**Notes:**

- 1) Exceeding these ratings may damage the device.
- 2) The maximum allowable power dissipation depends on the schottky's thermal run away point, the junction-to-ambient thermal resistance θ<sub>JA</sub>, and the ambient temperature T<sub>A</sub>. The maximum allowable continuous power dissipation is different at different ambient temperature. Exceeding the maximum allowable power dissipation will cause excessive die temperature and permanent damage. Please refer to the derating operation curve in TYPICAL PERFORMANCE CHARACTERISTICS.
- 3) Devices are ESD sensitive. Handling precaution recommended.
- 4) The device is not guaranteed to function outside of its operating conditions.
- 5) Measured on JESD51-7, 4-layer PCB.

## OPERATION

The MP8051 is a monolithic switch bridge regulator to regulate the input square waveform to the DC output.

Compared against conventional 4-diode silicon bridge regulators, the two integrated MOSFETs reduce power loss by implementing soft switching. These two MOSFETs (M1 and M2) are driven from the input signals (refer to Figure1).

The MP8051 takes a square wave input. When L1 initially receives the positive input and L2 the negative input, current initially flows through the

M1 parasitic diode, D1. Then Drive1 generates the turn on signal for the rest of the device.

When the square wave signal inverts, the Drive1 turns off M1 while D1 continues to conduct for soft switching. Then D2, M2, and Drive2 follow the same process.

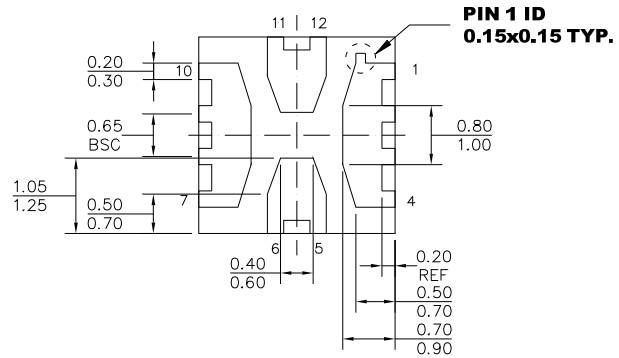

Both Drive1 and Drive2 clamp the driving signals of the two low-side MOSFETs below 6.5V when the voltage difference between L1 and L2 exceeds 6.5V.
