reg_CLASS_PRIORITY0_HI_type (ClassPriority0_HI)—Offset 3BCh

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

ClassPriority0_HI: [BAR + 9C000h] + 3BCh

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0	
0	0	0	0	0	0	0	0	0	
RSVD1			STRICT_PRI	WT_CLASS_3			WT_CLASS_2		

Bit Range	Default & Access	Description
31:23	0h RO	RSVD1: Reserved
22	0h RW	STRICT_PRI: If set, Higher class values will always have higher priorities than lower class values. If not set, round-robin arbitration will be used between different classes using WT_CLASS_n values.
21:11	0h RW	WT_CLASS_3: Class Weight 3: Value of K assigns a weight of (K+1) to Class 3. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Class Weight ranges from 1 to 2048 bytes.
10:0	0h RW	WT_CLASS_2: Class Weight 2: Value of K assigns a weight of (K+1) to Class 2. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Class Weight ranges from 1 to 2048 bytes.

21.16.130 reg_CLASS_PRIORITY1_LO_type (ClassPriority1_LO)—Offset 3C0h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

ClassPriority1_LO: [BAR + 9C000h] + 3C0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Type: Memory Mapped I/O Register
(Size: 32 bits)

FifoPartition0_LO: [BAR + 9C000h] + 400h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0
RSVD2	PARTITION_UPDATE	PSIZE_CH_1	PSIZE_CH_0					

Bit Range	Default & Access	Description
31:27	0h RO	RSVD2: Reserved
26	0h RW	PARTITION_UPDATE: SW needs to write to this bit for the partitioning assignments to take effect.
25:13	0h RW	PSIZE_CH_1: Partition Byte Size assigned to Channel 1. Ranges from 0 Bytes to (2 ¹³ - 1)=8191 Bytes. However, size needs to be DW Aligned, i.e. a multiple of 4.
12:0	0h RW	PSIZE_CH_0: Partition Byte Size assigned to Channel 0. Ranges from 0 Bytes to (2 ¹³ - 1)=8191 Bytes. However, size needs to be DW Aligned, i.e. a multiple of 4.

21.16.133 reg_FIFO_PARTITION0_HI_type (FifoPartition0_HI)—Offset 404h

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

FifoPartition0_HI: [BAR + 9C000h] + 404h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0

RSVD1	PSIZE_CH_3	PSIZE_CH_2						

Bit Range	Default & Access	Description
31:26	0h RO	RSVD1: Reserved
25:13	0h RW	PSIZE_CH_3: Partition Byte Size assigned to Channel 3. Ranges from 0 Bytes to (2 ¹³ - 1)=8191 Bytes. However, size needs to be DW Aligned, i.e. a multiple of 4.

21.16.136 req SAI Error type (SAI_ERR)—Offset 410h

Bit Range	Default & Access	Description
31:26	0h RO	RSVD1: Reserved
25:13	0h RW	PSIZE_CH_7: Partition Byte Size assigned to Channel 7. Ranges from 0 Bytes to (2^13 - 1)=8191 Bytes. However, size needs to be DW Aligned, i.e. a multiple of 4.
12:0	0h RW	PSIZE_CH_6: Partition Byte Size assigned to Channel 6. Ranges from 0 Bytes to (2^13 - 1)=8191 Bytes. However, size needs to be DW Aligned, i.e. a multiple of 4.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAI_ERR: [BAR + 9C000h] + 410h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
RSVD							CH_SAI_ERR	

Bit Range	Default & Access	Description
31:8	0h RO	RSVD: Reserved
7:0	0h RO	CH_SAI_ERR: 1: SAI Error occurred on Ch [n] 0: No SAI Error occurred on Ch [n] SAI_ERROR[n] is set by HW on SAI violation for channel [n]. All bits get cleared by SW when reading this register

21.16.137 reg_GLOBAL_CFG_type (GLOBAL_CFG)—Offset 418h

GLOBAL_CFG: GLOBAL DMA Configuration Register

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

GLOBAL_CFG: [BAR + 9C000h] + 418h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
SCRATCH_PAD								ERR_ILL_REG

Bit Range	Default & Access	Description
31:1	0h RW	SCRATCH_PAD: This field will have all bits with R/W attribute to be used for future configuration and de-feature bits.
0	0b RW	ERR_ILL_REG: 0x1 : Issue ERR response on reading illegal (non-existing) registers 0x0 : Issue DVA response on reading illegal (non-existing) registers

22 Intel® Trusted Execution Engine (TXE)

This section describes the security components and capabilities of the Intel® Trusted Execution Engine (TXE) security co-processor.

Note: TXE firmware is required on the Bay Trail Platform as part of the PCU SPI flash image. PCU SPI must be setup in descriptor mode. For security reasons, primarily to lock PCU SPI flash access permission and OTP fuse programming, TXE Manufacturing Mode must be Disabled before shipping to customers. See your Intel® representative for details.

22.1 Features

22.1.1 Security Feature

The Intel® TXE is a security co-processor responsible for supporting and handling security. Features include:

- 32-bit RISC processor
- 256KB Data/Code RAM accessible only to the Intel® TXE
- 128KB On Chip Mask ROM for storage of Intel® TXE code
- Common Timer 1-100 μ S granularity, configurable interrupt (under FW control)
- Inter-Processor Communication for message passing between the Host CPU and Intel® TXE
- 64 byte input and output command buffers
- 256 byte shared payload (enables 2048-bit keys to be exchanged as part of the command)
- No Host CPU address domain access to the Intel® TXE address domain by any Host CPU address domain units
- Security controller has direct access to Host CPU address domain (Some Restrictions Apply). Multiple context DMA engine to transfer data between Host CPU address domain (System memory) and the Intel® TXE; programmable by the Intel® TXE CPU only.
- One multi-tiered FW Key Ladder and one Intel Key ladder.
- Paging DMA operations includes encryption/decryption and integrity check value (ICV) calculation. Auxiliary GPIOs to support input alert and two GP Outputs.

22.1.1.1 HW Accelerators

- DES/3DES (ECB, CBC) – 128b ABA key for 3DES Key Ladder Operations
- Three AES engines - Two fast -128 and one slow- 128/256

- Exponentiation Acceleration Unit (EAU) for modular exponentiation, modular reduction, large number addition, subtraction, and multiplication
- SHA1, SHA256/384/512, MD5

22.1.1.2 FW Utilities and Ciphers

- RSA (with EAU acceleration)
- Flash Write Enable/Disable
- Comprehensive IPC Command Set
- Chip Unique Key encryption key wrapping of other platform keys (Flash)

22.1.1.3 Downloadable FW Utilities and Ciphers

- Integrated Theft Deterrence Technology - Intel® Anti-Theft Technology (Intel® AT)
- Media Vault - content protection and distribution product specifically focused on online content for streaming and download
- One Time Programmable (OTP)

22.2 Register Map

See Chapters [Section 3, "Register Access Methods"](#) on page 69 and [Section 4, "Mapping Address Spaces"](#) on page 75 for additional information.

22.3 Intel® TXE PCI Configuration Registers

Table 239. Summary of TXE PCI Configuration Registers—0/26/0

Offset	Size (Bytes)	Register Name (Register Symbol)	Default Value
0–3h	4	"Device/Vendor ID (DEVVENDID)—Offset 0h" on page 3166	00108086h
4–7h	4	"Status Command (STATUSCOMMAND)—Offset 4h" on page 3166	00100000h
8–Bh	4	"Revision ID and Class Code (REVCLASSCODE)—Offset 8h" on page 3167	10800000h
C–Fh	4	"CLLATHEADERBISTR (CLLATHEADERBIST)—Offset Ch" on page 3168	00000000h
10–13h	4	"SAP Agent Memory BAR (SAPAGENTBAR)—Offset 10h" on page 3168	00000000h
14–17h	4	"Bridge Memory BAR (BRIDGEBAR)—Offset 14h" on page 3169	00000000h
18h + [0-3]*4h	4	"Dummy BAR[0-3] (DUMMY_BARS[0-3])—Offset 18h, Count 4, Stride 4h" on page 3170	00000000h
2C–2Fh	4	"SUBSYSTEMID—Offset 2Ch" on page 3170	00000000h
30–33h	4	"EXPANSION_ROM_BASEADDR—Offset 30h" on page 3171	00000000h
34–37h	4	"CAPABILITYPTR—Offset 34h" on page 3171	00000080h
3C–3Fh	4	"INTERRUPTREG—Offset 3Ch" on page 3172	00000100h
40–43h	4	"SEC_FW_STS1—Offset 40h" on page 3172	00000000h
44–47h	4	"SEC_MEM_REQ—Offset 44h" on page 3175	00000000h
48–4Bh	4	"SEC_FW_STS0—Offset 48h" on page 3175	00000000h
4Ch + [0-4]*4h	4	"PCI_CONF_SEC_TO_HOST_3_7[0-4] (PCI_CONF_SEC_TO_HOST_3_7_REGS[0-4])—Offset 4Ch, Count 5, Stride 4h" on page 3177	00000000h
60–63h	4	"DID_MSG—Offset 60h" on page 3178	00000000h
64h + [0-6]*4h	4	"PCI_CONF_HOST_TO_SEC[0-6] (PCI_CONF_HOST_TO_SEC_1_7_REGS[0-6])—Offset 64h, Count 7, Stride 4h" on page 3179	00000000h
80–83h	4	"POWERCAPID—Offset 80h" on page 3179	4803A001h
84–87h	4	"PMECTRLSTATUS—Offset 84h" on page 3180	00000008h
88–8Bh	4	"CLK_GATE_DIS—Offset 88h" on page 3181	000000FFh
8C–8Fh	4	"TPM_ICR—Offset 8Ch" on page 3182	00000000h
A0–A3h	4	"MSICAP—Offset A0h" on page 3182	00000005h
A4–A7h	4	"MSIADDR—Offset A4h" on page 3183	00000000h
A8–ABh	4	"MSIDATA—Offset A8h" on page 3183	00000000h
B0–B3h	4	"IADBGCTRL—Offset B0h" on page 3184	00000000h
B4–B7h	4	"CPU_BIOS_ENV_PROTECT—Offset B4h" on page 3185	00000000h
C0–C3h	4	"SATT_BIOS_CTRL—Offset C0h" on page 3185	00001008h
C4–C7h	4	"SATT_BIOS_BA—Offset C4h" on page 3186	00000000h
C8–CBh	4	"SATT_BIOS_SIZE—Offset C8h" on page 3187	00000000h
D0–D3h	4	"SATT_TPM_CTRL (SATT_TPM_CTRL)—Offset D0h" on page 3187	00001008h
D4–D7h	4	"SATT_TPM_BA—Offset D4h" on page 3188	00000000h
D8–DBh	4	"SATT_TPM_SIZE—Offset D8h" on page 3188	00000000h
F0–F3h	4	"URRE—Offset F0h" on page 3189	00000000h
F8–FBh	4	"MANID—Offset F8h" on page 3189	00000000h

Bit Range	Default & Access	Field Name (ID): Description
31	0b NA	RESERVED (RSVD_31_31): RESERVED BITS
30	X RW/C	SIGNALLED_SYSTEM_ERROR_30: SERR status, write 1 to clear.
29	X RW/C	RMA: SERR status, write 1 to clear.
28:21	0b NA	RESERVED (RSVD_28_21): RESERVED BITS
20	1b RO	CAPLIST: CAP: Indicates that the CAPPOINT register at 34h provides an offset into PCI Configuration Space containing a pointer to the location of the first item in the list
19	X RO	INTR_STATUS: IS: Reflects the state of the interrupt in the graphics device. Is set to 1 if interrupt (as determined by IIR and IER memory interface registers) is set to 1. Otherwise is set to 0
18:11	0b NA	RESERVED (RSVD_18_11): RESERVED BITS
10	X RW	INTR_DISABLE: ID: When 1, blocks the sending of a MSI interrupt and blocks the sending of a Message bus interrupt. The interrupt status is not blocked from being reflected in COMMANDSTATUS. INTR_STT. When 0, permits the sending of a MSI interrupt or Message bus interrupt. Note: Overall, a MSI interrupt is sent when the expression (COMMANDSTATUS. INTR_STT and ~COMMANDSTATUS. INTR_DIS and COMMANDSTATUS.BUS_MSTR_EN and MSI_CAPID.MSI_EN) changes from 0 to 1. Overall, a Message bus interrupt assert is sent when the expression (COMMANDSTATUS. INTR_STT and ~COMMANDSTATUS. INTR_DIS and ~MSI_CAPID.MSI_EN) changes from 0 to 1. The corresponding Message bus interrupt de-assert is sent when the expression (COMMANDSTATUS. INTR_STT and ~COMMANDSTATUS. INTR_DIS and ~MSI_CAPID.MSI_EN) changes from 1 to 0
9	0b NA	RESERVED (RSVD_9_9): RESERVED BITS
8	X RW	INTR_STATUS (SERR_EN_8): SERR enable.
7:3	0b NA	RESERVED (RSVD_7_3): RESERVED BITS
2	X RW	BME: BME: Enables GVD to function as a PCI compliant master. When 0, blocks the sending of MSI interrupts and DDR transactions. When 1, permits the sending of MSI interrupts and DDR transactions. Note: transactions to SEC paging IMR are not controlled (enabled/disabled) by this field
1	X RW	MSE: MSE: When set, accesses to this device's memory space is enabled. When 1, SEC will compare IOSF primary address MS bits with its BARs MS bits. If there is a match and if the IOSF command is either a MEMRD or MEMWR, SEC send the command to the destination pointed by the base address. Care should be taken in setting up SEC BARs that more than 1 match is not made as this will result in unpredictable behavior. When 0, the SEC will not select a MEMRD or MEMWR IOSF command
0	0b NA	RESERVED (RSVD_0_0): IOSE: Since SEC doesn't have I/O space, this bit is hard coded to 0. RESERVED BITS

22.3.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Revision ID and Class Code. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:26, F:0] + 8h

Default: 10800000h

Bit Range	Default & Access	Field Name (ID): Description
31:20	X RW	BaseAddressRegion: BA: Set by the OS, these bits correspond to address signals [31:20]. SEC will compare the IOSF address (bits [31:20]) with SAP_BRIDGE_BAR.BASE_ADDR. If there is a match, and COMMANDSTATUS.MEM_SPC_EN = 1 and the IOSF command is either a MEMRD or MEMWR, SEC will send the command to its MMIO registers block. If there's no MMIO register in the accessed offset, SEC Bridge will send FFFF_FFFFh to indicate a miss on the IOSF bus
19:1	0b NA	RESERVED (RSVD_19_0): RESERVED BITS
0	0b RO	RESRC_TYP: RTE: Indicates a request for memory space

22.3.7 Dummy BAR[0-3] (DUMMY_BARS[0-3])—Offset 18h, Count 4, Stride 4h

Dummy BAR, Returns zeroes to indicate un-implemented BAR. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset[0-3]: [B:0, D:26, F:0] + 18h + [0-3]*4h

Default: 00000000h

31	28	24	20	16	12	8	4	0

RSVD_31_0

Bit Range	Default & Access	Field Name (ID): Description
31:0	0b NA	RESERVED (RSVD_31_0): RESERVED BITS

22.3.8 SUBSYSTEMID—Offset 2Ch

PCI Subsystem Identifiers. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:26, F:0] + 2Ch

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
INF_PROG_CODE	CURR_PM_EV	EXT_STAT_DAT_CURR_STATE	FUNC_RSVD_15					

Bit Range	Default & Access	Field Name (ID): Description
31:28	X RW	INF_PROG_CODE: This field identifies the infrastructure progress code. For example, when firmware comes out of reset, this field would identify the infrastructure moving from ROM to BRINGUP to Micro Kernel to Policy module, etc. Note that this field is specific to infrastructure and does not represent the entire firmware. Refer to the Working State and Error Code fields to identify current state of the firmware. Values are as follows: 0: ROM. 1: Bringup. 2: uKernel. 3: Policy module. 4: Module loading. 6: Host communication. SeC is up and running, and host communication is established.
27:24	X RW	CURR_PM_EV: Status of current SeC power management event. Values as follows: 0x00: Clean M0ff --) M0 wake. 0x01: M0ff --) M0 wake after error. 0x02: Clean global reset. 0x03: Global Reset after an error. 0x04: Clean SeC reset. 0x05: SeC reset due to exception. 0x06: Pseudo-global reset. 0x07: Reserved. 0x08: Reserved. 0x09: Reserved. 0x0A: Reserved. 0x0B: Power cycle reset through M0ff. 0x0C: Reserved. 0x0D: S0/M0 --) S0/M0ff.

Bit Range	Default & Access	Field Name (ID): Description
23:16	X RW	EXT_STAT_DAT_CURR_STATE: The interpretation of this field's value depends on the value of field INF_PROG_CODE. For INF_PROG_CODE value of ROM, values are as follows: 0x000: Covers a number of steps early in ROM flow before entering main 0x001: Initialize memory map 0x002: Initialize the TPM Establishment bit 0x003: Initialize SusRAM 0x004: Get Fuse values 0x005: Derive chipset keys 0x006: Fuses/ Straps indicate ME disabled 0x007: Initialize HECI buffers 0x008: Find a FPT/Manifest image 0x009: Validate manifest found 0x00A: Load module found in manifest 0x00B: Transfer control over to new module 0x00C: Locate the FPT within memory 0x00D: Locate the Code partition within the FPT 0x00E: Initialize Paging logic 0x00F: Function designed to be patched wasn't prior to use. 0x010: H/W Page fault occurred. 0x011: Derive chipset keys For INF_PROG_CODE value of Bringup, values are as follows: 0x00: Initialization starts 0x01: Disable the host wake event 0x02: Enabling clock gating for ME 0x03: Enabling PM ME handshaking 0x04: Flow determination start process 0x05: PMC patching process 0x06: Get the flash VSCC parameters 0x07: Set (program) the flash VSCC registers 0x08: Error reading/matching the VSCC table in the descriptor 0x09: Initialize EDFS (overlay and SDM memory management) 0x0A: Check to see if straps say ME DISABLED 0x0B: Timeout waiting for T34 0x0C: Check to see if effs say ME DISABLED 0x0D: Possibly handle BUP manufacturing override strap 0x0E: Check to see if effs say ME DISABLED 0x0F: Initialize PKTPM 0x10: Initialize MiniBLOB 0x11: Bringup in M3 0x12: Bringup in M0 0x13: Flow detection error 0x14: M3 clock switching 0x15: M3 clock switching error 0x16: M3 flash paging flow 0x17: M3 ICV recovery flow 0x18: M3 kernel load 0x19: M0 Host prep sequence 0x1A: M0 Host skip prep sequence 0x1B: ICC programming 0x1C: T34 missing - Firmware is up and running.

Bit Range	Default & Access	Field Name (ID): Description
15:0	X RW	FUNC_RSVD_15: RESERVED BITS, writable

22.3.13 SEC_MEM_REQ—Offset 44h

SeC Firmware Memory Request. SeC FW uses this register in order to pass its main memory request to BIOS. Register access control: FW=RW PMC=RO Host=RO

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:26, F:0] + 44h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
MEM_REQ_VALID	MEM_REQ_INVALID	FUNC_RSVD_29_16				MEM_SIZE		

Bit Range	Default & Access	Field Name (ID): Description
31	X RW	MEM_REQ_VALID: 1: SeC is making a request for memory, the size of which is indicated by field MEM_SIZE. During early boot stages, BIOS must wait for either this bit to be set or the MEM_REQ_INVALID bit to be set before proceeding.
30	X RW	MEM_REQ_INVALID: 1: SeC is not making any request for memory, and MEM_SIZE field should be ignored. During early boot stages, BIOS must wait for either this bit to be set or the MEM_REQ_VALID bit to be set before proceeding.
29:16	X NA	FUNC_RSVD_29_16: The functionality of this field is currently reserved
15:0	X RW	MEM_SIZE: Memory size that SeC is expecting, in KB. Format is Little Endian (bit 0 least significant, bit 15 most significant).

22.3.14 SEC_FW_STS0—Offset 48h

SeC Firmware Status Register 0. SeC FW uses this register in order to report its status to host (e.g. BIOS). Register access control: FW=RW PMC=RO Host=RO

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:26, F:0] + 48h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
BIOS_MSG_ACK	ACK_DATA	FUNC_RSVD_24	SEC_RST_CNT	SEC_CURR_OPER_MODE	ERR_CODE	FW_UPD_IN_PROG	FW_BUP_LD_FLR	FW_INIT_COMP
						SEC_CURR_OP_STATE	FPT_BAD	MANUF_MODE
								SEC_CURR_WRK_STATE

Bit Range	Default & Access	Field Name (ID): Description
31:28	X RW	BIOS_MSG_ACK: DRAM Init Done ACK. 0x00: No ACK was written by SeC. 0x01: ACK was written by SeC.
27:25	X RW	ACK_DATA: DRAM Init Done ACK Data. This field contains an action which BIOS should take on receiving an ACK from SeC. 0x00: No DRAM Init Done ACK received. 0x01: Non-power cycle reset. 0x02: Power cycle reset. 0x03: Go to S3. 0x04: Go to S4. 0x05: Go to S5. 0x06: Perform Global Reset. 0x07: Continue to boot.
24	X RW	FUNC_RSVD_24: The functionality of this field is currently reserved
23:20	X RW	SEC_RST_CNT: Count of SeC Resets
19:16	X RW	SEC_CURR_OPER_MODE: The field indicates the firmware mode of operation during this boot cycle. The host must look at this field only after DRAM_INIT_DONE (DID) register based message unless the firmware is in ERR before sending the DID. The Operation Mode doesn't change at runtime. Possible values: 0: Normal. SeC is running in normal mode. 1: Reserved. 2: Debug mode. SeC firmware enters this operation mode when SeC firmware FLASH variable TBD is configured in FLASH to 1. Firmware stays in this mode until the SeC firmware FLASH variable TBD is set to 0. 3: Soft temporary disable. SeC firmware enters this operation mode when BIOS sends the Temporary Disable message to firmware. Firmware stays in this mode until BIOS sends a follow-up message to get SeC out of this mode. Entering this mode is not supported when the system is provisioned with Intel AT firmware. 4: SECOVR_JMPR: SeC firmware enters this operation mode when HDA_SDO asserts high. Asserting the HDA_SDO high on the rising edge of PWROK will also disable SeC and SeC applications. 5: SECOVR_HECI_MSG: SeC firmware enters this operation mode during the firmware image re-flash in the factory environments. BIOS sends the flash protection override message (HMRFPD ENABLE HECI command) and causes a global reset then SeC firmware stays in this state similar to 'Soft Temporary Disable'. Before sending End of Post message (at late POST timeframe), BIOS needs to send a HMRFPD DISABLE command if SECOVR_HECI_MSG is set. In the same boot, the user can flash an image and reset (global reset or G3- exit) the system that will cause firmware to boot with a normal mode.
15:12	X RW	ERR_CODE: Set to a nonzero value if the firmware has encountered a fatal error. The firmware has stopped normal operation. Encoding as follows: 0: No error. Firmware is operational in current state. 1: Uncategorized Failure. SeC firmware has experienced an uncategorized error and has disabled itself. Further details of the failure can be found in field FW_STS1.EXT_STAT_DAT. This state can only be exited by powering down or resetting the machine. 2: Reserved. 3: Image Failure. SeC firmware stored in the system flash is not valid. If supported by the platform, the host should program a full firmware image into SeC flash region through the SPI controller. After completion of the SeC flash region update, the host should generate a full system reset the platform (global reset). 4: Debug Failure. Set when more data is available to the firmware on the cause of the failure. Please refer to field FW_STS1.EXT_STAT_DAT_CURR_STATE for more details. 5: Internal ROM Error. 6: Invalid fuse configuration. 7: Failure to access SPI FLASH.
11	X RW	FW_UPD_IN_PROG: This bit is set when data migration is required during the Firmware-update process.

Bit Range	Default & Access	Field Name (ID): Description
10	X RW	FW_BUP_LD_FLR: This bit is set when firmware is not able to load BRINGUP from the fault tolerant (FT) code. When this bit set, it may or may not have the error code shown in field ERR_CODE. The reason is because the firmware can load BRINGUP from the non fault tolerant (NFT) code.
9	X RW	FW_INIT_COMP: When this bit is clear, firmware is still in loading process and has not made it to final steady state yet. When firmware has fully entered a stable state, this bit is set to 1 and 'Current Working State' field of this register provides the steady state of SeC.
8:6	000b RW	SEC_CURR_OP_STATE: This field describes the state in which SeC is currently functioning in at this moment. It's the combination of SeC power state and UMA. The field is set only upon entering the true hardware state. Values: 000b: Preboot (default) 001b: M0 with UMA. 010b: M0ff. 011b: Reserved. 100b: Reserved. 101b: Reserved. 110b: Bringup. 111b: M0 without UMA but with error. If there is no memory in the system, or upon identifying an error in UMA initialization, the SeC firmware will get into this operation state.
5	X RW	FPT_BAD: This bit is set when the firmware discovers a bad checksum of Flash Partition Table (FPT). When this bit set, it may or may not have the error code shown in field ERR_CODE. The system can get this bit clear by flashing the proper firmware image again.
4	X RW	MANUF_MODE: When this bit is set, the platform is still in Manufacturing mode. Host can use this bit to inform user that the platform is NOT ready for production yet. This bit is set as long as SeC Manufacturing Mode Done bit is set to 0 or SPI flash descriptor region is not locked. For shipping machine, this bit has to be to 0.
3:0	X RW	SEC_CURR_WRK_STATE: This field describes the current working state of the SeC firmware. Further information about the progress within the Current Working State can be found in field SEC_FW_STS1.EXT_STS_DAT. In spoken language, the 'Current Working State' indicates what firmware is doing at this moment. Encoding is as follows: 0: Reset. SeC firmware is in a reset state. 1: Initializing. SeC firmware is initializing, the final functional state is NOT known at this time. 2: Recovery: SeC firmware is recovering from an image update failure. Upon completion of this state, SeC firmware will enter the Initializing State. The firmware will stay in recovery state until a new firmware update is run. 3: Reserved. 4: Reserved. 5: Normal. SeC firmware is operating in normal state. 6: Platform Disable Wait. SeC firmware enters this state when it pauses itself with AT fuses set to halt platform after 30 minutes wait. 7: OP State Transition. SeC firmware sets this state before starting a transition to a new operation state. 8: Reserved.

22.3.15 PCI_CONF_SEC_TO_HOST_3_7[0-4] (PCI_CONF_SEC_TO_HOST_3_7_REGS[0-4])—Offset 4Ch, Count 5, Stride 4h

PCI Configuration register - SeC to Host 3-7. The functionality of this register is currently reserved. Register access control: FW=RW PMC=RO Host=RO

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset[0-4]: [B:0, D:26, F:0] + 4Ch + [0-4]*4h

Default: 00000000h

DRAM Init Done Message. BIOS uses this register in order to pass a message to SeC about the memory that it has reserved for SEC. Register access control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:26, F:0] + 60h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
DONE		STATUS		FUNC_RSVD_23_0				

Bit Range	Default & Access	Field Name (ID): Description
31:28	X RW	DONE: 0x00: DRAM Init not done. 0x01: DRAM Initialization Done. If STATUS field is success, this means that SATT1 register is set for SeC memory paging operation. Note that BIOS must not provide a DRAM Init Done message before setting up SATT1.
27:24	X RW	STATUS: 0x00: Success. 0x01: No memory in channels. 0x02: Memory Init Error.
23:0	X NA	FUNC_RSVD_23_0: RESERVED BITS

PME Control and Status. Register access control: FW=RO PMC=RW Host=RW

Type: PCI Configuration Register
(Size: 32 bits)

0	1b RW	SB_CG_DIS: IOSF Sideband Bridge clock gating disable

Bit Range	Default & Access	Field Name (ID): Description
31:16	X NA	RESERVED (Reserved_31_16): RESERVED BITS
15:0	X RW	MSGDATAMSI: MA: Lower 32-bits of the system specified message data, always DW aligned. When the SEC issues an MSI interrupt as a MEMWR on the IOSF, the memory address corresponds to the value of this field

22.3.25 IADBGCTRL—Offset B0h

IA Debug Control. Register acces control: FW=RO PMC=RW Host=RW

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:26, F:0] + B0h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31	X RO	DBG_STS: DBG_STS. This bit allows a user to be informed that their system is (or is a risk of) being debugged. It is up to the OEM/OS to act on this bit being set and find a way to expose it to the user. CLTAP will send a signal to SEC indicating that debug of the SOC and/or access to the CPUTAP is possible. This will be (allow_cputap_access dfx_security_risk). Note: DBG_STS will be set in all Opt-In cases including pre-production and IDLM.
30	X RW/1L	IADBGCTRL_LOCK: Lock. If set, writes to bits 29:0 are dropped.
29:2	0b NA	RESERVED (RSVD_29_2): RESERVED BITS
1	X RW	EXPOSE_SOCID: Expose_SOCID. If set, software is requesting that this parts unique ID will be visible in a public SOTAP register to JTAG (on-board or EXI). It is never exposed to IA code. This bit is locked (writes ignored) if the LOCK bit is set. This bit will be written but ignored if SEC OEM-M[HONOR_IADBGCTRL]=0.

Bit Range	Default & Access	Field Name (ID): Description
0	X RW	CPU_PUBLIC_DBG_EN: CPUPublicDBG_EN. If set, software is requesting access be granted to the CPUTAP's public and non-protected functions. This bit is locked (writes ignored) if the LOCK bit is set. This bit will be written but ignored if SEC OEM-M[HONOR_IADBGCTRL]=0.

22.3.26 CPU BIOS ENV PROTECT—Offset B4h

CPU BIO Environment Protection. Register access control: FW=RW PMC=RO Host=RO
Note: This register does not support byte- or word- granularity write. All 32 bits of this register should be written at once. To change only part of the register, a read-modify-write process should be used on all 32 bits

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:26, F:0] + B4h

Default: 00000000h

31	28	24	20	16	12	8	4	0

23 PCI Express* 2.0

There are four lanes and up to four PCI Express root ports, each supporting the *PCI Express* Base Specification*, Rev. 2.0 at a maximum 5 GT/s signaling rate. The root ports can be configured to support a diverse set of lane assignments.

23.1 Signal Descriptions

Please see [Chapter 2, “Physical Interfaces”](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal’s function

Note: PMC_WAKE_PCIE[3:0]# are not listed, but can be used by PCI Express* devices. Please see [Section 30, “PCU – Power Management Controller \(PMC\)”](#) on page 4344 for details.

Table 240. Signals

Signal Name	Direction Plat. Power	Description
PCIE_TXP[3:0] PCIE_TXN[3:0]	O PCIESATA	PCI Express* Transmit PCI Express* Ports 3:0 transmit pair (P and N) signals. Each pair makes up the transmit half of a lane.
PCIE_RXP[3:0] PCIE_RXN[3:0]	I PCIESATA	PCI Express* Receive: PCI Express* Ports 3:0 receive pair (P and N) signals. Each pair makes up the receive half of lane.
PCIE_CLKP[3:0] PCIE_CLKN[3:0]	O V1P0S	PCI Express* Output Clock 100-MHz differential clock signals. These are not owned by the PCI Express* controller, but are platform clocks found in the Integrated Clock.
PCIE_CLKREQ[3:0]#	I V1P8S	PCI Express* Clock Request Used for devices that need to request one of the four output clocks. Each clock request maps to the matching clock output (e.g., PCIE_CLKREQ[0] maps to PCIE_CLKP/N[0]). These are not owned by the PCI Express* controller, but are platform clocks found in the Integrated Clock. <i>These signals are muxed and may be used by other functions.</i>
PCIE_RCOMP_P PCIE_RCOMP_N	I/O	These pins are used to connect the external resistors used for Rcomp. Please contact your Intel representative for details.

Figure 112. PCIe* 2.0 Lane 0 Signal Example

23.2 Features

- Conforms to *PCI Express* Base Specification, Rev. 2.0*
- 5.0 or 2.5 GT/s operation per root port
- Virtual Channel support for VC0
- x1, x2 and x4 link widths (auto negotiated)
- Flexible Root Port (1-4) configuration options
 - (4) x1's

- (2) x2's
- (1) x2 plus (2) x1's
- (1) x4
- Interrupts and Events
 - Legacy (INTx) and MSI Interrupts
 - General Purpose Events
 - Express Card Hot Plug Events
 - System Error Events
- Power Management
 - Link State support for L0s, L1 and L2
 - Powered down in ACPI S3 state - L3

23.2.1 Root Port Configurations

Depending on SKU, there are up to four possible lane assignments for root ports 1-4.

Figure 113. Root Port Configuration Options

Root port configurations are set by SoftStraps stored in SPI flash, and the default option is "(4) x1". Links for each root port will train automatically to the maximum possible for each port.

Note: x2 link widths are not common. Most devices will only train to x1 or x4.

Note: PCI functions in PCI configuration space are disabled for root ports not available.

23.2.2 Interrupts and Events

A root port is capable of handling interrupts and events from an end point device. A root port can also generate its own interrupts for some events, including power management and hot plug events, but also including error events.

There are two interrupt types a root port will receive from an end point device: INTx (legacy), and MSI. MSI's are automatically passed upstream by the root port, just as other memory writes would be. INTx messages are delivered to the Legacy block's interrupt router/controller by the root port.

Events and interrupts that are handled by the root port are shown with the possible interrupts they can deliver to the interrupt decoder/router.

Table 241. Possible Interrupts Generated From Events/Packets

Packet/Event	Type	INTx	MSI	SERR	SCI	SMI	GPE
INTx	Packet	X	X				
PM_PME	Packet	X	X				
Power Management (PM)	Event	X	X		X	X	
Hot Plug (HP)	Event	X	X		X	X	
ERR_CORR	Packet			X			
ERR_NONFATAL	Packet			X			
ERR_FATAL	Packet			X			
Internal Error	Event			X			
VDM	Packet						X

Note: Table 241 lists the possible interrupts and events generated based on Packets received, or events generated in the root port. Configuration needed by software to enable the different interrupts as applicable.

When INTx interrupts are received by an end point, they are mapped to the following interrupts and sent to the interrupt decoder/router in the iLB:

Table 242. Interrupt Generated for INT[A-D] Interrupts

	INTA	INTB	INTC	INTD
Root Port 1	INTA#	INTB#	INTC#	INTD#
Root Port 2	INTD#	INTA#	INTB#	INTC#
Root Port 3	INTC#	INTD#	INTA#	INTB#
Root Port 4	INTB#	INTC#	INTD#	INTA#

Note: Interrupts generated from events within the root port are not swizzled.

23.2.2.1 Express Card Hot Plug Events

Express Card Hot Plug is available based on Presence Detection for each root port.

Note: A full Hot Plug Controller is not implemented.

Presence detection occurs when a PCI Express* device is plugged in and power is supplied. The physical layer will detect the presence of the device, and the root port will set the SLSTS.PDS and SLSTS.PDC bits.

When a device is removed and detected by the physical layer, the root port will clear the SLSTS.PDS bit, and set the SLSTS.PDC bit.

Interrupts can be generated by the root port when a hot plug event occurs. A hot plug event is defined as the transition of the SLSTS.PDC bit from 0 to 1. Software can set the SLCTL.PDE and SLTCTL.HPE bits to allow hot plug events to generate an interrupt.

If SLCTL.PDE and SLTCTL.HPE are both set, and SLSTS.PDC transitions from 0 to 1, an interrupt will be generated.

23.2.2.2 System Error (SERR)

System Error events are support by both internal and external sources. See the PCI Express* Base Specification, Rev. 2.0 for details.

23.2.3 Power Management

Each root port's link supports L0s, L1, and L2/3 link states per PCI Express* Base Specification, Rev. 2.0. L2/3 is entered on entry to S3.

23.3 References

PCI Express Base Specification, Rev. 2.0*

23.4 Register Map

Each root port supports its own extended PCI bridge header in PCI configuration space. These headers are located on PCI bus 0, device 28, functions 0-3 as shown below. There are no other registers implemented by the root ports or their controller.

See Chapters [Chapter 3, "Register Access Methods"](#) and [Chapter 4, "Mapping Address Spaces"](#) for additional information.

Figure 114. PCI Express Register Map

23.5 PCI Configuration Registers

Registers listed are for function 0 (root port 1). All other root ports contain the same registers. Differences for other root ports (functions 1-3) will be noted in individual registers.

23.6.2 Device Command; Primary Status (CMD_PSTS)—Offset 4h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

CMD_PSTS: [B:0, D:28, F:0] + 4h

Power Well: Core

Default: 00100000h

31		28				24				20				16				12				8				4				0																							
0		0		0		0		0		0		0		1		0		0		0		0		0		0		0		0		0																					
DPE		SSE		RMA		RTA		STA		PDTS		DPD		PFBC		RSVD		PC66		CLIST		IS		RSVD_1				RSVD_2				ID		FBE		SEE		WCC		PERE		VGA_PSE		MWIE		SCE		BME		MSE		TOSF	

Bit Range	Default & Access	Description
31	0b RW/C	DPE Detected Parity Error (DPE): Set when the root port receives a command or data from the backbone with a parity error. This is set even if CMD.PERE is not set.
30	0b RW/C	Signaled System Error (SSE): Set when the root port signals a system error to the internal SERR# logic.
29	0b RW/C	Received Master Abort (RMA): Set when the root port receives a completion with unsupported request status from the backbone.
28	0b RW/C	Received Target Abort (RTA): Set when the root port receives a completion with completer abort from the backbone.
27	0b RW/C	Signaled Target Abort (STA): Set whenever the root port forwards a target abort received from the downstream device onto the backbone.
26:25	00b RO	Primary DEVSEL# Timing Status (PSTS): Reserved per PCI-Express spec
24	0b RW/C	Master Data Parity Error Detected (DPD): Set when the root port receives a completion with a data parity error on the backbone and CMD.PERE is set.
23	0b RO	Primary Fast Back to Back Capable (PFBC): Reserved per PCI-Express spec.
22	0b RO	Reserved (RSVD): Reserved
21	0b RO	Primary 66 MHz Capable (PC66): Reserved per PCI-Express spec.
20	1b RO	Capabilities List (CLIST): Indicates the presence of a capabilities list.
19	0b RO/V	Interrupt Status (IS): Indicates status of hot plug and power management interrupts on the root port that result in INTx# message generation. This bit is not set if MSI is enabled. If MSI is not enabled, this bit is set regardless of the state of CMD.ID.
18:16	000b RO	Reserved (RSVD_1): Reserved
15:11	00h RO	Reserved (RSVD_2): Reserved

Bit Range	Default & Access	Description
10	0b RW/V	Interrupt Disable (ID): This disables pin-based INTx# interrupts on enabled hot plug and power management events. This bit has no effect on MSI operation. When set, internal INTx# messages will not be generated. When cleared, internal INTx# messages are generated if there is an interrupt for hot plug or power management and MSI is not enabled. This bit does not affect interrupt forwarding from devices connected to the root port. Assert_INTx and Deassert_INTx messages will still be forwarded to the internal interrupt controllers if this bit is set. For PCI Bus Emulation Mode compatibility, if the PCIBEM register is set, this register is RO and returns a value of 0 when read, else it is RW with the functionality described above.
9	0b RO	Fast Back to Back Enable (FBE): Reserved per PCI-Express spec.
8	0b RW	SERR# Enable (SEE): When set, enables the root port to generate an SERR# message when PSTS.SSE is set.
7	0b RO	Wait Cycle Control (WCC): Reserved per PCI-Express spec.
6	0b RW	Parity Error Response Enable (PERE): Indicates that the device is capable of reporting parity errors as a master on the backbone.
5	0b RO	VGA Palette Snoop (VGA_PSE): Reserved per PCI-Express spec.
4	0b RO	Memory Write and Invalidate Enable (MWIE): Reserved per PCI-Express spec.
3	0b RO	Special Cycle Enable (SCE): Reserved per PCI-Express and PCI bridge spec.
2	0b RW	Bus Master Enable (BME): When set, allows the root port to forward Memory and I/O Read/Write cycles onto the backbone from a PCI-Express device. When this bit is 0b, Memory and I/O requests received at a Root Port must be handled as Unsupported Requests (UR). This bit does not affect forwarding of Completions in either the Upstream or Downstream direction. The forwarding of Requests other than Memory or I/O requests is not controlled by this bit.
1	0b RW	Memory Space Enable (MSE): When set, memory cycles within the range specified by the memory base and limit registers can be forwarded to the PCI-Express device. When cleared, these memory cycles are master aborted on the backbone.
