1	00003H	X or L	INT0
2	0000BH	X or L	INT1
3	00013H	H or L	INT2/T0L/INT4/UHC-A bus active/UHC-B bus active/USB bus active/remote control receive

    • Low voltage detection reset (LVD) function

        <1> LVD and POR functions are combined to generate resets when power is turned on and when power voltage falls below a threshold level.

        <2> The use/disuse of the LVD function and the low voltage threshold level (7 levels: 1.91V, 2.01V, 2.31V, 2.51V, 2.81V, 3.79V, and 4.28V) can be selected by setting options.

■ Standby Function

        - <4> Establishing an interrupt source at port 0
        - <5> Establishing an bus active interrupt source in the USB host control circuit

- X'tal HOLD mode : Suspends instruction execution and the operation of the peripheral circuits except the base timer and infrared remote control receiver circuit.
    - (1) The PLL, CF and RC oscillators automatically stop operation.
        - Note : Low-speed RC oscillator is controlled directly by the watchdog timer and its oscillation in standby mode is also controlled.
        - Note : The low-speed RC oscillator retains the state that is established on entry into X'tal HOLD mode if the base timer is running with the low-speed RC oscillator selected as the base timer input clock source.
    - (2) The state of crystal oscillator established when the X'tal HOLD mode is entered is retained.
    - (3) There are seven ways of releasing X'tal HOLD mode.
        - <1> Setting the reset pin to a low level
        - <2> Generating a reset signal by the watchdog timer or low-voltage detection
        - <3> Establishing an interrupt source at one of INT0, INT1, INT2, INT4, and INT5 pins
            - * INT0 and INT1 X'tal HOLD mode release is available only when level detection is configured.
        - <4> Establishing an interrupt source at port 0
        - <5> Establishing an interrupt source in the base timer circuit
        - <6> Establishing an interrupt source in the infrared remote control receiver circuit
        - <7> Establishing an bus active interrupt source in the USB host control circuit

USB Reference Power Option

When a voltage 4.5 to 5.5V is supplied to $V_{DD}1$ and the internal USB reference voltage circuit is activated, the reference voltage for USB port output is generated. The active/inactive state of the reference voltage circuit can be switched by selecting an option. The procedure for making the option selection is described below.

		(1)	(2)	(3)	(4)
Option settings	USB regulator	Use	Use	Use	Non-use
	USB regulator at HOLD mode	Use	Non-use	Non-use	Non-use
	USB regulator at HALT mode	Use	Non-use	Use	Non-use
Reference voltage circuit state	Normal mode	Active	Active	Active	Inactive
	HOLD mode	Active	Inactive	Inactive	Inactive
	HALT mode	Active	Inactive	Active	Inactive

• When the USB reference voltage circuit is made inactive, the level of the reference voltage for the USB port output is equal to $V_{DD}1$.
• Selection (2) or (3) can be used to set the reference voltage circuit inactive in HOLD or HALT mode.
• When the reference voltage circuit is activated, the current drain increases by approximately 100μA compared with when the reference voltage circuit is inactive.

Example 1 : $V_{DD}1=V_{DD}2=3.3V$
  • Inactivating the reference voltage circuit (selection (4)).
  • Connecting $V_{DD}3$ to $V_{DD}1$ and $V_{DD}2$.
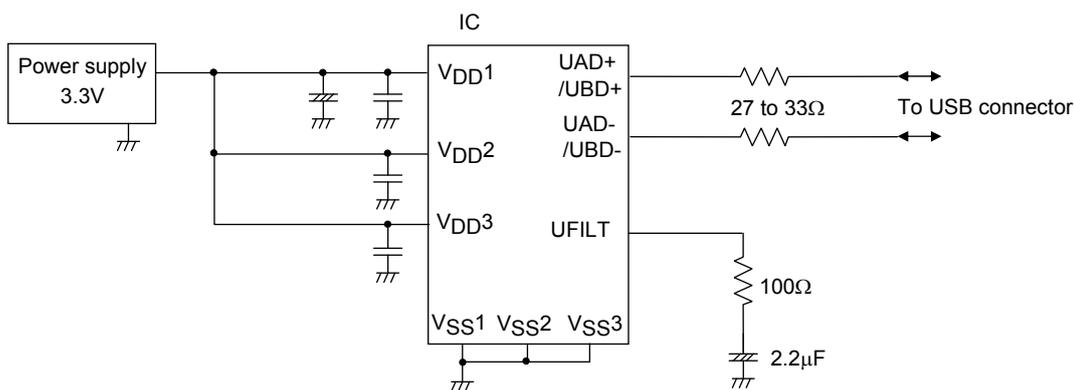

Example 2 : $V_{DD}1=V_{DD}2=5.0V$
  • Activating the reference voltage circuit (selection (1)).
  • Isolating $V_{DD}3$ from $V_{DD}1$ and $V_{DD}2$, and connecting capacitor between $V_{DD}3$ and V_{SS}.
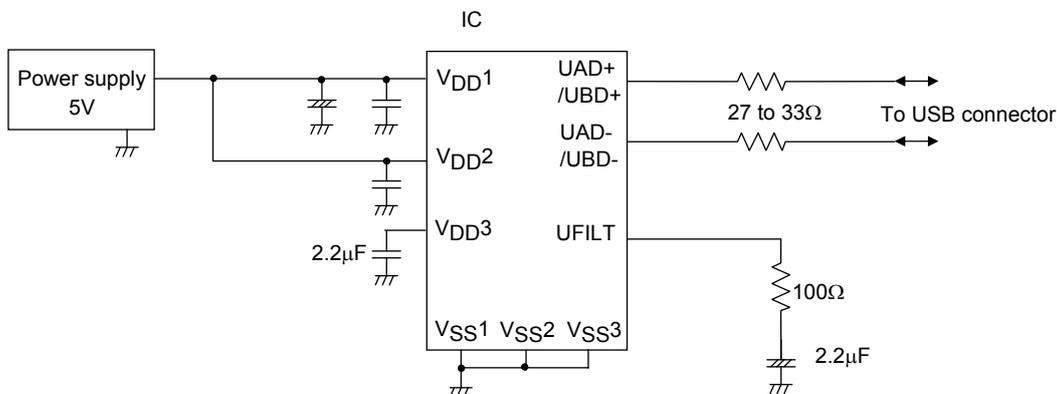

Note : Do not apply the voltage of more than 3.6V to UAD+, UAD−, UBD+ and UBD− when the reference voltage circuit is active.

Note 4-5-1 : These specifications are theoretical values. Margins must be allowed according to the actual operating conditions.

Note 4-5-2 : The value of Tfilt is determined by bits 7 and 6 (BRP1 and BRP0) of the SMIC0BRG/SMIC1BRG register and the system clock frequency.

BRP1	BRP0	Tfilt
0	0	(1/3) tCYC×1
0	1	(1/3) tCYC×2
1	0	(1/3) tCYC×3
1	1	(1/3) tCYC×4

Set the value of the BRP1 and BRP0 bits so that the value of Tfilt falls within the following value range :

250 ns ≥ Tfilt > 140 ns

Note 4-5-3: For standard clock mode operation, set up the SMIC0BRG/SMIC1BRG register so that the following conditions are satisfied :

250 ns ≥ Tfilt > 140 ns

BRDQ (bit5) = 1

SCL frequency value ≤ 100 kHz

For high-speed clock mode operation, set up the SMIC0BRG/SMIC1BRG register so that the following conditions are satisfied :

250 ns ≥ Tfilt > 140 ns

BRDQ (bit5) = 0

SCL frequency value ≤ 400 kHz

Note 6-2: The conversion time refers to the period from the time an instruction for starting a conversion process until the time the conversion result register is loaded with a complete digital conversion value corresponding to the analog input value.

The conversion time is doubled in the following cases :

- The AD conversion is carried out in the 12-bit AD conversion mode for the first time after a system reset.

- The AD conversion is carried out for the first time after the AD conversion mode is switched from 8-bit to 12-bit AD conversion mode.

Main System Clock Oscillation

The characteristics of a sample main system clock oscillator circuit shown in Table 1 are measured using an our oscillation characteristics evaluation board and external components with circuit constant values with which the resonator vendor confirmed normal and stable oscillation.

Table 1 shows the characteristics of a oscillator circuit when USB host function is not used. If USB host function is to be used, it is absolutely recommended to use a resonator that satisfies the precision and stability according to the USB standards (±500ppm)

Table 1   Characteristics of a Sample Main System Clock Oscillator Circuit with a Ceramic Resonator

Nominal Frequency	Vendor Name	Resonator Name	Circuit Constant			Operating Voltage Range [V]	Oscillation Stabilization Time		Remarks
			C1 [pF]	C2 [pF]	Rd1 [Ω]		typ [ms]	max [ms]	
12MHz	MURATA	CSTCE12M0GH5L**-R0	(33)	(33)	470	3.0 to 5.5	0.1	0.5	C1 and C2 integrated SMD type

The oscillation stabilization time is required for the oscillator to get stabilized in the following cases (see Figure 4):

· Until oscillation is stabilized after V_{DD} goes above the operating voltage lower limit

· Until oscillation is stabilized after the instruction for starting the main clock oscillator circuit is executed

· Until oscillation is stabilized after HOLD mode is released.

· Until oscillation is stabilized after X'tal HOLD mode is released with CFSTOP (OCR register, bit 0) set to 0 and oscillation is started.

Subsystem Clock Oscillation

Table 2 shows the characteristics of a sample subsystem clock oscillator circuit that are measured using an our oscillation characteristics evaluation board and external components with circuit constant values with which the resonator vendor confirmed normal and stable oscillation.

Table 2   Characteristics of a Sample Subsystem Clock Oscillator Circuit with a Crystal Resonator

32.768kHz	EPSON TOYOCOM	MC-306	18	18	Open	680k	2.7 to 5.5	1.1	3.0	Applicable CL value=12.5pF SMD type

The oscillation stabilization time is required for the oscillator to get stabilized in the following cases (see Figure 4) :
· Until oscillation is stabilized after the instruction for starting the subclock oscillator circuit is executed
· Until oscillation is stabilized after HOLD mode is released with EXTOSC (OCR register, bit 6) set to 1 and oscillation is started.

Note : The components that are involved in oscillation should be placed as close to the IC and to one another as possible because they are vulnerable to the influences of the circuit pattern.

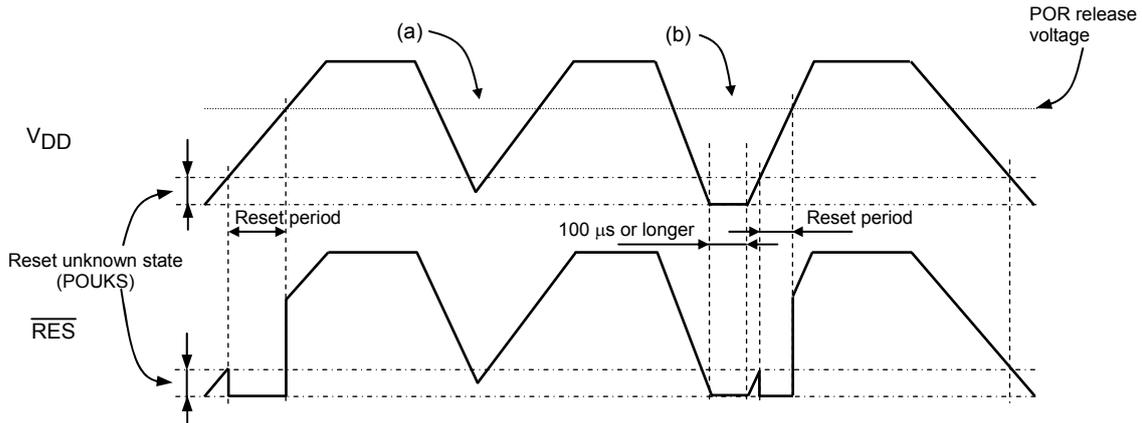

Figure 12   Sample Waveforms for POR-only (LVD deselected) Operation (Reset pin : Pull-up resistor P_{RES} only)

• The POR function generates a reset only when the power is turned on starting at the V_{SS} level.
• No stable reset will be generated if power is turned on again if the power level does not go down to the V_{SS} level as shown in (a). If such a case is anticipated, use the LVD function together with the POR function as explained below or implement an external reset circuit.
• A reset is generated only when power level goes down to the V_{SS} level as shown in (b) and power is turned on again after this condition continues for 100 μs or longer.

• A reset is generated both when power is turned on and when the power level lowers.
• A hysteresis width (LVHYS) is provided to prevent repetitions of reset release and entry cycles near the detection level.
