

MCP41HVX1

7/8-Bit Single, +36V (±18V) Digital POT with SPI Serial Interface and Volatile Memory

Features

- High-Voltage Analog Support:
 - +36V Terminal Voltage Range (DGND = V-)
 - ±18V Terminal Voltage Range
 - (DGND = V- + 18V)
- Wide Operating Voltage:
 - Analog: 10V to 36V (specified performance)
 - Digital: 2.7V to 5.5V
 - 1.8V to 5.5V (DGND \ge V- + 0.9V)
- Single Resistor Network
- Potentiometer Configuration Options
- Resistor Network Resolution
 - 7-bit: 127 Resistors (128 Taps)
 - 8-bit: 255 Resistors (256 Taps)
- R_{AB} Resistance Options:
 - 5 kΩ 10 kΩ
 - 50 kΩ 100 kΩ
- High Terminal/Wiper Current (I_W) Support:
 - 25 mA (for 5 kΩ)
 - 12.5 mA (for 10 kΩ)
- 6.5 mA (for 50 kΩ and 100 kΩ)
- · Zero-Scale to Full-Scale Wiper Operation
- Low Wiper Resistance: 75 Ω (Typical)
- · Low Tempco:
 - Absolute (Rheostat): 50 ppm Typical (0°C to +70°C)
 - Ratiometric (Potentiometer): 15 ppm Typical
- SPI Serial Interface (10 MHz, Modes 0, 0 and 1, 1)
- Resistor Network Terminal Disconnect Via:
 - Shutdown Pin (SHDN)
 - Terminal Control (TCON) Register
- Write Latch (WLAT) Pin to control update of Volatile Wiper Register (such as Zero Crossing)
- Power-On Reset / Brown-Out Reset for both:
 - Digital Supply (V_L/DGND); 1.5V Typical
 - Analog Supply (V+ / V-); 3.5V Typical
- Serial Interface Inactive Current (3 µA Typical)
- 500 kHz Typical Bandwidth (-3 dB) Operation (5.0 kΩ Device)
- Extended Temperature Range (-40°C to +125°C)
- Package Types: TSSOP-14 and QFN-20 (5x5)

Description

The MCP41HVX1 family of devices have dual power rails (analog and digital). The analog power rail allows high voltage on the resistor network terminal pins. The analog voltage range is determined by the V+ and V– voltages. The maximum analog voltage is +36V, while the operating analog output minimum specifications are specified from either 10V or 20V. As the analog supply voltage becomes smaller, the analog switch resistances increase, which effect certain performance specifications. The system can be implemented as dual rail (±18V) relative to the digital logic ground (DGND).

The device also has a Write Latch (\overline{WLAT}) function, which will inhibit the volatile wiper register from being updated (latched) with the received data, until the \overline{WLAT} pin is low. This allows the application to specify a condition where the volatile wiper register is updated (such as zero crossing).

MCP41HVX1

Device Block Diagram

Device Features

Dovico	Pavies 0 Wiper		trol face	Wiper ting	Resistance (Number of:		Specified Operating Range		
Device	# of I	Configuration	Con Inter	POR Sett	R _{AB} Options (kΩ)	Wiper- R _W (Ω)	Rs	Taps	V _L (<mark>2</mark>)	V+ ⁽ 3)
MCP41HV31	1	Potentiometer (1)	SPI	3Fh	5.0, 10.0, 50.0, 100.0	75	127	128	1.8V to 5.5V	10V (4) to 36V
MCP41HV51	1	Potentiometer (1)	SPI	7Fh	5.0, 10.0, 50.0, 100.0	75	255	256	1.8V to 5.5V	10V (4) to 36V

Note 1: Floating either terminal (A or B) allows the device to be used as a Rheostat (variable resistor).

2: This is relative to the DGND signal. There is a separate requirement for the V+ / V- voltages. When V_L = 1.8V operation, DGND must be 0.9V above V-.

3: Relative to V-, the V_L and DGND signals must be between V- and V+.

4: Analog operation will continue while the V+ voltage is above the device's Analog Power-on Reset (POR) / Brown-out Reset (BOR) voltage. Operational characteristics may exceed specified limits while the V+ voltage is below the specified minimum voltage.

1.0 ELECTRICAL CHARACTERISTICS

Absolute Maximum Ratings †

Voltage on V- with respect to DGND	DGND + 0.6V to -40.0V
Voltage on V+ with respect to DGND	
Voltage on V+ with respect to V-	DGND - 0.3V to 40.0V
Voltage on V _L with respect to V+	-0.6V to -40.0V
Voltage on V _L with respect to V	-0.6V to +40.0V
Voltage on V _L with respect to DGND	-0.6V to +7.0V
Voltage on CS, SCK, SDI, WLAT, and SHDN with respect to DGND	-0.6V to V _L + 0.6V
Voltage on all other pins (PxA, PxW, and PxB) with respect to V	-0.3V to V+ + 0.3V
Input clamp current, I_{IK} (V _I < 0, V _I > V _L , V _I > V _{PP} on HV pins)	±20 mA
Output clamp current, I_{OK} (V _O < 0 or V _O > V _L)	±20 mA
Maximum current out of DGND pin	100 mA
Maximum current into V _L pin	100 mA
Maximum current out of V- pin	100 mA
Maximum current into V+ pin	
Maximum current into PxA, PxW, & PxB pins (Continuous) $R_{AB} = 5 k\Omega$ $R_{AB} = 10 k\Omega$ $R_{AB} = 50 k\Omega$ $R_{AB} = 100 k\Omega$	
Maximum current into PxA, PxW, & PxB pins (Pulsed) $F_{PULSE} > 10 \text{ kHz}$ $F_{PULSE} \leq 10 \text{ kHz}$	
Maximum output current sunk by any Output pin	
Maximum output current sourced by any Output pin	25 mA
Package Power Dissipation (T _A = + 50°C, T _J = +150°C) TSSOP-14 SOIC-16 QFN-20 (5 x 5) QFN-20 (4x4)	
Soldering temperature of leads (10 seconds)	+300°C
ESD protection on all pins Human Body Model (HBM) Machine Model (MM)	$\geq \pm 4 \text{ kV}$
Maximum Junction Temperature (T _J) Storage temperature Ambient temperature with power applied	

† Notice: Stresses above those listed under "Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

AC/DC CHARACTERISTICS

Resistor Network Supply Voltage	V _{RN}	—	—	36V	V	Delta voltage between V+ and V- (Note 4)					
V _L Start Voltage to ensure Wiper Reset	V _{DPOR}	—	_	1.8	V	With respect to DGND, V+ > $6.0V$ RAM retention voltage (V _{RAM}) < V _{DBOR}					
V+ Voltage to ensure Wiper Reset	V _{APOR}	_		6.0	V	With respect to V-, $V_L = 0V$ RAM retention voltage (V_{RAM}) < V_{BOR}					
Digital to Analog Level Shifter Operational Voltage	V_{LS}	_		2.3	V	V _L to V- voltage. DGND = V-					
Power Rail Voltages during Power Up (Note 1)	V _{LPOR}			5.5	V	Digital Powers (V _L / DGND) up 1st: V+ and V- floating or as V+ / V- powers up (V+ must be \geq to DGND) (Note 18)					
	V+ _{POR}		_	36	V	Analog Powers (V+ / V-) up 1st: V_L and DGND floating or as V_L / DGND powers up (DGND must be between V- and V+) (Note 18)					
V _L Rise Rate to ensure Power-on Reset	V _{LRR}	1)	Note 6)	V/ms	With respect to DGND					

Note 1 This specification by design.

Note 4 V+ voltage is dependent on V- voltage. The maximum delta voltage between V+ and V- is 36V. The digital logic DGND potential can be anywhere between V+ and V-, the V_L potential must be \geq DGND and \leq V+.

Note 5 Minimum value determined by maximum V- to V+ potential equals 36V and minimum $V_L = 1.8V$ for operation. So 36V - 1.8V = 34.2V.

Note 6 POR/BOR is not rate dependent.

Note 16 For specified analog performance, V+ must be 20V or greater (unless otherwise noted).

Note 18 During the power up sequence, to ensure expected Analog POR operation, the two power systems (Analog and Digital) should have a common reference to ensure that the driven DGND voltage is not at a higher potential than the driven V+ voltage.

			0.0015	0.0035	%/%	7-bit	V _L = 2.7V to 5.5V, V+ = 18V, V- = -18V, Code = 3Fh			
Power Dissipation	P _{DISS}	—	260	—	mW	5 kΩ	V _L = 5.5V, V+ = 18V, V- = -18V			
			130		mW	10 kΩ	(Note 15)			
		—	26	—	mW	50 kΩ				
			13		mW	100 k Ω				

Note 15 $P_{DISS} = I * V$, or ($(I_{DDD} * 5.5V) + (I_{DDA} * 36V) + (I_{AB} * 36V)$).

AC / DC Notes:

- 1. This specification by design.
- 2. This parameter is not tested, but specified by characterization.
- 3. See Absolute Maximum Ratings.
- 4. V+ voltage is dependent on V- voltage. The maximum delta voltage between V+ and V- is 36V. The digital logic DGND potential can be anywhere between V+ and V-, the V_L potential must be >= DGND and <= V+.</p>
- 5. Minimum value determined by maximum V- to V+ potential equals 36V and minimum V_L = 1.8V for operation. So 36V 1.8V = 34.2V.
- 6. POR/BOR is not rate dependent.
- 7. Supply current (I_{DDD} and I_{DDA}) is independent of current through the resistor network.
- 8. Resistance (R_{AB}) is defined as the resistance between Terminal A to Terminal B.
- 9. Guaranteed by the R_{AB} specification and Ohms Law.
- 10. Measured at V_W with $V_A = V+$ and $V_B = V-$.
- 11. Resistor terminals A, W and B's polarity with respect to each other is not restricted.
- 12. Non-linearity is affected by wiper resistance (R_W), which changes significantly over voltage and temperature.
- 13. Externally connected to a Rheostat configuration (R_{BW}), and then tested.
- Wiper current (I_W) condition determined by R_{AB(max)} and Voltage Condition, the delta voltage between V+ and V-(voltages are 36V, 20V, and 10V).
- 15. $P_{DISS} = I * V$, or ($(I_{DDD} * 5.5V) + (I_{DDA} * 36V) + (I_{AB} * 36V)$).
- 16. For specified analog performance, V+ must be 20V or greater (unless otherwise noted).
- 17. Analog switch leakage effects this specification. Higher temperatures increase the switch leakage.
- 18. During the power up sequence, to ensure expected Analog POR operation, the two power systems (Analog and Digital) should have a common reference to ensure that the driven DGND voltage is not at a higher potential than the driven V+ voltage.

Temperature Ranges								
Specified Temperature Range	Τ _Α	-40	_	+125	°C			
Operating Temperature Range	T _A	-40		+125	°C			
Storage Temperature Range	T _A	-65		+150	°C			
Thermal Package Resistances								
Thermal Resistance, 14L-TSSOP (ST)	θ_{JA}	—	100		°C/W			
Thermal Resistance, 20L-QFN (MQ)	θ_{JA}	_	36.1		°C/W			

2.0 TYPICAL PERFORMANCE CURVES

Note: The device Performance Curves are available in a separate document. This is done to keep the file size of this PDF document less than the 10MB file attachment limit of many mail servers. The MCP41HVX1 Performance Curves document is literature number DS20005209, and can be found on the Microchip website. Look at the MCP41HVX1 Product Page under Documentation and Software, in the Data Sheets category.

MCP41HVX1

NOTES:

3.0 **PIN DESCRIPTIONS**

The descriptions of the pins are listed in Table 3-1. Additional descriptions of the device pins follows.

TABLE 3-1: PINOUT DESCRIPTION FOR THE MCP41HVX1

		Pin			
TSSOP	QFN	Ourseland	T	Buffer	Function
14L	20L	Symbol	Туре	Туре	
1	1	VL	Р	_	Positive Digital Power Supply Input
2	2	SCK	I	ST	SPI Serial Clock pin
3	3	CS	I	ST	Chip Select
4	4	SDI	I	ST	SPI Serial Data In pin
5	5	SDO	0	_	SPI Serial Data Out
6	6	WLAT	I	ST	 Wiper Latch Enable 0 = Received SPI Shift Register Buffer (SPIBUF) value is transferred to Wiper register. 1 = Received SPI data value is held in SPI Shift Register Buffer (SPIBUF).
7	7	SHDN	I	ST	Shutdown
8	11	DGND	Р	_	Ground
9	8, 9, 10, 17, 18, 19, 20	NC	-	—	Pin not internally connected to die. To reduce noise coupling, connect pin either to DGND or V_L .
10	12	V-	Р	_	Analog Negative Potential Supply
11	13	P0B	I/O	А	Potentiometer 0 Terminal B
12	14	P0W	I/O	A	Potentiometer 0 Wiper Terminal
13	15	P0A	I/O	А	Potentiometer 0 Terminal A
14	16	V+	Р	_	Analog Positive Potential Supply
-	21	EP	Р	_	Exposed Pad, connect to V- signal or Not Connected (floating). (Note 1)
Legend:	A = Ana	alog S	ST = Sch	mitt Trigge	r
	l = Inpu	t () = Outp	out	I/O = Input/Output P = Power

Note 1: The QFN package has a contact on the bottom of the package. This contact is conductively connected to the die substrate, and therefore should be unconnected or connected to the same ground as the device's V- pin.

3.1 Positive Power Supply Input (V_L)

The V_L pin is the device's positive power supply input. The input power supply is relative to DGND and can range from 1.8V to 5.5V. A de-coupling capacitor on V_L (to DGND) is recommended to achieve maximum performance.

While the device's $V_L < V_{min}$ (2.7V), the electrical performance of the device may not meet the data sheet specifications.

3.2 Serial Clock (SCK)

The SCK pin is the serial interface's Serial Clock pin. This pin is connected to the host controllers SCK pin. The MCP41HVX1 is an SPI slave device, so its SCK pin is an input only pin.

3.3 Chip Select (CS)

The \overline{CS} pin is the serial interface's chip select input. Forcing the \overline{CS} pin to V_{II} enables the serial commands.

3.4 Serial Data In (SDI)

The SDI pin is the serial interfaces Serial Data In pin. This pin is connected to the host controller's SDO pin.

3.5 Serial Data Out (SDO)

The SDO pin is the serial interface's Serial Data Out pin. This pin is connected to the host controller's SDI pin.

This pin allows the host controller to read the digital potentiometer registers (Wiper and TCON), or monitor the state of the command error bit.

3.6 Wiper Latch (WLAT)

The \overline{WLAT} pin is used to hold off the transfer of the received wiper value (in the shift register) to the wiper register. This allows this transfer to be synchronized to an external event (such as zero crossing).

3.7 Shutdown (SHDN)

The $\overline{\text{SHDN}}$ pin is used to force the resistor network terminals into the hardware shutdown state.

3.8 Digital Ground (DGND)

The DGND pin is the device's Digital ground reference.

3.9 Not Connected (NC)

This pin is not internally connected to the die. To reduce noise coupling, these pins should be connected to either V_L or DGND.

3.10 Analog Negative Voltage (V-)

Analog circuitry negative supply voltage. Must **not** have a higher potential then the DGND pin.

3.11 Potentiometer Terminal B

The terminal B pin is connected to the internal potentiometer's terminal B.

The potentiometer's terminal B is the fixed connection to the zero scale wiper value of the digital potentiometer. This corresponds to a wiper value of 0x00 for both 7-bit and 8-bit devices.

The terminal B pin does not have a polarity relative to the terminal W or A pins. The terminal B pin can support both positive and negative current. The voltage on terminal B must be between V+ and V-.

3.12 Potentiometer Wiper (W) Terminal

The terminal W pin is connected to the internal potentiometer's terminal W (the Wiper). The wiper terminal is the adjustable terminal of the digital potentiometer. The terminal W pin does not have a polarity relative to terminal's A or B pins. The terminal W pin can support both positive and negative current. The voltage on terminal W must be between V+ and V-.

If the V+ voltage powers up before the V_L voltage, the Wiper is forced to midscale once the Analog POR voltage is crossed.

If the V+ voltage powers up after the V_L voltage is greater than the Digital POR voltage, the Wiper is forced to the value in the Wiper Register once the Analog POR voltage is crossed.

3.13 Potentiometer Terminal A

The terminal A pin is connected to the internal potentiometer's terminal A.

The potentiometer's terminal A is the fixed connection to the full scale wiper value of the digital potentiometer. This corresponds to a wiper value of 0xFF for 8-bit devices or 0x7F for 7-bit devices.

The terminal A pin does not have a polarity relative to the terminal W or B pins. The terminal A pin can support both positive and negative current. The voltage on terminal A must be between V+ and V-.

3.14 Analog Positive Voltage (V+)

Analog circuitry positive supply voltage. Must have a higher potential then the V- pin.

3.15 Exposed Pad (EP)

This pad is only on the bottom of the QFN packages. This pad is conductively connect to the device substrate. The EP pin must be connected to the Vsignal or left floating. This pad could be connected to a PCB heat sink to assist as a heat sink for the device.

4.0 FUNCTIONAL OVERVIEW

This data sheet covers a family of two volatile Digital Potentiometer devices that will be referred to as MCP41HVX1.

As the **Device Block Diagram** shows, there are six main functional blocks. These are:

- Operating Voltage Range
- POR/BOR Operation
- Memory Map
- Control Module
- Resistor Network
- Serial Interface (SPI)

The POR/BOR operation and the Memory Map are discussed in this section and the Resistor Network and SPI operation are described in their own sections. The **Device Commands** are discussed in **Section 7.0**.

4.1 Operating Voltage Range

The MCP41HVX1 devices have four voltage signals. These are:

- V+ Analog Power
- V_L Digital Power
- DGND Digital Ground
- V- Analog Ground

Figure 4-1 shows the two possible power-up sequences; analog power rails power-up first, or digital power rails power-up first. The device has been designed so that either power rail may power-up first. The device has a POR circuit for both Digital power circuitry and Analog power circuitry.

If the V+ voltage powers-up before the V_L voltage, the Wiper is forced to midscale once the Analog POR voltage is crossed.

If the V+ voltage powers-up after the V_L voltage is greater than the Digital POR voltage, the Wiper is forced to the value in the Wiper Register, once the Analog POR voltage is crossed.

Figure 4-2 shows the three cases of the digital power signals (V_L / DGND) with respect to the analog power signals (V+ / V-). The device implement level shifts between the digital and analog power systems, which allows the digital interface voltage to be anywhere in the V+ / V- voltage window.

4.2 POR/BOR Operation

The resister network's devices are powered by the analog power signals (V+ / V-), but the digital logic (including the wiper registers) is powered by the digital power signals (V_L / DGND). So, both the digital circuitry and analog circuitry have independent POR/BOR circuits.

The wiper position will be forced to the default state when the V+ voltage (relative to V-) is above the analog POR/BOR trip point. The wiper register will be in the default state when the V_L voltage (relative to DGND) is above the digital POR/BOR trip point.

The digital-signal-to-analog-signal voltage level shifters require a minimum voltage between the V_L and V-signals. This voltage requirement is below the operating supply voltage specifications. The wiper output may fluctuate while the V_L voltage is less than the level shifter operating voltage, since the analog values may not reflect the digital value. Output issues may be reduced by powering-up the digital supply voltages to their operating voltage, before powering the analog supply voltage.

4.2.1 POWER-ON RESET

Each power system has its own independent Poweron-Reset circuitry. This is done so that regardless of the power-up sequencing of the analog and digital power rails, the wiper output will be forced to a default value after minimum conditions are meet for either power supply.

Table 4-1 shows the interaction between the analog and digital PORs for the V+ and V_L voltages on the wiper pin state.

TABLE 4-1:WIPER PIN STATE BASED
ON POR CONDITIONS

	V+ Vo	oltage		
V_L Voltage	V+ <	V+ ≥	Comments	
	VAPOR	VAPOR		
$V_L < V_{DPOR}$	Unknown	Mid-Scale		
$V_L \ge V_{DPOR}$	Unknown	Wiper Register Value ⁽ 1)	Wiper Register can be updated	

Note 1: Default POR state of the Wiper Register value is the Mid-Scale value.

4.2.1.1 Digital Circuitry

The Digital Power-on Reset (DPOR) is the case where the device's V_L signal has power applied (referenced from DGND) and the voltage rises above the trip point. The Brown-out Reset (BOR) occurs when a device had power applied to it, and the voltage drops below the trip point.

The device's RAM retention voltage (V_{RAM}) is lower than the POR/BOR voltage trip point (V_{POR}/V_{BOR}). The maximum V_{POR}/V_{BOR} voltage is less then 1.8V.

When the device powers up, the device V_L will cross the V_{POR}/V_{BOR} voltage. Once the V_L voltage crosses the V_{POR}/V_{BOR} voltage, the following happens:

- Volatile wiper registers are loaded with the POR/ BOR value
- The TCON registers are loaded with the default values
- The device is capable of digital operation

Table 4-2 shows the default POR/BOR Wiper RegisterSetting Selection.

When $V_{POR}/V_{BOR} < V_{DD} < 2.7V$, the electrical performance may not meet the data sheet specifications. In this region, the device is capable of incrementing, decrementing, reading and writing to its volatile memory if the proper serial command is executed.

TABLE 4-2: DEFAULT POR/BOR WIPER REGISTER SETTING (DIGITAL)

Typical R _{AB} Value	Package Code	Default POR Wiper Register Setting	Device Resolution	Wiper Code
5.0 kO	502	Mid scalo	8-bit	7Fh
5.0 K12	-502	wild-scale	7-bit	3Fh
10.0 kg	102	Mid acolo	8-bit	7Fh
10.0 K22	-103	IVIIU-SCAIE	7-bit	3Fh
50.0 kO	502	Mid acolo	8-bit	7Fh
50.0 K22	-505	wild-scale	7-bit	3Fh
100.0 kg	104	Mid scalo	8-bit	7Fh
100.0 K22	-104	wild-scale	7-bit	3Fh

Note 1: Register setting independent of Analog power voltage.

4.2.1.2 Analog Circuitry

The Analog Power-on Reset (APOR) is the case where the device's V+ pin voltage has power applied (referenced from V-) and the V+ pin voltage rises above the trip point.

Once the V_L pin voltage exceeds the digital POR trip point voltage, the Wiper Register will control the wiper setting.

Table 4-3 shows the default POR/BOR Wiper Setting for when the V_L pin is not powered (< digital POR trip point).

TABLE 4-3: DEFAULT POR/BOR WIPER SETTING (ANALOG)

Typical R _{AB} Value	Package Code	Default POR Wiper Setting	Device Resolution
5 0 kO	502	Mid coolo	8-bit
5.0 K12	-502	IVIIU-SCAIE	7-bit
10.0 kg	102	Mid acala	8-bit
10.0 K12	-103	IVIIU-SCAIE	7-bit
50.0 kO	502	Mid acolo	8-bit
50.0 K12	-505	IVIIU-SCAIE	7-bit
100.0 kO			8-bit
100.0 K22	-104	wiu-scale	7-bit

Note 1: Wiper setting is dependent on the Wiper Register value if the V_L voltage is greater than the digital POR voltage.

FIGURE 4-3: DGND, V_L, V+, and V- Signal Waveform Examples.

4.2.2 BROWN-OUT RESET

Each power system has its own independent Brown-Out-Reset circuitry. This is done so that regardless of the power-down sequencing of the analog and digital power rails, the wiper output will be forced to a default value after the low voltage conditions are meet for either power supply.

Table 4-4 shows the interaction between the analog and digital BORs for the V+ and V_L voltages on the wiper pin state.

TABLE 4-4:WIPER PIN STATE BASED
ON BOR CONDITIONS

	V+ Vo	oltage		
V _L Voltage	V+ < V _{ABOR}	$V_{+} \ge V_{ABOR}$	Comments	
$V_L < V_{DBOR}$	Unknown	Mid-Scale		
$V_L \ge V_{DBOR}$	Unknown	Wiper Register Value ⁽ 1)	Wiper Register can be updated	

Note 1: Default POR state of the Wiper Register value is the Mid-Scale value.

4.2.2.1 Digital Circuitry

When the device's digital power supply powers down, the device V_L pin voltage will cross the digital V_{DPOR}/ V_{DBOR} voltage.

Once the V_L voltage decreases below the $V_{DPOR}/$ V_{DBOR} voltage, the following happens:

Serial Interface is disabled

If the V_{L} voltage decreases below the V_{RAM} voltage the following happens:

- · Volatile wiper registers may become corrupted
- TCON registers may become corrupted

Section 4.2.1, Power-on Reset describes what occurs as the voltage recovers above the V_{DPOR}/V_{DBOR} voltage.

Serial commands not completed due to a brown-out condition may cause the memory location to become corrupted.

The brown-out circuit establishes a minimum V_{DBOR} threshold for operation (V_{DBOR} < 1.8V). The digital BOR voltage (V_{DBOR}) is higher then the RAM retention voltage (V_{RAM}) so that as the device voltage crosses the digital BOR threshold, the value that is loaded into the volatile wiper register is not corrupted, due to RAM retention issues.

When $V_L < V_{DBOR}$, all communications are ignored and potentiometer terminals are forced to the analog BOR state.

Whenever V_L transitions from V_L < V_{DBOR} to V_L > V_{DBOR}, (a POR event) the Wiper's POR/BOR value is latched into the Wiper Register and the volatile TCON register is forced to the POR/BOR state.

When 1.8V \leq V_L, the device is capable of digital operation.

Table 4-5 shows the digital potentiometer's level of functionality across the entire V_L range, while Figure 4-4 illustrates the Power-up and Brown-out functionality.

4.2.2.2 Analog Circuitry

The Analog Brown-Out-Reset (ABOR) is the case where the device's V+ pin has power applied (referenced from V-) and the V+ pin voltage drops below the trip point. In this case, the resistor network terminals pins can become an unknown state.

MCP41HVX1

		-					
		Sorial	Potontiomotor	Wiper

	Invalid Range	Accepted	connected	Register determines Wiper Setting	Invalid		

TABLE 4-5:DEVICE FUNCTIONALITY AT EACH VL REGION

Note 1: For system voltages below the minimum operating voltage, it is recommended to use a voltage supervisor to hold the system in reset. This ensures that MCP41HVX1 commands are not attempted out of the operating range of the device.

2: Assumes that $V + > V_{APOR}$.

FIGURE 4-4: Power-up and Brown out - V+ / V- at Normal Operating Voltage.

4.3 Control Module

The control module controls the following functionality:

- Shutdown
- Wiper Latch

4.3.1 SHUTDOWN

The MCP41HVX1 has two methods to disconnect the terminal's pins (P0A, P0W, and P0B) from the resistor network. These are:

- Hardware Shutdown pin (SHDN)
- Terminal Control Register (TCON)

4.3.1.1 Hardware Shutdown Pin Operation

The SHDN pin has the same functionality as Microchip's family of standard voltage devices. When the SHDN pin is low, the POA terminal will disconnect (become open) while the POW terminal simultaneously connect to the POB terminal (see Figure 4-5).

Note: When the \overline{SHDN} pin is Active (V_{IL}), the state of the TCON register bits is overridden (ignored). When the state of the \overline{SHDN} pin returns to the Inactive state (V_{IH}), the TCON register bits return to controlling the terminal connection state. That is the value in the TCON register is not corrupted

The Hardware Shutdown pin mode does not corrupt the Volatile Wiper Register. So when Shutdown is exited, the device returns to the Wiper setting specified by the Volatile Wiper value. See **Section 5.7** for additional description details.

Note: When the SHDN pin is active, the Serial Interface is not disabled, and serial interface activity is executed.

FIGURE 4-5: Hardware Shutdown Resistor Network Configuration.

4.3.1.2 Terminal Control Register

The Terminal Control (TCON) register allows the device's terminal pins to be independently removed from the application circuit. These terminal control settings do not modify the wiper setting values. Also this has no effect on the serial interface and the memory/wipers are still under full user control.

The resistor network has four TCON bits associated with it. One bit for each terminal (A, W, and B) and one to have a software configuration that matches the configuration of the SHDN pin. These bits are named R0A, R0W, R0B, and R0HW. Register 4-1 describes the operation of the R0HW, R0A, R0B, and R0W bits.

Note: When the R0HW bit forces the resistor network into the hardware SHDN state, the state of the TCON register R0A, R0W, and R0B bits is overridden (ignored). When the state of the R0HW bit no longer forces the resistor network into the hardware SHDN state, the TCON register R0A, R0W, and R0B bits return to controlling the terminal connection state. That is, the R0HW bit does not corrupt the state of the R0A, R0W, and R0B bits.

Figure 4-6 shows how the SHDN pin signal and the R0HW bit signal interact to control the hardware shutdown of each resistor network (independently).

FIGURE 4-6: Interaction.

R0HW bit and SHDN pin

4.3.2 WIPER LATCH

The wiper latch pin is used to control when the new wiper value in the Wiper register is transferred to the wiper. This is useful for applications that need to synchronize the wiper updates. This may be for synchronization to an external event, such as zero crossing, or to synchronize the update of multiple digital potentiometers.

When the \overline{WLAT} pin is high, transfers from the Wiper register to the Wiper are inhibited. When the \overline{WLAT} pin is low, transfers may occur from the Wiper register to the Wiper. Figure 4-7 shows the interaction of the \overline{WLAT} pin and the loading of the Wiper.

If the external event crossing time is long, then the wiper could be updated the entire time that the WLAT signal is low. Once the \overline{WLAT} signal goes high, the transfer from the Wiper register is disabled. The Wiper register can continue to be updated. Only the \overline{CS} pin is used to enable/disable serial commands.

If the application does not require synchronized Wiper register updates, then the WLAT pin should be tied low.

- **Note 1:** This feature only inhibits the data transfer from the Wiper register to the Wiper.
 - 2: When the WLAT pin becomes active, data transferred to the Wiper will not be corrupted due to the Wiper Register Buffer getting loaded from an active SPI command.

4.3.3 DEVICE CURRENT MODES

There are two current modes for Volatile devices. These are:

- Serial Interface Inactive (Static Operation)
- · Serial Interface Active

For the SPI interface, Static Operation occurs when the \overline{CS} pin is at the V_{IH} voltage and the SCK pin is static (High or Low).

2: The WLAT pin should not be brought high during the falling edge of the 8th clock cycle of an Increment or Decrement command or the 16th clock cycle of a Write command.

FIGURE 4-7: WLAT Interaction with Wiper During Serial Communication - (SPI Mode 1, 1).

4.4 Memory Map

The device memory supports 16 locations that are 8bits wide (16x8 bits). This memory space contains only volatile locations (see Table 4-7).

4.4.1 VOLATILE MEMORY (RAM)

There are two volatile memory locations. These are:

- Volatile Wiper 0
- Terminal Control (TCON0) Register 0

The volatile memory starts functioning at the RAM retention voltage (V_{RAM}). The POR/BOR Wiper code is shown in Table 4-6.

Table 4-7 shows this memory map and which serial commands operate (and don't) on each of these locations.

Accessing an "invalid" address (for that device) or an invalid command for that address will cause an error condition (CMDERR) on the serial interface.

TABLE 4-6: WIPER POR STANDARD SETTINGS

Resistance	Typical B Value	Default POR Wiper	Wiper Code		
Code	RAB value	Setting	8-bit	7-bit	
-502	5.0 kΩ	Mid scale	7Fh	3Fh	
-103	10.0 kΩ	Mid scale	7Fh	3Fh	
-503	50.0 kΩ	Mid scale	7Fh	3Fh	
-104	100.0 kΩ	Mid scale	7Fh	3Fh	

4.4.1.1 Write to Invalid (Reserved) Addresses

Any write to a reserved address will be ignored and will generate an error condition. To exit the error condition, the user must take the \overline{CS} pin to the V_{IH} level and then back to the active state (V_{IL}).

TABLE 4-7:MEMORY MAP AND THE SUPPORTED COMMANDS

Address	Function	Allowed Commands	Disallowed Commands ⁽¹⁾	Memory Type
00h	Volatile Wiper 0	Read, Write, Increment, Decrement	_	RAM
01h - 03h	Reserved	none	Read, Write, Increment, Decrement	—
04h	Volatile TCON Register	Read, Write	Increment, Decrement	RAM
05h - 0Fh	Reserved	none	Read, Write, Increment, Decrement	—

Note 1: This command on this address will generate an error condition. To exit the error condition, the user must take the \overline{CS} pin to the V_{IH} level and then back to the active state (V_{IL}).

4.4.1.2 Terminal Control (TCON) Registers

The Terminal Control (TCON) Register contains 4 control bits for Wiper 0. Register 4-1 describes each bit of the TCON register.

The state of each resistor network terminal connection is individually controlled. That is, each terminal connection (A, B and W) can be individually connected/ disconnected from the resistor network. This allows the system to minimize the currents through the digital potentiometer. The value that is written to this register will appear on the resistor network terminals when the serial command has completed.

On a POR/BOR, these registers are loaded with FFh, for all terminals connected. The host controller needs to detect the POR/BOR event and then update the volatile TCON register values.

REGISTER 4-1: TCON0 BITS ⁽¹⁾ (CONTINUED)

R-1	R-1	R-1	R-1	R/W-1	R/W-1	R/W-1	R/W-1

-n = Value at POR	'1' = Bit is set	'0' = Bit is cleared	x = Bit is unknown

bit 7:4	D7-D4: Reserved. Forced to "1"			
bit 3	R0HW: Resistor 0 Hardware Configuration Control bit			
	 This bit forces Resistor 0 into the "shutdown" configuration of the Hardware pin 1 = Resistor 0 is NOT forced to the hardware pin "shutdown" configuration 0 = Resistor 0 is forced to the hardware pin "shutdown" configuration 			
bit 2	R0A: Resistor 0 Terminal A (P0A pin) Connect Control bit			
	 This bit connects/disconnects the Resistor 0 Terminal A to the Resistor 0 Network 1 = P0A pin is connected to the Resistor 0 Network 0 = P0A pin is disconnected from the Resistor 0 Network 			
bit 1	R0W: Resistor 0 Wiper (P0W pin) Connect Control bit			
	 This bit connects/disconnects the Resistor 0 Wiper to the Resistor 0 Network 1 = P0W pin is connected to the Resistor 0 Network 0 = P0W pin is disconnected from the Resistor 0 Network 			
bit 0	R0B: Resistor 0 Terminal B (P0B pin) Connect Control bit			
	 This bit connects/disconnects the Resistor 0 Terminal B to the Resistor 0 Network 1 = P0B pin is connected to the Resistor 0 Network 0 = P0B pin is disconnected from the Resistor 0 Network 			
Note 1:	These bits do not affect the wiper register values.			

2: The hardware SHDN pin (when active) overrides the state of these bits. When the SHDN pin returns to the inactive state, the TCON register will control the state of the terminals. The SHDN pin does not modify the state of the TCON bits.

5.0 **RESISTOR NETWORK**

The Resistor Network has either 7-bit or 8-bit resolution. Each Resistor Network allows zero scale to full-scale connections. Figure 5-1 shows a block diagram for the resistive network of a device. The Resistor network has up to three external connections. These are referred to as Terminal A, Terminal B, and the Wiper (or Terminal W).

The Resistor Network is made up of several parts. These include:

- Resistor Ladder Module
- Wiper
- Shutdown Control (Terminal Connections)

Terminal A and B as well as the Wiper W do not have a polarity. These terminals can support both positive and negative current.

5.1 Resistor Ladder Module

The R_{AB} resistor ladder is composed of the series of equal value Step resistors (R_S) and the Full-Scale (R_{FS}) and Zero-Scale (R_{ZS}) resistances:

$$R_{AB} = R_{ZS} + n * R_S + R_{FS}$$

Where "n" is determined by the resolution of the device. The R_{FS} and R_{ZS} resistances are discussed in Section 5.1.3.

There is a connection point (tap) between each R_S resistor. Each tap point is a connection point for an analog switch. The opposite side of the analog switch is connected to a common signal which is connected to the Terminal W (Wiper) pin (see Section 5.2).

Figure 5-1 shows a block diagram of the Resistor Network. The R_{AB} (and R_{S}) resistance has small variations over voltage and temperature.

The end points of the resistor ladder are connected to analog switches, which are connected to the device Terminal A and Terminal B pins. In the ideal case, these switches would have 0Ω of resistance, that is $R_{FS} = R_{ZS} = 0\Omega$. This will also be referred as the Simplified model.

For an 8-bit device, there are 255 resistors in a string between Terminal A and Terminal B. The wiper can be set to tap onto any of these 255 resistors, thus providing 256 possible settings (including Terminal A and Terminal B). A wiper setting of 00h connects Terminal W (wiper) to Terminal B (Zero Scale). A wiper setting of 7Fh is the Mid-scale setting. A wiper setting of FFh connects Terminal W (wiper) to Terminal A (Full Scale). Table 5-2 illustrates the full wiper setting map.

For a 7-bit device, there are 127 resistors in a string between Terminal A and Terminal B. The wiper can be set to tap onto any of these 127 resistors, thus providing 128 possible settings (including Terminal A and Terminal B). A wiper setting of 00h connects Terminal W (wiper) to Terminal B (Zero Scale). A wiper setting of 3Fh is the Mid-scale setting. A wiper setting of 7Fh connects the wiper to Terminal A (Full Scale). Table 5-2 illustrates the full wiper setting map.

5.1.1 R_{AB} CURRENT (I_{RAB})

The current through the R_{AB} resistor (A pin to B pin) is dependent on the voltage on the V_A and V_B pins and the R_{AB} resistance.

EQUATION 5-1: R_{AB}

 $R_{AB} = R_{ZS} + (n * R_S) + R_{FS} = \frac{|(V_A - V_B)|}{(I_{RAB})}$ $V_A \text{ is the voltage on the } V_A \text{ pin.}$ $V_B \text{ is the voltage on the } V_B \text{ pin.}$ $I_{RAB} \text{ is the current into the } V_{REF} \text{ pin.}$

5.1.2 STEP RESISTANCE (R_S)

Step resistance (R_S) is the resistance from one tap setting to the next. This value will be dependent on the R_{AB} value that has been selected (and the full scale and zero scale resistances). The R_S resistors are manufactured so that they should be very consistent with each other, and track each other's values as voltage and/or temperature change.

Equation 5-2 shows the simplified and detailed equations for calculating the R_S value. The simplified equation assumes R_{FS} = R_{ZS} = 0 Ω . Table 5-1 shows example step resistance calculations for each device, and the variation of the detailed model (R_{FS} \neq 0 Ω ; R_{ZS} \neq 0 Ω) from the simplified model (R_{FS} = R_{ZS} = 0 Ω). As the R_{AB} resistance option increases, the effects of the R_{ZS} and R_{FS} resistance decreases.

The total resistance of the device has minimal variation due to operating voltage (see device characterization graphs).

Equation 5-2 shows calculations for the step resistance.

TABLE 5-1: EXAMPLE STEP RESISTANCES (R_S) CALCULATIONS

Note 1: Delta % from Simplified Model R_S calculation value:

2: Assumes $R_{FS} = R_{ZS} = 0\Omega$.

3: Zero-Scale (R_{ZS}) and Full-Scale (R_{FS}) resistances are dependent on many operational characteristics of the device, including the V+ / V- voltage, the voltages on the A, B and W terminals, the wiper code selected, the R_{AB} resistance, and the temperature of the device.

5.1.3 R_{FS} AND R_{ZS} RESISTORS

The R_{FS} and R_{ZS} resistances are artifacts of the R_{AB} resistor network implementation. In the ideal model, the R_{FS} and R_{ZS} resistances would be 0 Ω . These resistors are included in the block diagram to help better model the actual device operation. Equation 5-3 shows how to estimate the R_S, R_{FS}, and R_{ZS} resistances, based on the measured voltages of V_{REF}, V_{FS}, and V_{ZS} and the measured current I_{VREF}.

EQUATION 5-3:	ESTIMATING R _S , R _{FS} ,
	AND R _{ZS}

R =	(V _A - V _{FS})		
INFS -	(I _{RAB})		
R =	(V _{ZS} - V _B)		
NZS -	(I _{RAB})		
R _S =	V _S (I _{RAB})		
Where: V _S =	$=\frac{(V_{FS} - V_{ZS})}{255}$	(8-bit device)	
V _S =	$=\frac{(V_{FS} - V_{ZS})}{127}$	(7-bit device)	
V _{FS} is the V _W voltage when the wiper code is at full-scale			

V_{ZS} is the V_W voltage when the wiper code is at zero-scale.

5.2 Wiper

The wiper terminal is connected to an analog switch mux, where one side of all the analog switches are connected together, the W terminal. The other side of each analog switch is connected to one of the taps of the R_{AB} resistor string (see Figure 5-1).

The value in the volatile wiper register selects which analog switch to close, connecting the W terminal to the selected node of the resistor ladder. The wiper register is 8-bits wide, and Table 5-2 shows the wiper value state for both 7-bit and 8-bit devices.

The wiper resistance (R_W) is the resistance of the selected analog switch in the analog mux. This resistance is dependent on many operational characteristics of the device, including the V+ / V- voltage, the voltages on the A, B and W terminals, the wiper code selected, the R_{AB} resistance, and the temperature of the device.

When the wiper value is at zero scale (00h), the Wiper is connected closest to the B terminal. When the wiper value is at full scale (FFh for 8-bit, 7Fh for 7-bit), the Wiper is connected closest to the A terminal.

A zero-scale wiper value connects the W terminal (wiper) to the B terminal (wiper = 00h). A full-scale wiper value connects the W terminal (wiper) to the A terminal (wiper = FFh (8-bit), or wiper = 7Fh (7-bit)). In these configurations, the only resistance between the terminal W and the other terminal (A or B) is that of the analog switches.

TABLE 5-2:	VOLATILE WIPER VALUE VS.
	WIPER POSITION

Wiper	Setting	Proportion	
7-bit	8-bit	Fropenties	
7Fh	FFh	Full Scale (W = A), Increment commands ignored	
7Eh - 40h	FEh - 80h	W = N	
3Fh	7Fh	W = N (Mid Scale)	
3Eh - 01h	7Eh - 01h	W = N	
00h	00h	Zero Scale (W = B) Decrement command ignored	

5.2.1 WIPER RESISTANCE (R_W)

Wiper resistance is significantly dependent on:

- The Resistor Network's Supply Voltage (V_{RN})
- The Resistor Network's Terminal (A, B, and W) Voltages
- Switch leakage (occurs at higher temperatures)
- I_W current

Figure 5-2 show the wiper resistance characterization data for all four RAB resistances and temperatures. Each RAB resistance determined the maximum wiper current based on worst case conditions R_{AB} = R_{AB} maximum and at full scale code, V_{BW} ~= V+ (but not exceeding V+). The V+ targets were 10V, 20V, and 36V. What this graph shows is that at higher RAB resistances (50 k Ω and 100 k Ω) and at the highest temperature (+125°C), the analog switch leakage causes a increase in the measured result of R_W . Where R_W is measured in a rheostat configuration with $R_W = (V_{BW} - V_{BW})$ V_{BA}) / I_{BW}.

FIGURE 5-2: R_W Resistance vs R_{AB} , Wiper Current (I_W), Temperature and Wiper Code.

Since there is minimal variation of the total device resistance (R_{AB}) over voltage, at a constant temperature (see device characterization graphs), the change in wiper resistance over voltage can have a significant impact on the R_{INL} and R_{DNL} errors.

5.2.2 POTENTIOMETER CONFIGURATION

In a potentiometer configuration, the wiper resistance variation does not effect the output voltage seen on the W pin and therefore is not a significant source of error.

5.2.3 RHEOSTAT CONFIGURATION

In a rheostat configuration, the wiper resistance variation creates nonlinearity in the R_{BW} (or R_{AW}) value. The lower the nominal resistance (R_{AB}), the greater the possible relative error. Also a change in voltage needs to be taken into account. For the 5.0 k Ω device the maximum wiper resistance at 5.5V is approximately 6% of the total resistance, while at 2.7V it is approximately 6.5% of the total resistance.

5.2.4 LEVEL SHIFTERS (DIGITAL TO ANALOG)

Since the digital logic may operate anywhere within the analog power range, level shifters are present so that the digital signals control the analog circuitry. This level shifter logic is relative to the V- and V_L voltages. A delta voltage of 2.7V between V_L and V- is required for the serial interface to operate at the maximum specified frequency.
5.3 Terminal Currents

The terminal currents are limited by several factors, including the R_{AB} resistance (R_S resistance). The maximum current occurs when the wiper is at either the zero-scale (I_{BW}) or full-scale (I_{AW}) code. In this case, the current is only going through the analog switches (see I_T specification in **Electrical Characteristics**). When the current passes through at least one R_S resistive element, then the maximum terminal current (I_T) has a different limit. The current through the R_{AB} resistor is limited by the R_{AB} resistance. The worst case (max current) occurs when the resistance is at the minimum R_{AB} value.

Higher current capabilities allow a greater delta voltage between the desired terminals for a given resistance. This also allows a more usable range of wiper code values, without violating the maximum terminal current specification. Table 5-3 shows resistance and current calculations based on the R_{AB} resistance (R_S resistance) for a system that supports ± 18V (Δ 36V). In Rheostat configuration, the minimum wiper-code value is shown (for V_{BW} = 36V). As the V_{BW} voltage decreases, the minimum wiper-code value also decreases. Using a wiper code less then this value will cause the maximum terminal current (I_T) specification to be violated.

Note: For high terminal-current applications, it is recommended that proper PCB layout techniques be used to address the thermal implications of this high current. The QFN package has better thermal properties than the TSSOP package.

			. ,						10	23	/

TABLE 5-3:TERMINAL (WIPER) CURRENT AND WIPER SETTINGS ($R_W = R_{FS} = R_{ZS} = 0\Omega$)

Note 1: I_{BW} or I_{AW} currents can be much higher then this depending on voltage differential between Terminal B and Terminal W or Terminal A and Terminal W.

2: Any R_{BW} resistance greater then this limits the current.

3: If V_{BW} = 36V, then the wiper code value must be greater than or equal to Min 'N'. Wiper codes less than Min 'N' will cause the wiper current (I_W) to exceed the specification. Wiper codes greater than Min 'N' will cause the wiper current to be less then the maximum. The Min 'N' number has been rounded up from the calculated number to ensure that the wiper current does not exceed the maximum specification.

MCP41HVX1

Figure 5-3 through Figure 5-6 show a graph of the calculated currents (minimum, typical, and maximum) for each resistor option. These graphs are based on 25 mA (5 k Ω), 12.5 mA (10 k Ω), and 6.5 mA (50 k Ω and 100 k Ω) specifications.

To ensure no damage to the resistor network (including long-term reliability) the maximum terminal current must not be exceeded. This means that the application must assume that the R_{AB} resistance is the minimum R_{AB} value (R_{AB(MIN)}, see blue lines in graphs).

Looking at the 50 k Ω device, the maximum terminal current is 6.5 mA. That means that any wiper code value greater than 36 ensures that the terminal current is less than 6.5 mA. This is \sim 14% of the full scale value. If the application could change to the 100 k Ω device, which has the same maximum terminal current specification, any wiper-code value greater than 18 ensures that the terminal current is less than 6.5 mA. This is ~7% of the full-scale value. Supporting higher terminal current allows a greater wiper code range for a given V_{BW} voltage.

FIGURE 5-3: Maximum I_{BW} vs Wiper Code - $5 k\Omega$.

Code - 10 kΩ.

Maximum I_{BW} vs Wiper

FIGURE 5-5: Maximum I_{BW} vs Wiper Code - 50 k Ω .

FIGURE 5-6: Maximum I_{BW} vs Wiper Code - 100 k Ω .

Figure 5-7 shows a graph of the maximum V_{BW} voltage vs wiper code (for 5 k Ω and 10 k Ω devices). To ensure that no damage is done to the resistor network, the RAB(MIN) resistance (blue line) should be used to determine V_{BW} voltages for the circuit. Devices where the R_{AB} resistance is greater than the $R_{AB(MIN)}$ resistance will naturally support a higher voltage limit.

FIGURE 5-7: Maximum V_{BW} vs Wiper Code (5 $k\Omega$ and 10 $k\Omega$ devices).

Table 5-4 shows the maximum V_{BW} voltage that can be applied across the Terminal B to Terminal W pins for a given wiper code value (for the 5 k Ω and 10 k Ω devices). These calculations assume the ideal model (R_W = R_{FS} = R_{ZS} = 0Ω) and show the calculations based on $R_{S(MIN)}$ and $R_{S(MAX)}$. Table 5-5 shows the same calculations for the 50 k Ω devices, and Table 5-6 shows the calculations for the 100 k Ω devices. These tables are supplied as a quick reference.

2: This wiper code and greater will limit the I_{BW} current to less than the maximum supported terminal current (I_T).

5.4 Variable Resistor (Rheostat)

A variable resistor is created using terminal W and either terminal A or Terminal B. Since the wiper-code value of 0 connects the wiper to the terminal B, the R_{BW} resistance increases with increasing wiper code value. Conversely, the R_{AW} resistance will decrease with increasing wiper code value. Figure 5-8 shows the connections from a potentiometer to create a rheostat configuration.

Rheostat Configuration.

Equation 5-4 shows the R_{BW} and R_{AW} calculations. The R_{BW} calculation is for the resistance between the wiper and terminal B. The R_{AW} calculation is for the resistance between the wiper and terminal A.

EQUATION 5-4: R_{BW} AND R_{AW} CALCULATION

5.5 Analog Circuitry Power Requirements

This device has two power supplies. One is for the digital interface (VL and DGND) and the other is for the high voltage analog circuitry (V+ and V-). The maximum delta voltage between V+ and V- is 36V. The digital power signals must be between V+ and V-.

If the digital ground (DGND) pin is at half the potential of V+ (relative to V-), then the terminal pins potentials can be \pm (V+/2) relative to DGND.

Figure 5-9 shows the relationship of the four power signals. This shows that the V+ / V- signals do not need to be symmetric around the DGND signal.

To ensure that the wiper register has been properly loaded with the POR/BOR value, the V_L voltage must be at the minimum specified operating voltage (referenced to DGND).

5.6 Resistor Characteristics

5.6.1 V+ / V- LOW VOLTAGE OPERATION

The resistor network is specified from 20V to 36V. At voltages below 20V, the resistor network will function, but the operational characteristics may be outside the specified limits. Please refer to **Section 2.0** "**Typical Performance Curves**" for additional information.

5.6.2 RESISTOR TEMPCO

Biasing the ends (Terminal A and Terminal B) near mid-supply ((V+ - |V-|) / 2) will give the worst switch resistance tempco.

5.7 Shutdown Control

Shutdown is used to minimize the device's current consumption. The MCP41HVX1 has two methods to achieve this:

- Hardware Shutdown Pin (SHDN)
- Terminal Control Register (TCON)

The Hardware Shutdown pin is backwards compatible with the MCP42X1 devices.

5.7.1 HARDWARE SHUTDOWN PIN (SHDN)

The \overline{SHDN} pin is available on the potentiometer devices. When the \overline{SHDN} pin is forced active (V_{IL}):

- The P0A terminal is disconnected
- The POW terminal is connected to the POB terminal (see Figure 4-5)
- The Serial Interface is NOT disabled, and all Serial Interface activity is executed

The Hardware Shutdown pin mode does NOT corrupt the values in the Volatile Wiper Registers nor the TCON register. When the Shutdown mode is exited (SHDN pin is inactive (V_{IH})):

- The device returns to the Wiper setting specified by the Volatile Wiper value
- The TCON register bits return to controlling the terminal connection state

FIGURE 5-10: Hardware Shutdown Resistor Network Configuration.

5.7.2 TERMINAL CONTROL REGISTER (TCON)

The Terminal Control (TCON) register is a volatile register used to configure the connection of each resistor network terminal pin (A, B and W) to the Resistor Network. This register is shown in Register 4-1.

The R0HW bit forces the selected resistor network into the same state as the \overline{SHDN} pin. Alternate low-power configurations may be achieved with the R0A, R0W and R0B bits.

When the R0HW bit is "0":

- The P0A terminal is disconnected
- The P0W terminal is simultaneously connect to the P0B terminal (see Figure 5-11)

Note: When the R0HW bit forces the resistor network into the hardware SHDN state, the state of the TCON0 register's R0A, R0W and R0B bits is overridden (ignored). When the state of the R0HW bit no longer forces the resistor network into the hardware SHDN state, the TCON0 register's R0A, R0W and R0B bits return to controlling the terminal connection state. In other words, the R0HW bit does not corrupt the state of the R0A, R0W and R0B bits.

The R0HW bit does NOT corrupt the values in the Volatile Wiper registers nor the TCON register. When the Shutdown mode is exited (R0HW bit = 1):

- The device returns to the Wiper setting specified by the Volatile Wiper value
- The TCON register bits return to controlling the terminal connection state

FIGURE 5-11: Resistor Network Shutdown State (ROHW = 0).

5.7.3 INTERACTION OF SHDN PIN AND TCON REGISTER

Figure 4-6 shows how the SHDN pin signal and the R0HW bit signal interact to control the hardware shutdown of the resistor network.

FIGURE 5-12: R0HW bit and SHDN pin Interaction.

6.0 SERIAL INTERFACE (SPI)

The MCP41HVX1 devices support the SPI serial protocol. This SPI operates in the Slave mode (does not generate the serial clock). The device's SPI command format operates on multiples of 8-bits.

The SPI interface uses up to four pins. These are:

- $\overline{\text{CS}}$ Chip Select
- SCK Serial Clock
- SDI Serial Data In
- SDO Serial Data Out

A typical SPI interface is shown in Figure 6-1. In the SPI interface, the Master's Output pin is connected to the Slave's Input pin and the Master's Input pin is connected to the Slave's Output pin.

The MCP41HVX1 SPI's module supports two (of the four) standard SPI modes. These are Mode 0,0 and 1,1. The SPI mode is determined by the state of the SCK pin (V_{IH} or V_{IL}) on the when the CS pin transitions from inactive (V_{IH}) to active (V_{IL}).

Note: Some Host Controller SPI modules only operate with 16-bit transfers. For these Host Controllers, only the Read and Write Commands may be used, or the Continuous Increment or Decrement Commands that are an even multiple of Increment or Decrement commands.

Host			MCP41HVX1
Controller	SDO	(Master Out - Slave In (MOSI))	SDI
	SDI	(Master In - Slave Out (MISO))	SDO
	SCK		SCK
	I/O		
	I/O		WLAT
	I/O		SHDN

FIGURE 6-1: Typical SPI Interface Block Diagram.

6.1 SDI, SDO, SCK, and CS Operation

The operation of the four SPI interface pins are discussed in this section. These pins are:

- Serial Data In (SDI)
- Serial Data Out (SDO)
- Serial Clock (SCK)
- The Chip Select Signal (CS)

The serial interface works on either 8-bit or 16-bit boundaries depending on the selected command. The Chip Select (\overline{CS}) pin frames the SPI commands.

6.1.1 SERIAL DATA IN (SDI)

The Serial Data In (SDI) signal is the data signal into the device. The value on this pin is latched on the rising edge of the SCK signal.

6.1.2 SERIAL DATA OUT (SDO)

The Serial Data Out (SDO) signal is the data signal out of the device. The value on this pin is driven on the falling edge of the SCK signal.

Once the \overline{CS} pin is forced to the active level (V_{IL}), the SDO pin will be driven. The state of the SDO pin is determined by the serial bit's position in the command, the command selected, and if there is a command error state (CMDERR).

6.1.3 SERIAL CLOCK (SCK)

The Serial Clock (SCK) signal is the clock signal of the SPI module. The frequency of the SCK pin determines the SPI frequency of operation.

The SPI interface is specified to operate up to 10 MHz. The actual clock rate depends on the configuration of the system and the serial command used. Table 6-1 shows the SCK frequency.

	Со	nmand		
V _L Voltage	Read	Write, Increment, Decrement	Comment	
2.7V	10 MHz	10 MHz		
1.8V	1 MHz	1 MHz	DGND = V- + 0.9V	
2.0V	1 MHz	1 MHz	DGND = V-	

TABLE 6-1:SCK FREQUENCY

6.1.4 THE CHIP SELECT SIGNAL (CS)

The Chip Select (\overline{CS}) signal is used to select the device and frame a command sequence. To start a command, or sequence of commands, the \overline{CS} signal must transition from the inactive state (V_{IH}) to an active state (V_{IL}).

After the \overline{CS} signal has gone active, the SDO pin is driven and the clock bit counter is reset.

Note:	There is a required delay after the $\overline{\text{CS}}$ pin
	goes active to the 1st edge of the SCK pin.

If an error condition occurs for an SPI command, then the command byte's Command Error (CMDERR) bit (on the SDO pin) will be driven low (V_{IL}). To exit the error condition, the user must take the CS pin to the V_{IH} level.

When the \overline{CS} pin returns to the inactive state (V_{IH}), the SPI module resets (including the Address Pointer). While the \overline{CS} pin is in the inactive state (V_{IH}), the serial interface is ignored. This allows the host controller to interface to other SPI devices using the same SDI, SDO and SCK signals.

6.1.5 LOW VOLTAGE SUPPORT

The Serial Interface is designed to also support 1.8V operation (at reduced specifications - frequency, thresholds, etc.). This allows the MCP41HVX1 device to interface to low-voltage host controllers.

At 1.8V V_L operation, the DGND signal must be 0.9V or greater above the V- signal. If V_L is 2.0V or greater, than the DGND signal can be tied to the V- signal (see Table 6-1).

6.1.6 SPLIT RAIL SUPPORT

The Serial Interface is designed to support split rail systems. In a split rail system, the microcontroller can operate at a lower voltage than the MCP41HXX1 device. This is achieved with the V_{IH} specification.

For V_L \ge 2.7V, the minimum V_{IH} = 0.45 * V_L. So if the microcontroller V_{OH} at 1.8V is 0.8 * V_{DD}, then V_L can be a maximum of 3.2V (see Equation 6-1).

See **Section 8.1** for additional discussion on split rail support.

EQUATION 6-1: CALCULATING MAX VL FOR MICROCONTROLLER AT 1.8V

If V_{OH} = 0.8 * V_{DD} = 0.8 * 1.8V = 1.44V

Then: V_{IH(MIN)} = 1.44V

With $V_{IH} = 0.45 * V_I$

Then: V_I = 1.44V / 0.45 = 3.2V

6.2 The SPI Modes

The SPI module supports two (of the four) standard SPI modes. These are Mode 0,0 and 1,1. The mode is determined by the state of the SDI pin on the rising edge of the first clock bit (of the 8-bit byte).

6.2.1 MODE 0,0

In **Mode 0,0**: SCK Idle state = low (V_{IL}), data is clocked in on the SDI pin on the rising edge of SCK and clocked out on the SDO pin on the falling edge of SCK.

6.2.2 MODE 1,1

In **Mode 1,1**: SCK Idle state = high (V_{IH}), data is clocked in on the SDI pin on the rising edge of SCK and clocked out on the SDO pin on the falling edge of SCK.

6.3 SPI Waveforms

Figure 6-2 through Figure 6-5 show the different SPI command waveforms. Figure 6-2 and Figure 6-3 are read and write commands. Figure 6-4 and Figure 6-5 are Increment and Decrement commands.

6.4 Daisy Chaining

This SPI Interface does **NOT** support daisy chaining.

FIGURE 6-2: 16-Bit Commands (Write, Read) – SPI Waveform (Mode 1,1).

FIGURE 6-4: 8-Bit Commands (Increment, Decrement) – SPI Waveform with PIC MCU (Mode 1, 1).

FIGURE 6-5: 8-Bit Commands (Increment, Decrement) – SPI Waveform with PIC MCU (Mode 0,0).

7.0 DEVICE COMMANDS

The MCP41HVX1's SPI command format supports 16 memory address locations and four commands. These commands are shown in Table 7-1.

Commands may be sent when the \overline{CS} pin is driven to V_{IL}. The 8-bit commands (**Increment Wiper** and **Decrement Wiper** commands) contain a command byte, see Figure 7-1, while 16-bit commands (**Read Data** and **Write Data** commands) contain a command byte and a data byte. The command byte contains two data bits, see Figure 7-1.

Table 7-2 shows the supported commands for each memory location and the corresponding values on the SDI and SDO pins.

C1:C0 Bit States	Command Name	# of Bits
11	Read Data	16-Bits
00	Write Data	16-Bits
01	Increment Wiper	8-Bits
10	Decrement Wiper	8-Bits

TABLE 7-1: COMMANDS

7.1 Command Format

All commands have a **Command Byte**, which specifies the register address and the command. Commands which require data (write and read commands), also have the **Data Byte**.

7.1.1 COMMAND BYTE

The command byte has three fields, the address, the command, and two data bits, see Figure 7-1. Currently only one of the data bits is defined (D8). This is for the Write command.

The device memory is accessed when the master sends a proper command byte to select the desired operation. The memory location to be accessed is contained in the command byte's AD3:AD0 bits. The action desired is contained in the command byte's C1:C0 bits, see Table 7-1. C1:C0 determines if the desired memory location will be read, written, incremented (wiper setting +1) or decremented (wiper setting -1). The Increment and Decrement commands are only valid on the volatile wiper registers.

As the command byte is being loaded into the device (on the SDI pin), the device's SDO pin is driving. The SDO pin will output high bits for the first six bits of that command. On the 7th bit, the SDO pin will output the CMDERR bit state (see Section 7.1.1.1 "Error Condition"). The 8th bit state depends on the command selected.

	Address	Command	Data	SPI String (Binary)			
Value	Function	Command	(10-bits) ⁽ 1 ⁾	MOSI (SDI pin)	MISO (SDO pin) ⁽ 2 ⁾		
00h	Volatile Wiper 0	Write Data	nn nnnn nnnn	0000 00nn nnnn nnnn	1111 1111 1111 1111		
		Read Data	nn nnnn nnnn	0000 11nn nnnn nnnn	1111 111n nnnn nnnn		
		Increment Wiper	—	0000 0100	1111 1111		
		Decrement Wiper	—	0000 1000	1111 1111		
01h - 03h ⁽ <mark>4</mark>)	Reserved	—	—	—	—		
04h ⁽ 3)	Volatile	Write Data	nn nnnn nnnn	0100 00nn nnnn nnnn	1111 1111 1111 1111		
	TCON Register	Read Data	nn nnnn nnnn	0100 11nn nnnn nnnn	1111 111n nnnn nnnn		
05h - 0Fh ⁽ <mark>4</mark>)	Reserved	—		—	—		

TABLE 7-2:MEMORY MAP AND THE SUPPORTED COMMANDS

Note 1: The data memory is 8-bits wide, so the two MSbs (D9:D8) are ignored by the device.

2: All these address/command combinations are valid, so the CMDERR bit is set. Any other address/ command combination is a command error state and the CMDERR bit will be clear.

3: Increment or Decrement commands are invalid for these addresses.

4: Reserved addresses: Any command is invalid for these addresses.

7.1.1.1 Error Condition

The CMDERR bit indicates if the four address bits received (AD3:AD0) and the two command bits received (C1:C0) are a valid combination. The CMDERR bit is high if the combination is valid and low if the combination is invalid (see Table 7-3).

The command error bit will also be low if a write to a Reserved Address has been specified. SPI commands that do not have a multiple of eight clocks are ignored.

Once an error condition has occurred, any following commands are ignored. All following SDO bits will be low until the CMDERR condition is cleared by forcing the $\overline{\text{CS}}$ pin to the inactive state (V_{IH}).

TABLE 7-3: COMMAND ERROR BIT

CMDERR Bit States	Description
1	"Valid" Command/Address combination
0	"Invalid" Command/Address combination

Aborting a Transmission

All SPI transmissions must have the correct number of SCK pulses to be executed. The command is not executed until the complete number of clocks have been received. Some commands also require the \overline{CS} pin to be forced inactive (V_{IH}). If the \overline{CS} pin is forced to the inactive state (V_{IH}), the serial interface is reset. Partial commands are not executed.

SPI is more susceptible to noise than other bus protocols. The most likely case is that this noise corrupts the value of the data being clocked into the MCP41HVX1 or the SCK pin is injected with extra clock pulses. This may cause data to be corrupted in the device, or a command error to occur, since the address and command bits were not a valid combination. The extra SCK pulse will also cause the SPI data (SDI) and clock (SCK) to be out of sync. Forcing the CS pin to the inactive state (V_{IH}) resets the serial interface. The SPI interface will ignore activity on the SDI and SCK pins until the \overline{CS} pin transition to the active state is detected (V_{IH} to V_{IL}).

Note 1:	When data is not being received by the $\frac{MCP41HVX1}{CS}$ pin be forced to the inactive level (V _{IL})
2:	It is also recommended that long continuous command strings should be broken down into single commands or shorter continuous command strings. This reduces the probability of noise on the SCK pin corrupting the desired SPI commands.

7.1.2 DATA BYTE

Only the Read command and the Write command use the data byte, see Figure 7-1. These commands concatenate the 8 bits of the data byte with the one data bit (D8) contained in the command byte to form 9bits of data (D8:D0). The command byte format supports up to 9-bits of data, but the MCP41HVX1 only uses the lower 8-bits. That means that the Full Scale code of the 8-bit resistor network is FFh. When at Full Scale, the wiper connects to Terminal A. The D8 bit is maintained for code compatibility with the MCP41XX, MCP42XX, and MCP43XX devices.

The D9 bit is currently unused, and corresponds to the position on the SDO data of the CMDERR bit.

7.1.3 CONTINUOUS COMMANDS

The device supports the ability to execute commands continuously while the \overline{CS} pin is in the active state (V_{IL}). Any sequence of valid commands may be received.

The following example is a valid sequence of events:

- 1. $\overline{\text{CS}}$ pin driven active (V_{IL}).
- 2. Read Command.
- 3. Increment Command (Wiper 0).
- 4. Increment Command (Wiper 0).
- 5. Decrement Command (Wiper 0).
- 6. Write Command.
- 7. Read Command.
- 8. $\overline{\text{CS}}$ pin driven inactive (V_{IH}).

Note 1: It is recommended that while the \overline{CS} pin is active, only one type of command should be issued. When changing commands, it is recommended to take the \overline{CS} pin inactive, then force it back to the active state.

2: It is also recommended that long command strings should be broken down into shorter command strings. This reduces the probability of noise on the SCK pin corrupting the desired SPI command string.

7.2 Write Data

The Write command is a 16-bit command. The format of the command is shown in Figure 7-2.

A Write command to a volatile memory location changes that location after a properly formatted Write command (16-clock) has been received.

7.2.1 SINGLE WRITE TO VOLATILE MEMORY

The write operation requires that the \overline{CS} pin be in the active state (V_{IL}). Typically, the \overline{CS} pin will be in the inactive state (V_{IL}) and is driven to the active state (V_{IL}). The 16-bit Write command (command byte and data byte) is then clocked (SCK pin) in on the SDI pin. Once all 16 bits have been received, the specified volatile address is updated. A write will not occur if the write command isn't exactly 16 clocks pulses.

Figure 6-2 and Figure 6-3 show possible waveforms for a single write.

7.2.2 CONTINUOUS WRITES TO VOLATILE MEMORY

Continuous writes are possible only when writing to the volatile memory registers (address 00h and 04h).

Figure 7-3 shows the sequence for three continuous writes. The writes do not need to be to the same volatile memory address.

7.3 Read Data

The Read command is a 16-bit command. The format of the command is shown in Figure 7-4.

The first six bits of the Read command determine the address and the command. The 7th clock will output the CMDERR bit on the SDO pin. The 8th clock will be fixed at 1, and the remaining 8-clocks the device will transmit the eight data bits (D7:D0) of the specified address (AD3:AD0).

Figure 7-4 shows the SDI and SDO information for a Read command.

7.3.1 SINGLE READ

The read operation requires that the \overline{CS} pin be in the active state (V_{IL}). Typically, the \overline{CS} pin will be in the inactive state (V_{IL}). Typically, the \overline{CS} pin will be in the inactive state (V_{IL}). The 16-bit Read command (command byte and data byte) is then clocked (SCK pin) in on the SDI pin. The SDO pin starts driving data on the 7th bit (CMDERR bit) and the addressed data comes out on the 8th through 16th clocks. Figure 6-2 through Figure 6-3 show possible waveforms for a single read.

FIGURE 7-4:

Read Command – SDI and SDO States.

7.3.2 CONTINUOUS READS

Continuous reads allow the device's memory to be read quickly. Continuous reads are possible to all memory locations.

Figure 7-5 shows the sequence for three continuous reads. The reads do not need to be to the same memory address.

7.4 Increment Wiper

The Increment command is an 8-bit command. The Increment command can only be issued to specific volatile memory locations (the Wiper register). The format of the command is shown in Figure 7-6.

An Increment command to the volatile memory location changes that location after a properly formatted command (8-clocks) have been received.

Increment commands provide a quick and easy method to modify the value of the volatile wiper location by +1 with minimal overhead.

at this bit location (*), then all following SDO bits will be driven low until the \overline{CS} pin is driven inactive (V_{IH}).

FIGURE 7-6: Increment Command – SDI and SDO States.

Note:	Table 7-2 shows the valid addresses for
	the Increment Wiper command. Other
	addresses are invalid.

7.4.1 SINGLE INCREMENT

Typically, the \overline{CS} pin starts at the inactive state (V_{IH}), but may already be in the active state due to the completion of another command.

Figure 6-4 through Figure 6-5 show possible waveforms for a single increment. The increment operation requires that the \overline{CS} pin be in the active state (V_{IL}). Typically, the \overline{CS} pin will be in the inactive state (V_{IH}) and is driven to the active state (V_{IL}). The 8-bit Increment command (command byte) is then clocked in on the SDI pin by the SCK pins. The SDO pin drives the CMDERR bit on the 7th clock.

The wiper value will increment up to FFh on 8-bit devices and 7Fh on 7-bit devices. After the wiper value has reached full scale (8-bit = FFh, 7-bit = 7Fh), the wiper value will not be incremented further. See Table 7-4 for additional information on the Increment command versus the current volatile wiper value.

The increment operations only require the Increment command byte while the \overline{CS} pin is active (V_{IL}) for a single increment.

After the wiper is incremented to the desired position, the \overline{CS} pin should be forced to V_{IH} to ensure that unexpected transitions on the SCK pin do not cause the wiper setting to change. Driving the \overline{CS} pin to V_{IH} should occur as soon as possible (within device specifications) after the last desired increment occurs.

TABLE 7-4 :	INCREMENT OPERATION VS.
	VOLATILE WIPER VALUE

Current Wiper Setting		Wiper (W)	Increment
7-bit Pot	8-bit Pot	Properties	Operates?
7Fh	FFh	Full Scale (W = A)	No
7Eh	FEh	W = N	
40h	80h		
3Fh	7Fh	W = N (Mid-scale)	Yes
3Eh	7Eh	W = N	
01h	01h		
00h	00h	Zero Scale (W = B)	Yes

7.4.2 CONTINUOUS INCREMENTS

Continuous increments are possible only when writing to the volatile Wiper registers (address 00h).

Figure 7-7 shows a continuous increment sequence.

When executing a continuous Increment command, the selected wiper will be altered from n to n+1 for each Increment command received. The wiper value will increment up to FFh on 8-bit devices and 7Fh on 7-bit devices. After the wiper value has reached full scale (8bit = FFh, 7-bit = 7Fh), the wiper value will not be incremented further.

Increment commands can be sent repeatedly without raising $\overline{\text{CS}}$ until a desired condition is met.

When executing a continuous command string, the Increment command can be followed by any other valid command.

The wiper terminal will move after the command has been received (8th clock).

After the wiper is incremented to the desired position, the \overline{CS} pin should be forced to V_{IH} to ensure that unexpected transitions (on the SCK pin <u>do</u> not cause the wiper setting to change). Driving the \overline{CS} pin to V_{IH} should occur as soon as possible (within device specifications) after the last desired increment occurs.

	_		COI	MMA	ND	BY.	TE	_	COMMAND BYTE					COMMAND BYTE					_							
	(INCR COMMAND (n+1)) (INCR COMMAND (n+2)) (INCR COMMAND (n+3))																									
SDI	A D 3	A D 2	A D 1	A D 0	0	1	X	Х	A D 3	A D 2	A D 1	A D 0	0	1	Х	Х	A D 3	A D 2	A D 1	A D 0	0	1	Х	Х		
	1	1	1	1	1	1	1*	1	1	1	1	1	1	1	1*	1	1	1	1	1	1	1	1*	1	Note 1,	2
SDO	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	Note 3,	4
000	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	Note 3,	4
	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	Note 3,	4
	 Note 1: Only functions when writing the volatile wiper register (AD3:AD0 = 0h). 2: Valid Address/Command combination. 3: Invalid Address/Command combination. 																									
	 3: Invalid Address/Command combination. 4: If an Error Condition occurs (CMDERR = L), all following SDO bits will be low until the CMDERR condition is cleared (the CS pin is forced to the inactive state). 																									

7.5 Decrement Wiper

The Decrement command is an 8-bit command. The Decrement command can only be issued to volatile Wiper locations. The format of the command is shown in Figure 7-8.

A Decrement command to the volatile Wiper location changes that location after a properly formatted command (8 clocks) have been received.

Decrement commands provide a quick and easy method to modify the value of the volatile wiper location by -1 with minimal overhead.

4: If a Command Error (CMDERR) occurs at this bit location (*), then all following SDO bits will be driven low until the CS pin is driven inactive (V_{IH}).

FIGURE 7-8: Decrement Command – SDI and SDO States.

Note:	Table 7-2 shows the valid addresses for							
	the Decrement Wiper command. Other							
	addresses are invalid.							

7.5.1 SINGLE DECREMENT

Typically, the \overline{CS} pin starts at the inactive state (V_{IH}), but may already be in the active state due to the completion of another command.

Figure 6-4 through Figure 6-5 show possible waveforms for a single decrement. The decrement operation requires that the \overline{CS} pin be in the active state (V_{IL}). Typically, the \overline{CS} pin will be in the inactive state (V_{IL}) and is driven to the active state (V_{IL}). Then the 8-bit Decrement command (command byte) is clocked in on the SDI pin by the SCK pin. The SDO pin drives the CMDERR bit on the 7th clock.

The wiper value will decrement from the wiper's full scale value (FFh on 8-bit devices and 7Fh on 7-bit devices). If the wiper register has a zero scale value (00h), then the wiper value will not decrement. See Table 7-5 for additional information on the Decrement command vs. the current volatile wiper value.

The Decrement commands only require the Decrement command byte, while the \overline{CS} pin is active (V_{IL}or V_{IHH}) for a single decrement.

After the wiper is decremented to the desired position, the \overline{CS} pin should be forced to V_{IH} to ensure that unexpected transitions on the SCK pin do not cause the wiper setting to change. Driving the \overline{CS} pin to V_{IH} should occur as soon as possible (within device specifications) after the last desired decrement occurs.

TABLE 7-5:	DECREMENT OPERATION VS.
	VOLATILE WIPER VALUE

Current Wiper Setting		Wiper (W)	Decrement
7-bit Pot	8-bit Pot	Properties	Operates?
7Fh	FFh	Full Scale (W = A)	Yes
7Eh	FEh	W = N	
40h	80h		
3Fh	7Fh	W = N (Mid-scale)	Yes
3Eh	7Eh	W = N	
01h	01h		
00h	00h	Zero Scale (W = B)	No

7.5.2 CONTINUOUS DECREMENTS

Continuous decrements are possible only when writing to the volatile Wiper register (address 00h).

Figure 7-9 shows a continuous decrement sequence.

When executing continuous Decrement commands, the selected wiper will be altered from n to n-1 for each Decrement command received. The wiper value will decrement from the wiper's full scale value (FFh on 8-bit devices and 7Fh on 7-bit devices). If the Wiper register has a zero scale value (00h), then the wiper value will not decrement. See Table 7-5 for additional information on the Decrement command vs. the current volatile wiper value.

Decrement commands can be sent repeatedly without raising \overline{CS} until a desired condition is met.

When executing a continuous command string, the Decrement command can be followed by any other valid command.

The wiper terminal will move after the command has been received (8th clock).

After the wiper is decremented to the desired position, the \overline{CS} pin should be forced to V_{IH} to ensure that "unexpected" transitions (on the SCK pin <u>do</u> not cause the wiper setting to change). Driving the \overline{CS} pin to V_{IH} should occur as soon as possible (within device specifications) after the last desired decrement occurs.

FIGURE 7-9:

Continuous Decrement Command – SDI and SDO States.

MCP41HVX1

NOTES:

8.0 APPLICATIONS EXAMPLES

Digital potentiometers have a multitude of practical uses in modern electronic circuits. The most popular uses include precision calibration of set point thresholds, sensor trimming, LCD bias trimming, audio attenuation, adjustable power supplies, motor control overcurrent trip setting, adjustable gain amplifiers and offset trimming.

8.1 Split Rail Applications

Split rail applications are when one device operates from one voltage level (rail) and the second device operates from a second voltage level (rail). The typical scenario will be when the microcontroller is operating at a lower voltage level (for power savings, etc) and the MCP41HVX1 is operating at a higher voltage level to maximize operational performance. This configuration is shown in Figure 8-1.

To ensure that communication properly occurs between the devices, care must be done to verify the compatibility of the V_{IL}, V_{IH}, V_{OL}, V_{OH} levels of the interface signals between the devices. These interface signals are:

- <u>CS</u>
- SCK
- SDI
- SDO
- SHDN
- WLAT

When the microcontroller is at a lower voltage rail, the V_{OH} of the microcontroller needs to be greater than the V_{IH} of the MCP41HVX1, and the V_{IL} of the microcontroller needs to be greater than the V_{OL} of the MCP41HVX1.

Table 8-1 shows the calculated maximum MCP41HVX1 VL based on the microcontroller's minimum V_{OH}.

Note: V_{OH} specifications typically have a current load specified. This is due to the pin expected to drive externally circuitry. If the pin is unloaded (or lightly loaded), then the V_{OH} of the pin could approach the device V_{DD} (this is dependent on the implementation of the output driver circuit). For V_{OL} , unloaded (or lightly loaded) pins could approach the device V_{SS} . For V_{OH} and V_{OL} characterization graphs from an example microcontroller, see the PIC16F1934 data sheet (DS41364), Figure 31-15 and Figure 31-16.

FIGURE 8-1: Example

Example Split Rail System.

TABLE 8-1: MCP41HVX1 V_L VOLTAGE BASED ON MICROCONTROLLER V_{OH}

	V _{DD}	1.8V	4.0V					
	V _{DD} - 0.7V	1.1V	2.44V					
	0.7 * V _{DD}	1.89V	4.2V					
2 71/	0.8 * V _{DD}	2.16V	4.8V					
2.1 V	0.9 * V _{DD}	2.43V	5.4V					
	V _{DD}	2.7V	5.5V					

Note 1: The V_{OH} minimum voltage is determined by the load on the pin. If the load is small, a typical output's voltage should approach the device's V_{DD} voltage. This is dependent on the device's output driver design.

> Split Rail voltages are dependent on V_{IL}, V_{IH}, V_{OL}, and V_{OH} of the microcontroller and the MCP41HVX1 devices.

FIGURE 8-2: Example $PIC^{\mathbb{R}}$ Microcontroller V_{OH} Characterization Graph $(V_{DD} = 1.8V)$.

8.2 Using Shutdown Modes

Figure 8-3 shows a possible application circuit where the independent terminals could be used. Disconnecting the wiper allows the transistor input to be taken to the bias voltage level (disconnecting A and or B may be desired to reduce system current). Disconnecting Terminal A modifies the transistor input by the R_{BW} rheostat value to the Common B. Disconnecting Terminal B modifies the transistor input by the R_{AW} rheostat value to the Common A. The Common A and Common B connections could be connected to V+ and V-.

FIGURE 8-3: Example Application Circuit using Terminal Disconnects.

8.3 High-Voltage DAC

A high-voltage DAC can be implemented using the MCP41HVXX, with voltages as high as 36V. The circuit is shown in Figure 8-4. The equation to calculate the voltage output is shown in Figure 8-1.

8.4 Variable Gain Instrumentation Amplifier

A variable gain instrumentation amplifier can be implemented using the MCP41HVXX along with a high voltage dual analog switch and a high voltage instrumentation amplifier.

Figure 8-4. The equation to calculate the voltage output is shown in Figure 8-1.

FIGURE 8-5: Variable Gain Instrumentation Amplifier for Data Acquisition System.

EQUATION 8-2: DAC OUTPUT VOLTAGE CALCULATION

8.5 Audio Volume Control

A digital volume control can be implemented with the MCP41HVXX. Figure 8-6 shows a simple audio volume control implementation.

Figure 8-7 shows a circuit-referenced voltage detect circuit. The output of this circuit could be used to control the Wiper Latch of the MCP41HVXX device in the Audio Volume control circuit to reduce zipper noise or to update the different channels at the same time.

The op amp (U1) could be an MCP6001, while the general purpose comparators (U2 and U3) could be an MCP6541. U4 is a simple AND gate.

U1 establishes the signal zero reference. The <u>upper</u> limit of the comparator is set above its offset. The WLAT pin is forced high whenever the voltage falls between 2.502V and 2.497V (a 0.005V window).

The capacitor C1 AC couples the V_{IN} signal into the circuit, before feeding into the windowed comparator (and MCP41HVXX Terminal A pin).

FIGURE 8-6: Audio Volume Control.

FIGURE 8-7: Referenced Voltage Crossing Detect.

8.6 Programmable Power Supply

The ADP1611 is a step-up DC-to-DC switching converter. Using the MCP41HVXX device allows the power supply to be programmable up to 20V. Figure 8-7 shows a programmable power supply implementation.

Equation 8-3 shows the equation to calculate the output voltage of the programmable power supply. This output is derived from the R_{BW} resistance of the MCP41HVXX device and the R_2 resistor. The ADP1611 will adjust its output voltage to maintain 1.23V on the FB pin.

When power is connected, L1 acts as a short, and V_{OUT} is a diode drop below the +5V voltage. The V_{OUT} voltage will ramp to the programmed value.

FIGURE 8-8: Supply.

Programmable Power

EQUATION 8-3: POWER SUPPLY OUTPUT VOLTAGE CALCULATION

8.7 Programmable Bidirectional Current Source

A programmable bidirectional current source can be implemented with the MCP41HVXX. Figure 8-9 shows an implementation where U1 and U2 work together to deliver the desired current (dependent on selected device) in both directions. The circuit is symmetrical ($R_{1A} = R_{1B}$, $R_{2A} = R_{2B}$, $R_{3A} = R_{3B}$) in order to improve stability. If the resistors are matched, the load current (I_{L}) calculation is shown below:

$$I_{L} = \frac{(R_{2A} + R_{3A})}{R_{1A} * R_{3A}} \times V_{W}$$

FIGURE 8-9: Programmable Bidirectional Current Source.

8.8 LCD Contrast Control

The MCP41HVXX can be used for LCD contrast control. Figure 8-10 shows a simple programmable LCD contrast control implementation.

Some LCD panels support a fixed power supply of up to 28V. The high voltage digital potentiometer's wiper can support contrast adjustments through the entire voltage range.

FIGURE 8-10: Programmable Contrast Control.

8.9 Serial Interface Communication Times

Table 8-2 shows the time for each SPI serial interface command as well as the effective data update rate that can be supported by the digital interface (based on the two SPI serial interface frequencies). So, the Serial Interface performance, along with the wiper response time, would be used to determine your application's volatile Wiper register update rate.

		Example		Com Time	mand e (µs)	Effective Data Update Frequency (kHz) ⁽²⁾	
Command	# of Serial Interface bits	# Bytes Transferred	# of Serial Interface bits	1MHz	10MHz	1MHz	10MHz
Write Single Byte	16	1	16	16	1.6	62,500	625,000
Write Continuous Bytes	N * 16	5	80	80	8	12,500	125,000
Read Byte	16	1	16	16	1.6	62,500	625,000
Read Continuous Bytes	N * 16	5	80	80	8	12,500	125,000
Increment Wiper	8	1	8	8	0.8	125,000	1,250,000
Continuous Increments	N * 8	5	40	40	4	25,000	250,000
Decrement Wiper	8	1	8	8	0.8	125,000	1,250,000
Continuous Decrements	N * 8	5	40	40	4	25,000	250,000

TABLE 8-2: SERIAL INTERFACE TIMES / FREQUENCIES

Note 1: Includes the Start or Stop bits.

2: This is the command frequency multiplied by the number of bytes transferred.

8.10 Design Considerations

In the design of a system with the MCP41HVX1 devices, the following considerations should be taken into account:

- Power Supply Considerations
- Layout Considerations

8.10.1 POWER SUPPLY CONSIDERATIONS

The typical application will require a bypass capacitor in order to filter high-frequency noise, which can be induced onto the power supply's traces. The bypass capacitor helps to minimize the effect of these noise sources on signal integrity. Figure 8-11 illustrates an appropriate bypass strategy.

In this example, the recommended bypass capacitor value is 0.1 $\mu F.$ This capacitor should be placed as close (within 4 mm) to the device power pin (VL) as possible.

The power source supplying these devices should be as clean as possible. If the application circuit has separate digital and analog power supplies, V+ and Vshould reside on the analog plane.

FIGURE 8-11: Typical Microcontroller Connections.

8.10.2 LAYOUT CONSIDERATIONS

In the design of a system with the MCP41HVX1 devices, the following layout considerations should be taken into account:

- Noise
- PCB Area Requirements
- Power Dissipation

8.10.2.1 Noise

Inductively-coupled AC transients and digital switching noise can degrade the input and output signal integrity, potentially masking the MCP41HVX1's performance. Careful board layout minimizes these effects and increases the Signal-to-Noise Ratio (SNR). Multi-layer boards utilizing a low-inductance ground plane, isolated inputs, isolated outputs and proper decoupling are critical to achieving the performance that the silicon is capable of providing. Particularly harsh environments may require shielding of critical signals.

If low noise is desired, breadboards and wire-wrapped boards are not recommended.

8.10.2.2 PCB Area Requirements

In some applications, PCB area is a criteria for device selection. Table 8-3 shows the package dimensions and area for the different package options. The table also shows the relative area factor compared to the smallest area. For space critical applications, the QFN package would be the suggested package.

TABLE 8-3: PACKA	GE FOOTPRINT ⁽ 1)
------------------	------------------------------

		Package Footprint						
nm²)	nsions m)	Dimen (m			Pins			
Area (r	Y	x	Code	Туре				
32.64	6.40	5.10	ST	TSSOP	14			
25.00	5.00	5.00	MQ	QFN	20			
W B B B C C C C C C C C C C	Y 6.40 5.00	(m X 5.10 5.00	Code ST MQ	Type TSSOP QFN	suid 14 20			

Note 1: Does not include recommended land pattern dimensions.

8.10.3 RESISTOR TEMPCO

Characterization curves of the resistor temperature coefficient (Tempco) are shown in the device characterization graphs.

These curves show that the resistor network is designed to correct for the change in resistance as temperature increases. This technique reduces the end-to-end change in R_{AB} resistance.

8.10.3.1 Power Dissipation

The power dissipation of the high-voltage digital potentiometer will most likely be determined by the power dissipation through the resistor networks.

Table 8-4 shows the power dissipation through the resistor ladder (R_{AB}) when Terminal A = +18V and Terminal B = -18V. This is not the worst case power dissipation based on the 25 mA terminal current specification. Table 8-4 show the worst case current (per resistor network), which is independent of the R_{AB} value).

TABLE 8-4: R_{AB} POWER DISSIPATION

R _{AB} I	Resistanc	V _A + V _B	Power	
Typical	Min	Max	= (V)	(mvv) (<u>1</u>)
5,000	4,000	6,000	36	324
10,000	8,000	12,000	36	162
50,000	40,000	60,000	36	32.4
100,000	80,000	120,000	36	16.2

Note 1: Power = $V * I = V^2 / R_{AB(MIN)}$.

TABLE 8-5: R_{BW} POWER DISSIPATION

R _{AB} (Ω) (Typical)	V _W + V _B = (V)	IBW(<mark>2</mark>) (mA)	Power (mW) ⁽ 1 ⁾
5,000	36	25	900
10,000	36	12.5	450
50,000	36	6.5	234
100,000	36	6.5	234

Note 1: Power = V * I.

NOTES:

Technical Documentation

Several additional technical documents are available to

assist you in your design and development. These technical documents include Application Notes,

Technical Briefs, and Design Guides. Table 10-2 shows

10.0 DEVELOPMENT SUPPORT

10.1 Development Tools

Several development tools are available to assist in your design and evaluation of the MCP41HVX1 devices. The currently available tools are shown in Table 10-1.

Figure 10-1 shows how the TSSOP20EV bond-out PCB can be populated to easily evaluate the MCP41HVX1 devices. Evaluation can use the PICkit[™] Serial Analyzer to control the position of the volatile Wiper and state of the TCON register.

Figure 10-2 shows how the SOIC14EV bond-out PCB can be populated to evaluate the MCP41HVX1 devices. The use of the PICkit Serial Analyzer would require blue wire since the header H1 is not compatibly connected.

These boards may be purchased directly from the Microchip web site at www.microchip.com.

TABLE 10-1: DEVELOPMENT TOOLS

Evaluation can use the PICkit[™] trol the position of the volatile TCON register.

some of these documents.

APPENDIX A: REVISION HISTORY

Revision A (May 2013)

· Original Release of this Document.

APPENDIX B: TERMINOLOGY

This appendix discusses the terminology used in this document as well as describes how a parameter is measured.

B.1 Potentiometer (Voltage Divider)

The potentiometer configuration is when all three terminals of the device are tied to different nodes in the circuit. This allows the potentiometer to output a voltage proportional to the input voltage. This configuration is sometimes called voltage divider mode. The potentiometer is used to provide a variable voltage by adjusting the wiper position between the two endpoints as shown in Figure B-1. Reversing the polarity of the A and B terminals will not affect operation.

FIGURE B-1: POTENTIOMETER CONFIGURATION.

The temperature coefficient of the R_{AB} resistors is minimal by design. In this configuration, the resistors all change uniformly, so minimal variation should be seen.

B.2 Rheostat (Variable Resistor)

The rheostat configuration is when two of the three digital potentiometer's terminals are used as a resistive element in the circuit. With terminal W (wiper) and either terminal A or terminal B, a variable resistor is created. The resistance will depend on the tap setting of the wiper (and the wiper's resistance). The resistance is controlled by changing the wiper setting. Figure B-2 shows the two possible resistors that can be used. Reversing the polarity of the A and B terminals will not affect operation.

FIGURE B-2: RHEOSTAT CONFIGURATION.

B.3 Resolution

The resolution is the number of Wiper output states that divide the full-scale range. For the 8-bit digital potentiometer, the resolution is 2^8 , meaning the digital potentiometer Wiper code ranges from 0 to 255.

B.4 Step Resistance (R_S)

The resistance Step size (R_S) equates to one LSb of the resistor ladder. Equation B-1 shows the calculation for the step resistance (R_S) .

EQUATION B-1: R_S CALCULATION

Ideal $R_{S(Ideal)} = \frac{R_{AB}}{2^{N} \cdot 1} \quad \text{or} \quad \frac{(V_A \cdot V_B) / I_{AB}}{2^{N} \cdot 1}$ Measured $R_{S(Measured)} = \frac{(V_{W(@FS)} - V_{W(@ZS)}) / I_{AB}}{2^{N}}$ where: 2^N - 1 = 255 (MCP41HV51/61) = 127 (MCP41HV31/41) V_A = Voltage on Terminal A pin V_B = Voltage on Terminal B pin I_{AB} = Measured Current through A and B pins V_{W(@FS)} = Measured Voltage on W pin at Full-Scale code (FFh or 7Fh) V_{W(@ZS)} = Measured Voltage on W pin at Zero-Scale code (00h)

B.5 Wiper Resistance

Wiper resistance is the series resistance of the analog switch that connects the selected resistor ladder node to the Wiper Terminal common signal (see Figure 5-1).

A value in the volatile wiper register selects which analog switch to close, connecting the W terminal to the selected node of the resistor ladder.

The resistance is dependent on the voltages on the analog switch source, gate, and drain nodes, as well as the device's wiper code, temperature, and the current through the switch. As the device voltage decreases, the wiper resistance increases.

The wiper resistance is measured by forcing a current through the W and B terminals (I_{WB}) and measuring the voltage on the W and A terminals (V_W and V_A). Equation B-2 shows how to calculate this resistance.

EQUATION B-2: R_W CALCULATION $R_{W(Measured)} = \frac{(V_W - V_A)}{I_{WB}}$

where:

- V_A = Voltage on Terminal A pin V_W = Voltage on Terminal W pin
- I_{WB} = Measured current through W and B pins

The wiper resistance in potentiometer-generated voltage divider applications is not a significant source of error (it does not effect the output voltage seen on the W pin).

The wiper resistance in rheostat applications can create significant nonlinearity as the wiper is moved toward zero scale (00h). The lower the nominal resistance, the greater the possible error.

B.6 R_{7S} Resistance

The analog switch between the resistor ladder and the Terminal B pin introduces a resistance, which we call the Zero-Scale resistance (R_{ZS}). Equation B-3 shows how to calculate this resistance.

 $R_{ZS(Measured)} = \frac{(V_{W(@ZS)} - V_B)}{I_{AB}}$ where: V_{W(@ZS)} = Voltage on Terminal W pin at Zero-Scale wiper code V_B = Voltage on Terminal B pin I_{WB} = Measured Current through A and B pins

B.7 R_{FS} Resistance

The analog switch between the resistor ladder and the Terminal A pin introduces a resistance, which we call the Full-Scale resistance (R_{ES}). Equation B-4 shows how to calculate this resistance.

EQUATION B-4: R_{FS} CALCULATION

$$R_{FS(Measured)} = \frac{(V_A - V_{W(@FS)})}{I_{AB}}$$

where: V_A = Voltage on Terminal A pin V_{W(@FS)} = Voltage on Terminal W pin at Full-Scale wiper code

 I_{WB} = Measured Current through A and B pins

B.8 Least Significant Bit (LSb)

This is the difference between two successive codes (either in resistance or voltage). For a given output range it is divided by the resolution of the device (Equation B-5).

EQUATION B-5: LSb CALCULATION

B.9 Monotonic Operation

Monotonic operation means that the device's output (resistance ($R_{BW})$ or voltage ($V_W)$) increases with every one code step (LSb) increment of the wiper register.

FIGURE B-3: THEORETICAL V_W OUTPUT VS CODE (MONOTONIC OPERATION).

B.10 Full-Scale Error (E_{FS})

The Full-Scale Error (see Figure B-5) is the error of the V_W pin relative to the expected V_W voltage (theoretical) for the maximum device Wiper register code (code FFh for 8-bit and code 7Fh for 7-bit), see Equation B-6. The error is dependent on the resistive load on the V_{OUT} pin (and where that load is tied to, such as V_{SS} or V_{DD}). For loads (to V_{SS}) greater than specified, the full scale error will be greater.

The error in bits is determined by the theoretical voltage step size to give an error in LSb.

Note: Analog switch leakage increases with temperature. This leakage increase substantially at higher temperatures (> ~100°C). As analog switch leakage increases, the Full-Scale output value decreases, which increases the Full-Scale Error.

EQUATION B-6: FULL-SCALE ERROR

$$E_{FS} = \frac{V_{W(@FS)} - V_A}{V_{I Sb(IDEAL)}}$$

Where:

 $\begin{array}{l} {\sf E}_{FS} \text{ is expressed in LSb} \\ {\sf V}_{W@FS)} \text{ is the } {\sf V}_W \text{ voltage when the Wiper} \\ & \text{ register code is at Full-scale.} \\ {\sf V}_{IDEAL(@FS)} \text{ is the ideal output voltage when the} \\ & \text{ Wiper register code is at Full-scale.} \\ {\sf V}_{LSb(IDEAL)} \text{ is the theoretical voltage step size.} \end{array}$

FIGURE B-5: FULL-SCALE ERROR EXAMPLE.

B.11 Zero-Scale Error (E_{ZS})

The Zero-Scale Error (see Figure B-6) is the difference between the ideal and measured V_{OUT} voltage with the Wiper register code equal to 00h (Equation B-7). The error is dependent on the resistive load on the V_{OUT} pin (and where that load is tied to, such as V_{SS} or V_{DD}). For loads (to V_{DD}) greater than specified, the zero scale error will be greater.

The error in bits is determined by the theoretical voltage step size to give an error in LSb.

Note: Analog switch leakage increases with temperature. This leakage increase substantially at higher temperatures (> ~100°C). As analog switch leakage increases the Zero-Scale output value decreases, which decreases the Zero-Scale Error.

EQUATION B-7: ZERO SCALE ERROR

B.12 Integral Non-linearity (P-INL) Potentiometer Configuration

The Potentiometer Integral nonlinearity (P-INL) error is the maximum deviation of an actual V_W transfer function from an ideal transfer function (straight line).

In the MCP41HVX1, P-INL is calculated using the Zero-Scale and Full-Scale wiper code end points. P-INL is expressed in LSb. P-INL is also called relative accuracy. Equation B-8 shows how to calculate the P-INL error in LSb and Figure B-7 shows an example of P-INL accuracy.

Positive P-INL means higher V_W voltage than ideal. Negative P-INL means lower V_W voltage than ideal.

Note: Analog switch leakage increases with temperature. This leakage increase substantially at higher temperatures (> ~100°C). As analog switch leakage increases, the Wiper output voltage (V_W) decreases, which effects the INL Error.

EQUATION B-8: P-INL ERROR

F (V _{W(@}	0Co	_{de)} - (V _{LSb(Measured)} * Code))
		V _{LSb(Measured)}
Where:		
NL is expressed	d in	LSb.
Code	=	Wiper Register Value
V _{W(@Code)}	=	The measured V _W output voltage with a given Wiper register code
V _{LSb}	=	For Ideal: V _{AB} / Resolution For Measured: (V _{W(@FS)} - V _{W(@ZS)}) / 255

B.13 Differential Nonlinearity (P-DNL) Potentiometer Configuration

The Potentiometer Differential nonlinearity (P-DNL) error (see Figure B-8) is the measure of V_W step size between codes. The ideal step size between codes is 1 LSb. A P-DNL error of zero would imply that every code is exactly 1 LSb wide. If the P-DNL error is less than 1 LSb, the Digital Potentiometer guarantees monotonic output and no missing codes. The P-DNL error between any two adjacent codes is calculated in Equation B-9.

P-DNL error is the measure of variations in code widths from the ideal code width.

Note: Analog switch leakage increases with temperature. This leakage increase substantially at higher temperatures (> ~100°C). As analog switch leakage increases, the Wiper output voltage (V_W) decreases, which effects the DNL Error.

EQUATION B-9: P-DNL ERROR

B.14 Integral Non-linearity (R-INL) Rheostat Configuration

The Rheostat Integral nonlinearity (R-INL) error is the maximum deviation of an actual R_{BW} transfer function from an ideal transfer function (straight line).

In the MCP41HVX1, INL is calculated using the Zero-Scale and Full-Scale wiper code end points. R-INL is expressed in LSb. R-INL is also called relative accuracy. Equation B-10 shows how to calculate the R-INL error in LSb and Figure B-9 shows an example of R-INL accuracy.

Positive R-INL means higher V_{OUT} voltage than ideal. Negative R-INL means lower V_{OUT} voltage than ideal.

EQUATION B-10: R-INL ERROR

$$E_{INL} = \frac{(R_{BW(@code)} - R_{BW(Ideal)})}{R_{LSb(Ideal)}}$$

Where:

INL is expressed in LSb.

 $R_{BW(Code = n)}$ = The measured R_{BW} resistance with a given wiper register code

 R_{LSb} = For Ideal: R_{AB} / Resolution For Measured: $R_{BW(@FS)}$ / # of R_S

B.15 Differential Nonlinearity (R-DNL) Rheostat Configuration

The Rheostat Differential nonlinearity (R-DNL) error (see Figure B-10) is the measure of R_{BW} step size between codes in actual transfer function. The ideal step size between codes is 1 LSb. A R-DNL error of zero would imply that every code is exactly 1 LSb wide. If the R-DNL error is less than 1 LSb, the R_{BW} Resistance guarantees monotonic output and no missing codes. The R-DNL error between any two adjacent codes is calculated in Equation B-11.

R-DNL error is the measure of variations in code widths from the ideal code width. A R-DNL error of zero would imply that every code is exactly 1 LSb wide.

EQUATION B-11: R-DNL ERROR

B.16 Total Unadjusted Error (E_T)

The Total Unadjusted Error (E_T) is the difference between the ideal and measured V_W voltage. Typically, calibration of the output voltage is implemented to improve system performance.

The error in bits is determined by the theoretical voltage step size to give an error in LSb.

Equation B-12 shows the Total Unadjusted Error calculation.

Note: Analog switch leakage increases with temperature. This leakage increase substantially at higher temperatures (> ~100°C). As analog switch leakage increases, the Wiper output voltage (V_W) decreases, which effects the total Unadjusted Error.

EQUATION B-12: TOTAL UNADJUSTED ERROR CALCULATION

B.17 Settling Time

The Settling time is the time delay required for the V_W voltage to settle into its new output value. This time is measured from the start of code transition, to when the V_W voltage is within the specified accuracy. It is related to the RC characteristics of the resistor ladder and wiper switches.

In the MCP41HVX1, the settling time is a measure of the time delay until the V_W voltage reaches within 0.5 LSb of its final value, when the volatile Wiper Register changes from Zero Scale to Full Scale (or Full Scale to Zero Scale).

B.18 Major-Code Transition Glitch

Major-code transition glitch is the impulse energy injected into the Wiper pin when the code in the Wiper register changes state. It is normally specified as the area of the glitch in nV-Sec, and is measured when the digital code is changed by 1 LSb at the major carry transition (Example: 01111111 to 10000000, or 10000000 to 01111111).

B.19 Digital Feedthrough

The Digital feedthrough is the glitch that appears at the analog output caused by coupling from the digital input pins of the device. The area of the glitch is expressed in nV-Sec, and is measured with a full-scale change (Example: all 0s to all 1s and vice versa) on the digital input pins. The digital feedthrough is measured when the digital potentiometer is not being written to the output register.

B.20 Power-Supply Sensitivity (PSS)

PSS indicates how the output (V_W or R_{BW}) of the digital potentiometer is affected by changes in the supply voltage. PSS is the ratio of the change in V_W to a change in V_{DD} for mid-scale output of the digital potentiometer. The V_W is measured while the V_{DD} is varied from 5.5V to 2.7V as a step, and expressed in % / %, which is the % change of the V_W output voltage with respect to the % change of the V_{DD} voltage.

EQUATION B-13: PSS CALCULATION

$$PSS = \frac{(V_{W(@5.5V)} - V_{W(@2.7V)}) / V_{W(@5.5V)})}{(5.5V - 2.7V) / 5.5V}$$
Where:
PSS is expressed in % / %.

$$V_{W(@5.5V)} = \text{The measured } V_{W} \text{ output } voltage \text{ with } V_{DD} = 5.5V$$

$$V_{W(@2.7V)} = \text{The measured } V_{W} \text{ output } voltage \text{ with } V_{DD} = 2.7V$$

B.21 Power-Supply Rejection Ratio (PSRR)

PSRR indicates how the output of the digital potentiometer is affected by changes in the supply voltage. PSRR is the ratio of the change in V_W to a change in V_{DD} for full-scale output of the digital potentiometer. The V_W is measured while the V_{DD} is varied +/- 10% (V_A and V_B voltages held constant), and expressed in dB or μ V/V.

B.22 Ratiometric Temperature Coefficient

The ratiometric temperature coefficient quantifies the error in the ratio R_{AW}/R_{WB} due to temperature drift. This is typically the critical error when using a digital potentiometer in a voltage divider configuration.

B.23 Absolute Temperature Coefficient

The absolute temperature coefficient quantifies the error in the end-to-end resistance (Nominal resistance R_{AB}) due to temperature drift. This is typically the critical error when using the device in an adjustable resistor configuration.

Characterization curves of the resistor temperature coefficient (Tempco) are shown in Section 2.0 "Typical Performance Curves".

B.24 -3dB Bandwidth

This is the frequency of the signal at the A terminal, that causes the voltage at the W pin to fall -3 dB value from that value of a static value on the A terminal. The output decreases due to the RC characteristics of the resistor network.

B.25 Resistor Noise Density (e_{N WB})

This is the random noise generated by the device's internal resistances. It is specified as a spectral density (voltage per square root Hertz).

PRODUCT IDENTIFICATION SYSTEM

NOTES:

Note the following details of the code protection feature on Microchip devices:

- · Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELOQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and mulfacture of development systems is ISO 9001:2000 certified.

Данный компонент на территории Российской Федерации

Вы можете приобрести в компании MosChip.

Для оперативного оформления запроса Вам необходимо перейти по данной ссылке:

http://moschip.ru/get-element

Вы можете разместить у нас заказ для любого Вашего проекта, будь то серийное производство или разработка единичного прибора.

В нашем ассортименте представлены ведущие мировые производители активных и пассивных электронных компонентов.

Нашей специализацией является поставка электронной компонентной базы двойного назначения, продукции таких производителей как XILINX, Intel (ex.ALTERA), Vicor, Microchip, Texas Instruments, Analog Devices, Mini-Circuits, Amphenol, Glenair.

Сотрудничество с глобальными дистрибьюторами электронных компонентов, предоставляет возможность заказывать и получать с международных складов практически любой перечень компонентов в оптимальные для Вас сроки.

На всех этапах разработки и производства наши партнеры могут получить квалифицированную поддержку опытных инженеров.

Система менеджмента качества компании отвечает требованиям в соответствии с ГОСТ Р ИСО 9001, ГОСТ РВ 0015-002 и ЭС РД 009
