

# Intel® Ethernet Controller I350 Datasheet

## Networking Division (ND)

### Features

#### External Interfaces provided:

- PCIe v2.1 (2.5GT/s and 5GT/s) x4/x2/x1; called PCIe in this document.
- MDI (Copper) standard IEEE 802.3 Ethernet interface for 1000BASE-T, 100BASE-TX, and 10BASE-T applications (802.3, 802.3u, and 802.3ab)
- Serializer-Deserializer (SERDES) to support 1000BASE-SX/LX (optical fiber - IEEE802.3)
- Serializer-Deserializer (SERDES) to support 1000BASE-KX (802.3ap) and 1000BASE-BX (PICMIG 3.1) for Gigabit backplane applications
- SGMII (Serial-GMII Specification) interface for SFP (SFP MSA INF-8074i)/external PHY connections
- NC-SI (DMTF NC-SI) or SMBus for Manageability connection to BMC
- IEEE 1149.6 JTAG

#### Performance Enhancements:

- PCIe v2.1 TLP Process Hints (TPH)
- UDP, TCP and IP Checksum offload
- UDP and TCP Transmit Segmentation Offload (TSO)
- SCTP receive and transmit checksum offload

#### Virtualization ready:

- Next Generation VMDq support (8 VMs)
- Support of up to 8 VMs per port (1 queue allocated to each VM)
- PCI-SIG I/O SR-IOV support (Direct assignment)
- Queues per port: 8 TX and 8 RX queues

#### Power saving features:

- Advanced Configuration and Power Interface (ACPI) power management states and wake-up capability
- Advanced Power Management (APM) wake-up functionality
- Low power link-disconnect state
- PCIe v2.1 LTR
- DMA Coalescing for improved system power management
- EEE (IEEE802.3az) for reduced power consumption during low link utilization periods

#### IEEE802.1AS - Timing and Synchronization:

- IEEE 1588 Precision Time Protocol support
- Per-packet timestamp

#### Total Cost Of Ownership (TCO):

- IPMI BMC pass-thru; multi-drop NC-SI
- Internal BMC to OS and OS to BMC traffic support

#### Additional product details:

- 17x17 (256 Balls) or 25x25 (576 Balls) PBGA package
- Estimated power: 2.8W (max) in dual port mode and 4.2W (max) in quad port mode
- Memories have Parity or ECC protection

Order # 333171-002  
Revision 2.4  
January 2016

# 1 Introduction

The Intel® Ethernet Controller I350 is a single, compact, low power component that supports quad port and dual port gigabit Ethernet designs. The device offers four fully-integrated gigabit Ethernet media access control (MAC), physical layer (PHY) ports and four SGMII/SerDes ports that can be connected to an external PHY. The I350 supports PCI Express\* (PCIe v2.1 (2.5GT/s and 5GT/s)).

The device enables two-port or four port 1000BASE-T implementations using integrated PHY's. It can be used for server system configurations such as rack mounted or pedestal servers, in an add-on NIC or LAN on Motherboard (LOM) design. Another possible system configuration is for blade servers. Here, the I350 can support up to 4 SerDes ports as LOM or mezzanine card. It can also be used in embedded applications such as switch add-on cards and network appliances.

## 1.1 Scope

This document provides the external architecture (including device operation, pin descriptions, register definitions, etc.) for the I350.

This document is a reference for software device driver developers, board designers, test engineers, and others who may need specific technical or programming information.

## 1.2 Terminology and Acronyms

**Table 1-1** Glossary

| Definition     | Meaning                                                                                                                                                                         |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1000BASE-BX    | 1000BASE-BX is the PICMG 3.1 electrical specification for transmission of 1 Gb/s Ethernet or 1 Gb/s fibre channel encoded data over the backplane.                              |
| 1000BASE-KX    | 1000BASE-KX is the IEEE802.3ap electrical specification for transmission of 1 Gb/s Ethernet over the backplane.                                                                 |
| 1000BASE-CX    | 1000BASE-X over specialty shielded 150 $\Omega$ balanced copper jumper cable assemblies as specified in IEEE 802.3 Clause 39.                                                   |
| 1000BASE-T     | 1000BASE-T is the specification for 1 Gb/s Ethernet over category 5e twisted pair cables as defined in IEEE 802.3 clause 40.                                                    |
| AEN            | Asynchronous Event Notification                                                                                                                                                 |
| b/w            | Bandwidth.                                                                                                                                                                      |
| BIOS           | Basic Input/Output System.                                                                                                                                                      |
| BMC            | Baseboard Management Controller (often used interchangeably with MC).                                                                                                           |
| BT             | Bit Time.                                                                                                                                                                       |
| CRC            | Cyclic redundancy check                                                                                                                                                         |
| DCA            | Direct Cache Access.                                                                                                                                                            |
| DFT            | Design for Testability.                                                                                                                                                         |
| DQ             | Descriptor Queue.                                                                                                                                                               |
| DMTF           | Distributed Management Task Force standard body.                                                                                                                                |
| DW             | Double word (4 bytes).                                                                                                                                                          |
| EEE            | Energy Efficient Ethernet - IEEE802.3az standard                                                                                                                                |
| EEPROM         | Electrically Erasable Programmable Memory. A non-volatile memory located on the LAN controller that is directly accessible from the host.                                       |
| EOP            | End of Packet.                                                                                                                                                                  |
| FC             | Flow Control.                                                                                                                                                                   |
| FCS            | Frame Check Sequence.                                                                                                                                                           |
| Firmware (FW)  | Embedded code on the LAN controller that is responsible for the implementation of the NC-SI protocol and pass through functionality.                                            |
| Host Interface | RAM on the LAN controller that is shared between the firmware and the host. RAM is used to pass commands from the host to firmware and responses from the firmware to the host. |
| HPC            | High - Performance Computing.                                                                                                                                                   |
| IPC            | Inter Processor Communication.                                                                                                                                                  |
| IPG            | Inter Packet Gap.                                                                                                                                                               |
| IPMI           | Intelligent Platform Management Interface specification                                                                                                                         |

**Table 1-1 Glossary (Continued)**

| Definition               | Meaning                                                                                                                                                                                          |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LAN (auxiliary Power-Up) | The event of connecting the LAN controller to a power source (occurs even before system power-up).                                                                                               |
| LLDP                     | Link Layer Discovery Protocol defined in IEEE802.1AB used by IEEE802.3az (EEE) for system wake time negotiation.                                                                                 |
| LOM                      | LAN on Motherboard.                                                                                                                                                                              |
| LPI                      | Low Power Idle - Low power state of Ethernet link as defined in IEEE802.3az.                                                                                                                     |
| LSO                      | Large Send Offload.                                                                                                                                                                              |
| LTR                      | Latency Tolerance Reporting (PCIe protocol)                                                                                                                                                      |
| LVR                      | Linear Voltage Regulator                                                                                                                                                                         |
| MAC                      | Media Access Control.                                                                                                                                                                            |
| MC                       | Management Controller                                                                                                                                                                            |
| MCTP                     | DMTF Management Component Transport Protocol (MCTP) specification.<br>A transport protocol to allow communication between a management controller and controlled device over various transports. |
| MDIO                     | Management Data Input/Output Interface over MDC/MDIO lines.                                                                                                                                      |
| MIFS/MIPG                | Minimum Inter Frame Spacing/Minimum Inter Packet Gap.                                                                                                                                            |
| MMW                      | Maximum Memory Window.                                                                                                                                                                           |
| MSS                      | Maximum Segment Size.<br>Largest amount of data, in a packet (without headers) that can be transmitted. Specified in Bytes.                                                                      |
| MPS                      | Maximum Payload Size in PCIe specification.                                                                                                                                                      |
| MTU                      | Maximum Transmit Unit.<br>Largest packet size (headers and data) that can be transmitted. Specified in Bytes.                                                                                    |
| NC                       | Network Controller.                                                                                                                                                                              |
| NC-SI                    | Network Controller Sideband Interface DMTF Specification                                                                                                                                         |
| NIC                      | Network Interface Controller.                                                                                                                                                                    |
| TPH                      | TLP Process Hints (PCIe protocol).                                                                                                                                                               |
| PCS                      | Physical Coding Sub layer.                                                                                                                                                                       |
| PHY                      | Physical Layer Device.                                                                                                                                                                           |
| PMA                      | Physical Medium Attachment.                                                                                                                                                                      |
| PMD                      | Physical Medium Dependent.                                                                                                                                                                       |
| RMII                     | Reduced Media Independent Interface (Reduced MII).                                                                                                                                               |
| SA                       | Source Address.                                                                                                                                                                                  |
| SDP                      | Software Defined Pins.                                                                                                                                                                           |
| SerDes                   | serializer/deserializer. A transceiver that converts parallel data to serial data and vice-versa.                                                                                                |
| SFD                      | Start Frame Delimiter.                                                                                                                                                                           |
| SGMII                    | Serialized Gigabit Media Independent Interface.                                                                                                                                                  |
| SMBus                    | System Management Bus. A bus that carries various manageability components, including the LAN controller, BIOS, sensors and remote-control devices.                                              |
| SVR                      | Switched Voltage Regulator                                                                                                                                                                       |
| TCO                      | Total Cost of Ownership (TCO) System Management.                                                                                                                                                 |
| TLP                      | Transaction Layer Packet in the PCI Express specification.                                                                                                                                       |
| TSO                      | Transmit Segmentation offload - A mode in which a large TCP/UDP I/O is handled to the device and the device segments it to L2 packets according to the requested MSS.                            |
| VLAN                     | Virtual LAN                                                                                                                                                                                      |
| VPD                      | Vital Product Data (PCI protocol).                                                                                                                                                               |

## 1.2.1 External Specification and Documents

The I350 implements features from the following specifications.

### 1.2.1.1 Network Interface Documents

1. IEEE standard 802.3, 2006 Edition (Ethernet). Incorporates various IEEE Standards previously published separately. Institute of Electrical and Electronic Engineers (IEEE).
2. IEEE standard 1149.1, 2001 Edition (JTAG). Institute of Electrical and Electronics Engineers (IEEE)
3. IEEE Std 1149.6-2003, IEEE Standard for Boundary-Scan Testing of Advanced Digital Networks, IEEE, 2003.
4. IEEE standard 802.1Q for VLAN
5. PICMG3.1 Ethernet/Fibre Channel Over PICMG 3.0 Draft Specification, January 14, 2003, Version D1.0
6. Serial-GMII Specification, Cisco Systems document ENG-46158, Revision 1.7
7. INF-8074i Specification for SFP (Small Form factor Pluggable) Transceiver (<ftp://ftp.seagate.com/sff>)
8. IEEE Std 802.3ap-2007
9. IEEE 1588™ Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems, November 8 2002
10. IEEE 802.1AS Timing and Synchronization for Time- Sensitive Applications in Bridged Local Area Networks Draft 2.0, February 22, 2008
11. IEEE 802.3az Energy Efficient Ethernet Draft 1.4, May 2009

### 1.2.1.2 Host Interface Documents

1. PCI-Express 2.1 Base specification
2. PCI Specification, version 3.0
3. PCI Bus Power Management Interface Specification, Rev. 1.2, March 2004
4. Advanced Configuration and Power Interface Specification, Rev 2.0b, October 2002
5. Single Root I/O Virtualization and Sharing Specification Revision 1.1 Draft, September 11, 2007

### 1.2.1.3 Networking Protocol Documents

1. IPv4 specification (RFC 791)
2. IPv6 specification (RFC 2460)
3. TCP/UDP specification (RFC 793/768)
4. SCTP specification (RFC 2960)
5. ARP specification (RFC 826)
6. Neighbor Discovery for IPv6 (RFC 4861)
7. Multicast Listener Discovery (MLD) for IPv6 (RFC 2710)
8. Multicast Listener Discovery Version 2 (MLDv2) for IPv6 (RFC 3810)
9. EUI-64 specification, <http://standards.ieee.org/regauth/oui/tutorials/EUI64.html>.

### 1.2.1.4 Manageability Documents

1. DMTF Network Controller Sideband Interface (NC-SI) Specification rev 1.0.0, May 2009
2. System Management Bus (SMBus) Specification, SBS Implementers Forum, Ver. 2.0, August 2000

## 1.3 Product Overview

The I350 supports 4 SerDes or SGMII ports for MAC to MAC blade server connections or MAC to external PHY connections. Alternatively, four internal 1000BASE-T PHYs can be used to implement a quad port NIC or LOM design.

## 1.4 External Interface

### 1.4.1 PCIe Interface

The PCIe v2.1 (5GT/s) Interface is used by the I350 as a host interface. The interface supports both PCIe v2.1 (2.5GT/s) and PCIe v2.1 (5GT/s) rates and can be configured to x4, x2 and x1. The maximum aggregated raw bandwidth for a typical x4 PCIe v2.1 (5GT/s) configuration is 16 Gb/s in each direction. Refer to [Section 2.3.1](#) for a full pin description. The timing characteristics of this interface are defined in PCI Express Card Electromechanical Specification rev 2.0 and in the PCIe v2.1 (2.5GT/s and 5GT/s) specification.

### 1.4.2 Network Interfaces

Four independent interfaces are used to connect the four I350 ports to external devices. The following protocols are supported:

- MDI (Copper) support for standard IEEE 802.3 Ethernet interface for 1000BASE-T, 100BASE-TX, and 10BASE-T applications (802.3, 802.3u, and 802.3ab)
- SerDes interface to connect over a backplane to another SerDes compliant device or to an Optical module. The I350 supports both 1000BASE-BX and 1000BASE-KX (Without IEEE802.3ap Backplane Auto-Negotiation)
- SGMII interface to attach to an external PHY, either on board or via an SFP module. The SGMII interface shares the same pins as the SerDes

Refer to [Section 2.3.6.2](#) and [Section 2.3.6](#) for full pin description; [Section 11.6.3](#) and [Section](#) for timing characteristics of this interface.

### 1.4.3 EEPROM Interface

The I350 uses an EEPROM device for storing product configuration information. Several words of the EEPROM are accessed automatically by the I350 after reset in order to provide pre-boot configuration data that must be available to the I350 before it is accessed by host software. The remainder of the stored information is accessed by various software modules used to report product configuration, serial number, etc.

The I350 is intended for use with a SPI (4-wire) serial EEPROM device such as an AT25040AN or compatible EEPROM device refer to [Section 11.8.2](#) for full list of supported EEPROM devices. Refer to [Section 2.3.2](#) for full pin description and [Section 11.6.2.5](#) for timing characteristics of this interface.

The I350 also supports an EEPROM-less mode, where all the setup is done by software.

### 1.4.4 Serial Flash Interface

The I350 provides an external SPI serial interface to a Flash or Boot ROM device such as the Atmel\* AT25F1024 or compatible Flash device. Refer to [Section 11.8.1](#) for full list of supported Flash devices. The I350 supports serial Flash devices with up to 64 Mbit (8 MByte) of memory. The size of the Flash used by the I350 can be configured by the EEPROM. Refer to [Section 2.3.2](#) for full pin description and [Section 11.6.2.4](#) for timing characteristics of this interface.

**Note:** Though the I350 supports devices with up to 8 MB of memory, bigger devices can also be used. Accesses to memory beyond the Flash device size results in access wrapping as only the lower address bits are used by the Flash device.

### 1.4.5 SMBus Interface

SMBus is an optional interface for pass-through and/or configuration traffic between a BMC and the I350.

The I350's SMBus interface can be configured to support both slow and fast timing modes. Refer to [Section 2.3.3](#) for full pin description and [Section 11.6.2.2](#) for timing characteristics of this interface.

### 1.4.6 NC-SI Interface

NC-SI and SMBus interfaces are optional for pass-through and/or configuration traffic between a BMC and the I350. The NC-SI interface meets the DMTF NC-SI Specification, Rev. 1.0.0 as an integrated Network Controller (NC) device.

See [Chapter 2.3.4](#) for full pin description and [Chapter 11.6.2.6](#) for timing characteristics of this interface.

### 1.4.7 MDIO/I<sup>2</sup>C 2-Wire Interfaces

The I350 implements four management Interfaces for control of an optional external PHY. Each interface can be either a 2-wire Standard-mode I<sup>2</sup>C interface used to control an SFP module or an MII Management Interface (also known as the Management Data Input/Output or MDIO Interface) for control plane connection between the MAC and PHY devices (master side). This interface provides the MAC and software with the ability to monitor and control the state of the external PHY. The I350 supports the data formats defined in IEEE 802.3 clause 22.

The I350 supports shared MDIO operation and separate MDIO connection. When configured via the *MDICNFG* register to separate MDIO operation each MDIO interface should be connected to the relevant PHY. When configured via the *MDICNFG* register to shared MDIO operation the MDC/MDIO interface of

LAN port 0 can be shared by all ports to support connection to a multi-port PHY with a single MDC/MDIO interface. Refer to [Section 2.3.6](#) for a full pin description, [Section 11.6.2.8](#) for MDIO timing characteristics and [Section 11.6.2.3](#) for I<sup>2</sup>C timing characteristics of this interface.

## 1.4.8 Software-Definable Pins (SDP) Interface (General-Purpose I/O)

The I350 has four software-defined pins (SDP pins) per port that can be used for IEEE1588 auxiliary device connections, control of the SFP optical module interface, passing thermal sensor limit indication and other miscellaneous hardware or software-control purposes. These pins can be individually configurable to act as either standard inputs, general-purpose interrupt (GPI) inputs or output pins. The default direction of each pin is configurable via the EEPROM (refer to [Section 6.2.21](#), [Section 8.2.1](#) and [Section 8.2.3](#)), as well as the default value of all pins configured as outputs. Information on SDP usage can be found in [Section 3.4](#) and [Section 7.9.4](#). Refer to [Section 2.3.5](#) for pin description of this interface.

## 1.4.9 LEDs Interface

The I350 implements four output drivers per port intended for driving external LED circuits. Each of the four LED outputs can be individually configured to select the particular event, state, or activity, which is indicated on that output. In addition, each LED can be individually configured for output polarity as well as for blinking versus non-blinking (steady-state) indication.

The configuration for LED outputs is specified via the LEDCTL register. Furthermore, the hardware-default configuration for all LED outputs can be specified via EEPROM fields (refer to [Section 6.2.18](#) and [Section 6.2.20](#)), thereby supporting LED displays configurable to a particular OEM preference.

Refer to [Section 2.3.6.1](#) for full pin description of this interface.

Refer to [Section 7.5](#) for more detailed description of LED behavior.

## 1.5 Features

[Table 1-2](#) to [Table 1-7](#) list the I350's features and compares them to other LAD products .

**Table 1-2 I350 Network Features**

| Feature                                                                                | I350    | 82580   | 82599                | 82576   |
|----------------------------------------------------------------------------------------|---------|---------|----------------------|---------|
| Half duplex at 10/100 Mb/s operation and full duplex operation at all supported speeds | Y       | Y       | 100 Mb/s full duplex | Y       |
| 10/100/1000 Copper PHY integrated on-chip                                              | 4 ports | 4 ports | N                    | 2 ports |
| Jumbo frames supported                                                                 | Y       | Y       | Y                    | Y       |
| Size of jumbo frames supported                                                         | 9.5 KB  | 9.5 KB  | 16 KB                | 9.5 KB  |
| Flow control support: send/receive PAUSE frames and receive FIFO thresholds            | Y       | Y       | Y                    | Y       |
| Statistics for management and RMON                                                     | Y       | Y       | Y                    | Y       |
| 802.1q VLAN support                                                                    | Y       | Y       | Y                    | Y       |

**Table 1-2 I350 Network Features (Continued)**

| Feature                                                             | I350                   | 82580                  | 82599        | 82576        |
|---------------------------------------------------------------------|------------------------|------------------------|--------------|--------------|
| 802.3az EEE support                                                 | Y                      | N                      | N            | N            |
| MDI Flip                                                            | Y                      | N                      | N/A          | Y            |
| SerDes interface for external PHY connection or system interconnect | 4 ports                | 4 ports                | 2 ports      | 2 ports      |
| 1000BASE-KX interface for Blade Server Backplane connections        | Y                      | Y                      | Y            | N            |
| 802.3ap Backplane Auto-negotiation                                  | N                      | N                      | Y            | N            |
| SGMII interface for external 1000BASE-T PHY connection              | 4 ports                | 4 ports                | 2 ports      | 2 ports      |
| Fiber/copper auto-sense                                             | 4 ports                | 4 ports                | N/A          | 2 ports      |
| SerDes support of non-Auto-Negotiation partner                      | Y                      | Y                      | Y            | Y            |
| SerDes signal detect                                                | Y                      | Y                      | N            | Y            |
| External PHY control I/F<br>MDC/MDIO                                | Shared or per function | Shared or per function | Per function | Per function |
| 2 wire I/F                                                          | Per function           | Per function           | Per function | Per function |

**Table 1-3 I350 Host Interface Features**

| Feature                                                                    | I350                          | 82580                         | 82599                    | 82576          |
|----------------------------------------------------------------------------|-------------------------------|-------------------------------|--------------------------|----------------|
| PCIe revision                                                              | 2.1 (5 Gbps or 2.5 Gbps)      | 2.0 (5 Gbps or 2.5 Gbps)      | 2.0 (5 Gbps or 2.5 Gbps) | 2.0 (2.5 Gbps) |
| PCIe physical layer                                                        | Gen 2                         | Gen 2                         | Gen 2                    | Gen 1          |
| Bus width                                                                  | x1, x2, x4                    | x1, x2, x4                    | x1, x4, x8               | x1, x2, x4     |
| 64-bit address support for systems using more than 4 GB of physical memory | Y                             | Y                             | Y                        | Y              |
| Outstanding requests for Tx buffers per port                               | 24 Per port and for all ports | 24 Per port and for all ports | 16                       | 4              |
| Outstanding requests for Tx descriptors per port                           | 4 Per port and for all ports  | 4 Per port and for all ports  | 8                        | 1              |
| Outstanding requests for Rx descriptors per port                           | 4 Per port and for all ports  | 4 Per port and for all ports  | 4                        | 1              |
| Credits for posted writes                                                  | 4                             | 4                             | 8                        | 2              |
| Max payload size supported                                                 | 512 B                         | 512 B                         | 512 B                    | 512 B          |
| Max request size supported                                                 | 2 KB                          | 2 KB                          | 2 KB                     | 512 B          |
| Link layer retry buffer size                                               | 3.2 KB                        | 3.2 KB                        | 3.2 KB                   | 2 KB           |
| Vital Product Data (VPD)                                                   | Y                             | Y                             | Y                        | Y              |
| End to End CRC (ECRC)                                                      | Y                             | Y                             | Y                        | N              |
| LTR (Latency Tolerance Reporting)                                          | Y                             | Y                             | N                        | N              |
| TPH                                                                        | Y                             | Y                             | N                        | N              |
| CSR access via Configuration space                                         | Y                             | Y                             | N                        | N              |
| ACS (Access Control Services)                                              | Y                             | N                             | N                        | N              |

**Table 1-4 I350 LAN Functions Features**

| Feature                                                                                     | I350   | 82580  | 82599  | 82576  |
|---------------------------------------------------------------------------------------------|--------|--------|--------|--------|
| Programmable host memory receive buffers                                                    | Y      | Y      | Y      | Y      |
| Descriptor ring management hardware for transmit and receive                                | Y      | Y      | Y      | Y      |
| Software controlled global reset bit (resets everything except the configuration registers) | Y      | Y      | Y      | Y      |
| Software Definable Pins (SDP) - per port                                                    | 4      | 4      | 8      | 4      |
| Four SDP pins can be configured as general purpose interrupts                               | Y      | Y      | Y      | Y      |
| Wake up                                                                                     | Y      | Y      | Y      | Y      |
| Flexible wake-up filters                                                                    | 8      | 8      | 6      | 6      |
| Flexible filters for queue assignment in normal operation                                   | 8      | 8      | N      | N      |
| IPv6 wake-up filters                                                                        | Y      | Y      | Y      | Y      |
| Default configuration by the EEPROM for all LEDs for pre-driver functionality               | 4 LEDs | 4 LEDs | 4 LEDs | 4 LEDs |
| LAN function disable capability                                                             | Y      | Y      | Y      | Y      |
| Programmable memory transmit buffers                                                        | Y      | Y      | Y      | Y      |
| Double VLAN                                                                                 | Y      | Y      | Y      | Y      |
| IEEE 1588                                                                                   | Y      | Y      | Y      | Y      |
| Per-Packet Timestamp                                                                        | Y      | Y      | N      | N      |
| TX rate limiting per queue                                                                  | N      | N      | Y      | Y      |

**Table 1-5 I350 LAN Performance Features**

| Feature                                                                                                                        | I350       | 82580      | 82599      | 82576      |
|--------------------------------------------------------------------------------------------------------------------------------|------------|------------|------------|------------|
| TCP segmentation offload<br>Up to 256 KB                                                                                       | Y          | Y          | Y          | Y          |
| iSCSI TCP segmentation offload (CRC)                                                                                           | N          | N          | Y          | N          |
| IPv6 support for IP/TCP and IP/UDP receive checksum offload                                                                    | Y          | Y          | Y          | Y          |
| Fragmented UDP checksum offload for packet reassembly                                                                          | Y          | Y          | Y          | Y          |
| Message Signaled Interrupts (MSI)                                                                                              | Y          | Y          | Y          | Y          |
| Message Signaled Interrupts (MSI-X) number of vectors                                                                          | 25         | 10         | 256        | 25         |
| Packet interrupt coalescing timers (packet timers) and absolute-delay interrupt timers for both transmit and receive operation | Y          | Y          | Y          | Y          |
| Interrupt throttling control to limit maximum interrupt rate and improve CPU utilization                                       | Y          | Y          | Y          | Y          |
| Rx packet split header                                                                                                         | Y          | Y          | Y          | Y          |
| Receive Side Scaling (RSS) number of queues per port                                                                           | Up to 8    | Up to 8    | Up to 16   | Up to 16   |
| Total number of Rx queues per port                                                                                             | 8          | 8          | 128        | 16         |
| Total number of TX queues per port                                                                                             | 8          | 8          | 128        | 16         |
| RX header replication<br>Low latency interrupt<br>DCA support<br>TCP timer interrupts<br>No snoop<br>Relax ordering            | Yes to all | Yes to all | Yes to all | Yes to all |
| TSO interleaving for reduced latency                                                                                           | Y          | Y          | Y          | Y          |

**Table 1-5 I350 LAN Performance Features (Continued)**

| Feature                                    | I350 | 82580 | 82599 | 82576 |
|--------------------------------------------|------|-------|-------|-------|
| Receive side coalescing                    | N    | N     | Y     | N     |
| SCTP receive and transmit checksum offload | Y    | Y     | Y     | Y     |
| UDP TSO                                    | Y    | Y     | Y     | Y     |
| IPSec offload                              | N    | N     | Y     | Y     |

**Table 1-6 I350 Virtualization Features**

| Feature                                                    | I350                    | 82580                  | 82599          | 82576     |
|------------------------------------------------------------|-------------------------|------------------------|----------------|-----------|
| Support for Virtual Machines Device queues (VMDq) per port | 8 pools (single queue)  | 8 pools (single queue) | 16/32/64 pools | 8 pools   |
| L2 MAC address filters (unicast and multicast)             | 32                      | 24                     | 128            | 24        |
| L2 VLAN filters                                            | Per pool                | Per pool               | 64             | Per pool  |
| PCI-SIG SR-IOV                                             | 8 VF                    | N                      | 16/32/64 VF    | 8 VF      |
| Multicast/Broadcast Packet replication                     | Y                       | Y on Receive           | Y              | Y         |
| VM to VM Packet forwarding (Packet Loopback)               | Y                       | N                      | Y              | Y         |
| RSS replication                                            | N                       | N                      | Y              | N         |
| Traffic shaping                                            | N                       | N                      | Y              | Y         |
| MAC and VLAN anti-spoofing                                 | Y                       | N                      | Y              | Y         |
| Malicious driver detection                                 | Y                       | Y                      | N              | N         |
| Per-pool statistics                                        | Y                       | Y                      | Y              | Y         |
| Per-pool off loads                                         | Y                       | Y                      | Y              | Y         |
| Per-pool jumbo support                                     | Y                       | Y                      | Y              | Y         |
| Mirroring rules                                            | 4                       | 4                      | 4              | 4         |
| External switch VEPA support                               | Y                       | Y                      | N              | Y         |
| External switch NIV (VNTAG) support                        | N                       | N                      | N              | N         |
| Promiscuous modes                                          | VLAN, unicast multicast | Multicast              | Multicast      | Multicast |

**Table 1-7 I350 Manageability Features**

| Feature                                                                     | I350 | 82580 | 82599 | Kawela |
|-----------------------------------------------------------------------------|------|-------|-------|--------|
| Advanced pass-through-compatible management packet transmit/receive support | Y    | Y     | Y     | Y      |
| Managed ports on SMBus interface to external BMC                            | 4    | 4     | 2     | 2      |
| Fail-over support over SMBus                                                | N    | N     | Y     | Y      |
| Auto-ARP reply over SMBus                                                   | Y    | N     | Y     | Y      |
| NC-SI Interface to an External BMC                                          | Y    | Y     | Y     | Y      |
| Standard DMTF NC-SI protocol support                                        | Y    | Y     | Y     | Y      |
| DMTF MCTP protocol over SMBus                                               | Y    | N     | N     | N      |
| NC-SI HW arbitration                                                        | Y    | N     | N     | Y      |
| OS to BMC traffic                                                           | Y    | N     | N     | N      |
| L2 address filters                                                          | 2    | 2     | 4     | 2      |
| VLAN L2 filters                                                             | 8    | 8     | 8     | 8      |

**Table 1-7 I350 Manageability Features (Continued)**

| Feature                   | I350                                                                  | 82580 | 82599 | Kawela |
|---------------------------|-----------------------------------------------------------------------|-------|-------|--------|
| EtherType filters         | 4                                                                     | 4     | 4     | 4      |
| Flex L4 port filters      | 8                                                                     | 8     | 16    | 16     |
| Flex TCO filters          | 1                                                                     | 1     | 4     | 4      |
| L3 address filters (IPv4) | 4                                                                     | 4     | 4     | 4      |
| L3 address filters (IPv6) | 4                                                                     | 4     | 4     | 4      |
| Proxying                  | 1 ARP Offload per PF<br>2 NS Offloads per PF<br>2 MLD Offloads per PF | N     | N     | N      |

**Table 1-8 I350 power management Features**

| Feature                                                                    | I350 | 82580 | 82599 | Kawela |
|----------------------------------------------------------------------------|------|-------|-------|--------|
| Magic packet wake-up enable with unique MAC address                        | Y    | Y     | Y     | Y      |
| ACPI register set and power down functionality supporting D0 and D3 states | Y    | Y     | Y     | Y      |
| Full wake-up support (APM and ACPI 2.0)                                    | Y    | Y     | Y     | Y      |
| Smart power down at S0 no link and Sx no link                              | Y    | Y     | Y     | Y      |
| LAN disable functionality                                                  | Y    | Y     | Y     | Y      |
| EEE                                                                        | Y    | N     | N     | N      |
| DMA coalescing                                                             | Y    | N     | N     | N      |

## 1.6 I350 Packaging Options

The I350 is available in multiple packaging options:

1. 17x17 PBGA package (2 ports and 4 ports).
2. 25x25 PBGA package

Table 1-9 lists the differences between features supported by the 17x17 and 25x25 packages.

**Table 1-9 I350 17x17 and 25x25 Package Feature**

| Feature                        | 17x17 Package       | 25x25 Package                   |
|--------------------------------|---------------------|---------------------------------|
| Number of SerDes ports         | 2 Ports and 4 Ports | SerDes and SGMII not supported. |
| Number of Copper ports         | 2 Ports and 4 Ports | 2 Ports (port 0 and 1).         |
| Integrated SVR and LVR control | Supported           | Not supported                   |

## 1.7 Overview of Changes Compared to the 82580

The following section describes modifications done in I350 compared to the 82580.

### 1.7.1 Network Interface

#### 1.7.1.1 Energy Efficient Ethernet (IEEE802.3AZ)

The I350 supports negotiation and link transition to low power Idle (LPI) state as defined in the IEEE802.3az (EEE) standard. EEE is supported for the following technologies:

- 1000BASE-T
- 100BASE-TX

Energy Efficient Ethernet enables reduction of I350 power consumption as a function of link utilization. In addition the I350 enables overall system power reduction as a function of link utilization by reporting increased latency tolerance values via PCIe LTR messages when link is in Low Power Idle state. For more information, refer to [Section 3.7.7](#).

#### 1.7.1.2 MDI Flip

To simplify on-board routing of MDI signals it is sometimes beneficial to be able to swap between MDI Lanes:

- A <-> D.
- B <-> C.

The I350 supports the MDI Flip option in the internal 1000BASE-T PHY. For more information, refer to [Section 8.26.1](#).

### 1.7.2 Virtualization

The virtualization feature set implemented in the I350 is equivalent to the virtualization feature set supported by the 82576 with the following changes.

#### 1.7.2.1 PCI SR IOV

The I350 supports the PCI-SIG Single-Root I/O Virtualization and Sharing specification (SR-IOV) Rev 1.1.

- Support for up to 8 virtual functions (VFs).
- Partial replication of PCI configuration space.

For information, refer to [Section 7.8.2](#).

## 1.7.2.2 Promiscuous VLAN Filtering

The I350 supports promiscuous VLAN filtering per queue. For information, refer to [Section 8.14.17](#).

## 1.7.2.3 Improvements to VMDq Switching

### 1.7.2.3.1 Promiscuous Modes

The I350 adds support for VLAN and unicast promiscuous modes. Refer to [Section 7.8.3.4](#) for details.

### 1.7.2.3.2 Microsoft NLB Mode Support

NLB is a mode defined for Microsoft\* Windows Server Operating System where a unicast address behaves as a multicast address in that it is used by multiple machines. In order to support this mode, it should be possible to forward part of the unicast MAC addresses to the network the same way we do for multicast addresses. In order to support this mode, the *RAH.TRMCS*T bit is added. This bit is used to decide if packets are forwarded to the network even if they are forwarded to local addresses. Refer to [Section 7.8.3.4](#) for details.

## 1.7.2.4 Number of Exact Match Filters

The number of *RAH/RAL* registers was expanded to 32.

## 1.7.2.5 Support for 2K Header Buffer

The I350 supports Rx header buffers of up to 2Kbytes as opposed to 960 bytes in previous products. Refer to [Section 7.1.3.1](#) for details.

## 1.7.2.6 Support for Port Based VLAN

Previous products support port based VLAN by enabling enforcement of the VLAN insertion policy via hardware. To complete this capability, the I350 improves removal of the VLAN tag from received packet, so that the receiving VM is not aware of the VLAN network it belongs to. Refer to [Section 7.8.3.8.1](#) for details.

## 1.7.2.7 Header Split on L2 Header

Added support for Header Split on L2 header using bit *PSRTYPE.PSR\_type0*.

## 1.7.2.8 Updated Pool Decision Algorithm

The I350 includes an improved Pool decision queuing algorithm. Refer to [Section 7.8.3](#) for details.

## 1.7.2.9 Statistics

A counter to count dropped packet per Tx queue (*TQDPC*) was added.

## 1.7.3 HOST Interface

### 1.7.3.1 MSI-X Support

The number of MSI-X vectors supported per function by the I350 changed to 25. When not working in an SR-IOV environment, the number of MSI-X vectors allocated to the PF (Physical function) is 10. When working in a SR-IOV environment, the number of MSI-X vectors per port allocated to the VFs (Virtual Functions) is 24 (3 vectors per VF) and an additional MSI-X vector is allocated to the PF. For further information, refer to [Section 7.3](#).

### 1.7.3.2 ID-Based Ordering

ID-Based Ordering provides opportunity-independent-request-streams to bypass another congested stream, yielding a performance improvement. The new ordering attribute relaxes ordering requirements between unrelated traffic by comparing the Requester/Completer IDs of the associated TLPs. The I350 supports the new ordering ID-Based Ordering (IDO) attribute bit in the TLP header and the relevant configuration bits. For information, refer to [Section 9.5.6.12](#).

### 1.7.3.3 Alternative Routing-ID Interpretation (ARI)

To allow more than eight functions per end point without requesting an internal switch, as usually needed in virtualization scenarios, the I350 supports the PCI-SIG defined ARI capability structure. This capability enables interpretation of the *Device* and *Function* fields as a single identification of a function within the bus. In addition, a new structure used to support the IOV capabilities reporting and control is defined. For further information, refer to [Section 9.6.3](#).

**Note:** Since the OS will sometimes decide on ARI and other PCIe feature support based on the functionality reported in function 0, ARI support and IOV capabilities are reported also when a function is disabled and replaced by a dummy function.

### 1.7.3.4 Link State Related Latency Tolerance Reporting (LTR)

The I350 supports report of increased Latency Tolerance values as a function of Link state. When link is in EEE Low Power Idle state, the I350 will send an updated PCIe LTR message with increased latency tolerance values. For information, refer to [Section 5.9](#) and [Section 9.6.6](#).

### 1.7.3.5 Access Control Services (ACS)

The I350 supports ACS Extended Capability structures on all functions. The I350 reports no support for the various ACS capabilities in the ACS Extended Capability structure. For information, refer to [Section 9.6.7](#).

### 1.7.3.6 ASPM Optionality Compliance Capability

A new capability bit, ASPM (Active State Power Management) Optionality Compliance bit has been added to the I350. Software is permitted to use the bit to help determine whether to enable ASPM or whether to run ASPM compliance tests. New bit indicates that the I350 can optionally support entry to L0s. For information, refer to [Section 9.5.6.7](#).

## 1.7.4 Manageability

### 1.7.4.1 Auto-ARP Reply on SMBus

The I350 can be programmed for auto-ARP reply on reception of ARP request packets and supports sending of gratuitous ARP packets to reduce the traffic over the SMBus BMC interconnect. For information, refer to [Section 10.5.4](#).

### 1.7.4.2 NC-SI Commands.

Support for the NC-SI Get Controller Packet Statistics command and additional OS to BMC and BMC to OS OEM commands were added in the I350.

Support for filtering related NC-SI commands and NC-SI flow control were also added. Refer to [Section 10.6.2](#) for supported NC-SI commands.

#### 1.7.4.2.1 NC-SI Hardware Arbitration

The I350 supports NC-SI HW arbitration between different Network Controller packages.

### 1.7.4.3 OS to BMC Traffic

In previous network controller chips traffic from OS to BMC or BMC to OS needed to pass through an external switch if a dedicated port was allocated for manageability or through a dedicated interface such as an IPMI KCS interface. The I350 supports transmission and reception of traffic internally via the regular pass-through interface used to communicate between the OS and local BMC, without need to utilize a dedicated interface or pass the traffic through an external switch. For information, refer to [Section 10.4](#).

### 1.7.4.4 DMTF MCTP Protocol Over SMBus

The I350 enables reporting and controlling all information exposed in a LOM device via NC-SI using the MCTP protocol over SMBus. The MCTP interface will be used by the BMC to only control the NIC and not for pass through traffic. All network ports are mapped to a single MCTP endpoint on SMBus. For information, refer to [Section 10.7](#).

### 1.7.4.5 Proxying

When system is in low power S3 or S4 state and the I350 is in D3 low power state, the I350 supports Host Protocol Offload as required for Win7 compliance of the following protocols:

1. IPv4 ARP - Single IPv4 address.
2. IPv6 Neighbor Solicitation (NS) - Four IPv6 addresses.
3. When NS protocol offload is enabled IPv6 Multicast Listener Discovery (MLD) - Two MLD Multicast-Address-Specific Queries and also supports response to MLD General Queries.

For further information, refer to [Section 5.7](#).

## 1.7.5 EEPROM Structures

Management related EEPROM structures and other EEPROM words were updated. For further information see [Chapter 6](#).

## 1.7.6 Recovery from Memory Error

The I350 supports recovery from memory error using per port software reset and does not require initiation of a full device reset to recover from a memory error condition. The I350 includes ECC protection on memories to verify data integrity. For further information see [Section 7.6](#).

## 1.7.7 BOM Cost Reduction

### 1.7.7.1 On-Chip 1.8V LVR Control

The I350 includes an on-chip Linear Voltage regulator (LVR) control circuit. Together with an external low cost BJT transistor, circuit can be used to generate a 1.8V power supply without need for a higher cost on-board 1.8V voltage regulator (refer to [Section 3.5](#)).

### 1.7.7.2 On-Chip 1.0V SVR Control

The I350 includes an on-chip Switched Voltage Regulator (SVR) control circuit. Together with external matched P/N MOS power transistors and a LC filter the SVR can be used to generate a 1.0V power supply without need for a higher cost on-board 1.0V voltage regulator (refer to [Section 3.5](#)).

### 1.7.7.3 Thermal Sensor

The I350 implements autonomous on-die thermal management to monitor on-die temperature and react when the temperature exceeds a pre-defined threshold. Thermal management policies and thresholds are loaded from the EEPROM for flexibility. The I350 provides an interface to external devices to read its status through the management sideband interfaces.

Using the on die Thermal Sensor the I350 can be programmed to indicate that device temperature has passed one of 3 thermal trip points by:

- Asserting a SDP pin.
- Sending an interrupt.
- Issuing an Alert to the external BMC.

In addition the I350 can be programmed to reduce link speed if one of the Thermal Trip points has been passed. For further information, refer to [Chapter 3](#).

## 1.8 Device Data Flows

### 1.8.1 Transmit Data Flow

Table 1-10 provides a high level description of all data/control transformation steps needed for sending Ethernet packets to the line.

**Table 1-10 Transmit Data Flow**

| Step | Description                                                                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | The host creates a descriptor ring and configures one of I350's transmit queues with the address location, length, head and tail pointers of the ring (one of 8 available Tx queues).                                                           |
| 2    | The host is requested by the TCP/IP stack to transmit a packet, it gets the packet data within one or more data buffers.                                                                                                                        |
| 3    | The host initializes descriptor(s) that point to the data buffer(s) and have additional control parameters that describe the needed hardware functionality. The host places that descriptor in the correct location at the appropriate Tx ring. |
| 4    | The host updates the appropriate queue tail pointer (TDT)                                                                                                                                                                                       |
| 5    | The I350's DMA senses a change of a specific TDT and as a result sends a PCIe request to fetch the descriptor(s) from host memory.                                                                                                              |
| 6    | The descriptor(s) content is received in a PCIe read completion and is written to the appropriate location in the descriptor queue internal cache.                                                                                              |
| 7    | The DMA fetches the next descriptor from the internal cache and processes its content. As a result, the DMA sends PCIe requests to fetch the packet data from system memory.                                                                    |
| 8    | The packet data is received from PCIe completions and passes through the transmit DMA that performs all programmed data manipulations (various CPU off loading tasks as checksum off load, TSO off load, etc.) on the packet data on the fly.   |
| 9    | While the packet is passing through the DMA, it is stored into the transmit FIFO. After the entire packet is stored in the transmit FIFO, it is forwarded to the transmit switch module.                                                        |
| 10   | If the packet destination is also local, it is sent also to the local switch memory and join the receive path.                                                                                                                                  |
| 11   | The transmit switch arbitrates between host and management packets and eventually forwards the packet to the MAC.                                                                                                                               |
| 12   | The MAC appends the L2 CRC to the packet and sends the packet to the line using a pre-configured interface.                                                                                                                                     |
| 13   | When all the PCIe completions for a given packet are done, the DMA updates the appropriate descriptor(s).                                                                                                                                       |
| 14   | After enough descriptors are gathered for write back or the interrupt moderation timer expires, the descriptors are written back to host memory using PCIe posted writes. Alternatively, the head pointer can only be written back.             |
| 15   | After the interrupt moderation timer expires, an interrupt is generated to notify the host device driver that the specific packet has been read to the I350 and the driver can release the buffers.                                             |

## 1.8.2 Receive Data Flow

Table 1-11 provides a high level description of all data/control transformation steps needed for receiving Ethernet packets.

**Table 1-11 Receive Data Flow**

| Step | Description                                                                                                                                                                                                                                                                                                   |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | The host creates a descriptor ring and configures one of the I350's receive queues with the address location, length, head, and tail pointers of the ring (one of 8 available Rx queues).                                                                                                                     |
| 2    | The host initializes descriptors that point to empty data buffers. The host places these descriptors in the correct location at the appropriate Rx ring.                                                                                                                                                      |
| 3    | The host updates the appropriate queue tail pointer (RDT).                                                                                                                                                                                                                                                    |
| 4    | The I350's DMA senses a change of a specific RDT and as a result sends a PCIe request to fetch the descriptors from host memory.                                                                                                                                                                              |
| 5    | The descriptors content is received in a PCIe read completion and is written to the appropriate location in the descriptor queue internal cache.                                                                                                                                                              |
| 6    | A packet enters the Rx MAC. The RX MAC checks the CRC of the packet.                                                                                                                                                                                                                                          |
| 7    | The MAC forwards the packet to an Rx filter                                                                                                                                                                                                                                                                   |
| 8    | If the packet matches the pre-programmed criteria of the Rx filtering, it is forwarded to the Rx FIFO. VLAN and CRC are optionally stripped from the packet and L3/L4 checksum are checked and the destination queue is fixed.                                                                                |
| 9    | The receive DMA fetches the next descriptor from the internal cache of the appropriate queue to be used for the next received packet.                                                                                                                                                                         |
| 10   | After the entire packet is placed into the Rx FIFO, the receive DMA posts the packet data to the location indicated by the descriptor through the PCIe interface. If the packet size is greater than the buffer size, more descriptors are fetched and their buffers are used for the received packet.        |
| 11   | When the packet is placed into host memory, the receive DMA updates all the descriptor(s) that were used by packet data.                                                                                                                                                                                      |
| 12   | After enough descriptors are gathered for write back or the interrupt moderation timer expires or the packet requires immediate forwarding, the receive DMA writes back the descriptor content along with status bits that indicate the packet information including what off loads were done on that packet. |
| 13   | After the interrupt moderation timer completes or an immediate packet is received, the I350 initiates an interrupt to the host to indicate that a new received packet is already in host memory.                                                                                                              |
| 14   | Host reads the packet data and sends it to the TCP/IP stack for further processing. The host releases the associated buffers and descriptors once they are no longer in use.                                                                                                                                  |

## 2 Pin Interface

### 2.1 Signal Type Notation

Table 2-1 defines I350 signal types.

**Table 2-1 Signal Type Definition**

| Type      | Description                                                                    | DC specification                                                          |
|-----------|--------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| In        | LVTTL input-only signal.                                                       | See <a href="#">section 11.6.1.1</a>                                      |
| Out       | LVTTL Output active driver.                                                    | See <a href="#">section 11.6.1.1</a> and <a href="#">Section 11.6.1.2</a> |
| T/S       | LVTTL bi-directional, tri-state input/output pin.                              | See <a href="#">section 11.6.1.1</a>                                      |
| O/D       | Open Drain allows multiple devices to share line using wired-OR configuration. | See <a href="#">section 11.6.1.3</a>                                      |
| NC-SI-in  | NC-SI compliant input signal                                                   | See <a href="#">section 11.6.1.4</a>                                      |
| NC-SI-out | NC-SI compliant output signal                                                  | See <a href="#">section 11.6.1.4</a>                                      |
| A         | Analog signals                                                                 | See <a href="#">section 11.6.3</a> and <a href="#">Section 11.6.4</a>     |
| A-in      | Analog input signals                                                           | See <a href="#">section 11.6.3</a> and <a href="#">Section 11.6.4</a>     |
| A-out     | Analog output signals                                                          | See <a href="#">section 11.6.3</a> and <a href="#">Section 11.6.4</a>     |
| B         | Input bias                                                                     | See <a href="#">section 11.6.6</a> and <a href="#">Section 11.6.7</a>     |
| PS        | Power Supply                                                                   |                                                                           |

### 2.2 17x17 PBGA Package Pin Assignment

The I350 is packaged in a 17x17 PBGA package with 1.0 mm ball pitch.

#### 2.2.1 PCIe

The AC specification for these pins is described in [Section 11.6.2.10](#).

**Table 2-2 PCIe Pins**

|  | Symbol               | Ball #     | Type | Name and Function                                                                                                                                                                                                    |
|--|----------------------|------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | PE_CLK_p<br>PE_CLK_n | A16<br>A15 | A-in | PCIe Differential Reference Clock in: A 100MHz differential clock input. This clock is used as the reference clock for the PCIe Tx/Rx circuitry and by the PCIe core PLL to generate clocks for the PCIe core logic. |

**Table 2-2 PCIe Pins (Continued)**

|  | Symbol                                    | Ball #          | Type  | Name and Function                                                                                                                                                                                                                                                                                                                                   |
|--|-------------------------------------------|-----------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | PET_0_p<br>PET_0_n                        | A12<br>B12      | A-out | PCIe Serial Data output Lane 0: A serial differential output pair running at a bit rate of 2.5Gb/s or 5Gb/s.                                                                                                                                                                                                                                        |
|  | PET_1_p<br>PET_1_n                        | A11<br>B11      | A-out | PCIe Serial Data output Lane 1: A serial differential output pair running at a bit rate of 2.5Gb/s or 5Gb/s.                                                                                                                                                                                                                                        |
|  | PET_2_p<br>PET_2_n                        | A6<br>B6        | A-out | PCIe Serial Data output Lane 2: A serial differential output pair running at a bit rate of 2.5 Gb/s or 5Gb/s.                                                                                                                                                                                                                                       |
|  | PET_3_p<br>PET_3_n                        | A5<br>B5        | A-out | PCIe Serial Data output Lane 3: A serial differential output pair running at a bit rate of 2.5Gb/s or 5Gb/s.                                                                                                                                                                                                                                        |
|  | PER_0_p<br>PER_0_n                        | A14<br>B14      | A-in  | PCIe Serial Data input Lane 0: A Serial differential input pair running at a bit rate of 2.5Gb/s or 5Gb/s.                                                                                                                                                                                                                                          |
|  | PER_1_p<br>PER_1_n                        | A9<br>B9        | A-in  | PCIe Serial Data input Lane 1: A Serial differential input pair running at a bit rate of 2.5Gb/s or 5Gb/s.                                                                                                                                                                                                                                          |

## 2.2.2 Flash and EEPROM Ports

The AC specification for these pins is described in [Section 11.6.2.4](#) to [Section 11.6.2.5](#).

**Table 2-3 Flash and EEPROM Ports Pins**

|  | Symbol    | Ball # | Type | Name and Function                              |
|--|-----------|--------|------|------------------------------------------------|
|  | FLSH_SI   | B15    | T/S  | Serial Data output to the Flash                |
|  | FLSH_SO   | C15    | In   | Serial Data input from the Flash               |
|  | FLSH_SCK  | B16    | T/S  | Flash serial clock Operates at 15.625MHz.      |
|  | FLSH_CE_N | C16    | T/S  | Flash chip select Output                       |
|  | EE_DI     | E15    | T/S  | Data output to EEPROM                          |
|  | EE_DO     | F15    | In   | Data input from EEPROM                         |
|  | EE_SK     | E16    | T/S  | EEPROM serial clock output Operates at ~2 MHz. |
|  | EE_CS_N   | F16    | T/S  | EEPROM chip select Output                      |

## 2.2.3 System Management Bus (SMB) Interface

The AC specification for these pins is described in [Section 11.6.2.2](#).

**Table 2-4 SMB Interface Pins**

|  | Symbol    | Ball # | Type     | Name and Function                                                                              |
|--|-----------|--------|----------|------------------------------------------------------------------------------------------------|
|  | SMBD      | G3     | T/S, O/D | SMB Data. Stable during the high period of the clock (unless it is a start or stop condition). |
|  | SMBCLK    | E5     | T/S, O/D | SMB Clock. One clock pulse is generated for each data bit transferred.                         |
|  | SMBALRT_N | G4     | T/S, O/D | SMB Alert: acts as an Interrupt pin of a slave device on the SMB                               |

## 2.2.4 NC-SI Interface Pins

The AC specification for these pins is described in [Section 11.6.2.6](#).

**Table 2-5 NC-SI Interface Pins**

|  | Symbol                   | Ball #   | Type      | Name and Function                                                                                                                                                                                                                                   |
|--|--------------------------|----------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | NCSI_CLK_IN              | H1       | NC-SI-In  | NC-SI Reference Clock Input – Synchronous clock reference for receive, transmit and control interface. It is a 50MHz clock +/- 100 ppm.<br>Note: When the I350 drives the NC-SI clock NCSI_CLK_IN should be connected to NCSI_CLK_OUT pin on-board. |
|  | NCSI_CLK_OUT             | H2       | NC-SI-Out | NC-SI Reference Clock Output – Synchronous clock reference for receive, transmit and control interface. It is a 50MHz clock +/- 100 ppm. Serves as a clock source to the BMC and the I350 (when configured so).                                     |
|  | NCSI_CRS_DV              | H3       | NC-SI-Out | CRS/DV – Carrier Sense / Receive Data Valid.                                                                                                                                                                                                        |
|  | NCSI_RXD_1<br>NCSI_RXD_0 | J1<br>H4 | NC-SI-Out | Receive data signals from the I350 to BMC.                                                                                                                                                                                                          |
|  | NCSI_TX_EN               | J2       | NC-SI-In  | Transmit Enable.                                                                                                                                                                                                                                    |
|  | NCSI_TXD_1<br>NCSI_TXD_0 | J4<br>J3 | NC-SI-In  | Transmit data signals from BMC to the I350.                                                                                                                                                                                                         |
|  | NCSI_ARB_IN              | C13      | NC-SI-In  | NC-SI HW arbitration token output pin                                                                                                                                                                                                               |
|  | NCSI_ARB_OUT             | D12      | NC-SI-Out | NC-SI HW arbitration token input pin                                                                                                                                                                                                                |

## 2.2.5 Miscellaneous Pins

The AC specification for the XTAL pins is described in [Section 11.6.5](#).

**Table 2-6 Miscellaneous Pins**

|  | Symbol                               | Ball #               | Type | Name and Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

In this case it is latched at the rising edge of PE_RST# or In-Band PCIe Reset (refer to <a href="#">Section 4.4.4</a>).</li> </ol>                                                                                                                                |

**Table 2-6 Miscellaneous Pins (Continued)**

|  | Symbol                               | Ball #               | Type          | Name and Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--|--------------------------------------|----------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | SDP3_0<br>SDP3_1<br>SDP3_2<br>SDP3_3 | N1<br>N2<br>N3<br>N4 | T/S           | SW Defined Pins for port 3: These pins are reserved pins that are software programmable write/read input/output capability. These default to inputs upon power up, but may have their direction and output values defined in the EEPROM. The SDP bits may be mapped to the General Purpose Interrupt bits when configured as inputs.<br>1. The SDP3_0 pin can be used as a watchdog output indication.<br>2. All the SDP pins can be used as SFP sideband signals (TxDisable, present and TxFault). The I350 does not use these signals; it is available for SW control over SFP.<br>3. The SDP3_1 pin can be used as a strapping option to disable PCIe Function 3. In this case it is latched at the rising edge of PE_RST# or In-Band PCIe Reset (refer to <a href="#">Section 4.4.4</a> ). |
|  | LAN_PWR_GOOD                         | D4                   | In            | LAN Power Good: A 3.3v input signal. A transition from low to high initializes the device into operation. If the internal Power-on-Reset circuit is used to trigger device power-up, this signal should be connected to VCC3P3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|  | MAIN_PWR_OK                          | B2                   | In            | Main Power OK – Indicates that platform main power is up. Must be connected externally to main core 3.3V power.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|  | DEV_OFF_N                            | C4                   | In            | Device Off: Assertion of DEV_OFF_N puts the device in Device Disable mode. This pin is asynchronous and is sampled once the EEPROM is ready to be read following power-up. The DEV_OFF_N pin should always be connected to VCC3P3 to enable device operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|  | XTAL1<br>XTAL2                       | P1<br>P2             | A-In<br>A-out | Reference Clock / XTAL: These pins may be driven by an external 25MHz crystal or driven by a single ended external CMOS compliant 25MHz oscillator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|  | TSENSP                               | R2                   | A-out         | Thermal Diode output; Can be used to measure the I350 on-die temperature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|  | TSENSZ                               | T1                   | GND           | Thermal Diode Ground.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## 2.2.6 SERDES/SGMII Pins

The AC specification for these pins is described in [Section 11.6.3](#).

**Table 2-7 SERDES/SGMII Pins**

|  | Symbol           | Ball #     | Type  | Name and Function                                                                                                                                                                                                                                             |
|--|------------------|------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | SER0_p<br>SER0_n | P16<br>P15 | A-in  | SERDES/SGMII Serial Data input Port 0: Differential SERDES Receive interface.<br>A Serial differential input pair running at 1.25Gb/s. An embedded clock present in this input is recovered along with the data.                                              |
|  | SET0_p<br>SET0_n | R16<br>R15 | A-out | SERDES/SGMII Serial Data output Port 0: Differential SERDES Transmit interface.<br>A serial differential output pair running at 1.25Gb/s. This output carries both data and an embedded 1.25GHz clock that is recovered along with data at the receiving end. |

**Table 2-7 SERDES/SGMII Pins (Continued)**

|  | Symbol           | Ball #     | Type  | Name and Function                                                                                                                                                                                                                                                                                                                                         |
|--|------------------|------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | SRDS_0_SIG_DET   | N13        | In    | Port 0 Signal Detect: Indicates that signal (light) is detected from the Fiber. High for signal detect, Low otherwise.<br>Polarity of Signal Detect pin is controlled by <i>CTRL.ILOS</i> bit.<br>For non-fiber serdes applications link indication is internal, <i>CONNSW.ENRGSR</i> bit should be 0b and pin should be connected to a pull-up resistor. |
|  | SER1_p<br>SER1_n | M16<br>M15 | A-in  | SERDES/SGMII Serial Data input Port 1: Differential fiber SERDES Receive interface.<br>A Serial differential input pair running at 1.25Gb/s. An embedded clock present in this input is recovered along with the data.                                                                                                                                    |

## 2.2.7 SFP Pins

The AC specification for these pins is described in [Section 11.6.2.9](#).

**Table 2-8 SFP Pins**

|  | Symbol        | Ball # | Type     | Name and Function                                                                                               |
|--|---------------|--------|----------|-----------------------------------------------------------------------------------------------------------------|
|  | SFP0_I2C_CLK  | M13    | Out, O/D | Port 0 SFP 2 wire interface clock – connects to Mod-Def1 input of SFP (O/D). Can also be used as MDC pin (Out). |
|  | SFP0_I2C_DATA | J13    | T/S, O/D | Port 0 SFP 2 wire interface data – connects to Mod-Def2 pin of SFP (O/D). Can also be used as MDIO pin (T/S).   |
|  | SFP1_I2C_CLK  | M14    | Out, O/D | Port 1 SFP 2 wire interface clock – connects to Mod-Def1 input of SFP (O/D). Can also be used as MDC pin (Out). |
|  | SFP1_I2C_DATA | N14    | T/S, O/D | Port 1 SFP 2 wire interface data – connects to Mod-Def2 pin of SFP (O/D). Can also be used as MDIO pin (T/S).   |
|  | SFP2_I2C_CLK  | J14    | Out, O/D | Port 2 SFP 2 wire interface clock – connects to Mod-Def1 input of SFP (O/D). Can also be used as MDC pin (Out). |
|  | SFP2_I2C_DATA | H13    | T/S, O/D | Port 2 SFP 2 wire interface data – connects to Mod-Def2 pin of SFP (O/D). Can also be used as MDIO pin (T/S).   |
|  | SFP3_I2C_CLK  | H14    | Out, O/D | Port 3 SFP 2 wire interface clock – connects to Mod-Def1 input of SFP (O/D). Can also be used as MDC pin (Out). |
|  | SFP3_I2C_DATA | G16    | T/S, O/D | Port 3 SFP 2 wire interface data – connects to Mod-Def2 pin of SFP (O/D). Can also be used as MDIO pin (T/S).   |

## 2.2.8 PHY Pins

### 2.2.8.1 LED's

The table below describes the functionality of the LED output pins. Default activity of the LED may be modified in the EEPROM word offsets 1Ch and 1Fh from start of relevant LAN Port section. The LED functionality is reflected and can be further modified in the configuration registers LEDCTL.

**Table 2-9 LED Output Pins**

|  | Symbol | Ball # | Type | Name and Function                                                                                                                                                                                                                                                                                                          |
|--|--------|--------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | LED0_0 | C1     | Out  | Port 0 LED0. Programmable LED which indicates by default Link Up.<br><b>Note:</b> Pin is active low by default, can be programmed via EEPROM (refer to <a href="#">Section 6.2.20</a> ) or LEDCTL register (refer to <a href="#">Section 8.2.9</a> ).                                                                      |
|  | LED0_1 | C2     | Out  | Port 0 LED1. Programmable LED which indicates by default activity (when packets are transmitted or received that match MAC filtering).<br><b>Note:</b> Pin is active low by default, can be programmed via EEPROM (refer to <a href="#">Section 6.2.18</a> ) or LEDCTL register (refer to <a href="#">Section 8.2.9</a> ). |
|  | LED0_2 | C3     | Out  | Port 0 LED2. Programmable LED which indicates by default a 100Mbps Link.<br><b>Note:</b> Pin is active low by default, can be programmed via EEPROM (refer to <a href="#">Section 6.2.20</a> ) or LEDCTL register (refer to <a href="#">Section 8.2.9</a> ).                                                               |

## 2.2.9 Voltage Regulator Pins

The electrical specifications for the SVR and LVR is described in [Section 11.6.9](#).

**Table 2-11 Voltage Regulator Pins**

|  | Symbol       | Ball # | Type  | Name and Function                                                                                                                                                                                                                             |
|--|--------------|--------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | VR_EN        | G14    | T/S   | LVR 1.8V and SVR 1.0V enable<br>In case pin is driven low or left floating it indicates that Internal 1.8V LVR Control circuit and internal 1.0V SVR Control circuit are disabled and the 1.0V and 1.8V power supplies are driven externally. |
|  | SVR_HDRV     | C5     | A-out | Internal 1.0V SVR PFET gate drive Driver output for high-side switch<br>Connected to external PFET power transistor.<br><b>Note:</b> When 1.0V SVR is disabled and the I350 is placed in a 82580 socket, ball is unconnected.                 |
|  | SVR_LDRV     | D5     | A-out | Internal 1.0V SVR NFET gate drive Driver output for low-side switch<br>Connected to external NFET power transistor.<br><b>Note:</b> When 1.0V SVR is disabled and the I350 is placed in a 82580 socket, ball is unconnected.                  |
|  | SVR_SW       | G7     | A-In  | Internal 1.0V SVR Control Voltage switch sense input.<br><b>Note:</b> When 1.0V SVR is disabled and the I350 is placed in a 82580 socket, ball is connected to VSS,                                                                           |
|  | SVR_FB       | G5     | A-In  | Internal 1.0V SVR Control Feedback input.<br><b>Note:</b> When 1.0V SVR is disabled and the I350 is placed in a 82580 socket, ball is connected to VSS.                                                                                       |
|  | SVR_COMP     | F6     | A-out | Internal 1.0V SVR Control Compensation output.<br><b>Note:</b> When 1.0V SVR is disabled and the I350 is placed in a 82580 socket, ball is unconnected.                                                                                       |
|  | LVR_1P8_CTRL | C8     | A-out | Internal 1.8V LVR Control output, connected to external BJT transistor.<br><b>Note:</b> When 1.8V LVR is disabled and the I350 is placed in a 82580 socket, ball is connected to PE_TXVTERM2 (1.8V power supply) or is unconnected,           |

## 2.2.10 Testability Pins

**Table 2-12 Testability Pins**

|  | Symbol         | Ball # | Type     | Name and Function                                                                                                                 |
|--|----------------|--------|----------|-----------------------------------------------------------------------------------------------------------------------------------|
|  | RSVD_TE_VSS    | C12    | In       | Enables test mode. When high test pins are multiplexed on functional signals.<br>In functional mode, must be connected to ground. |

Table 2-12 Testability Pins (Continued)

|  | Symbol     | Ball # | Type | Name and Function                                                                                                                                                                                                                                                                                                                                                                                |
|--|------------|--------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | AUX_PWR    | D15    | T/S  | Auxiliary Power Available:<br>This pin is a strapping option pin, latched at the rising edge of PE_RST# or In-Band PCIe Reset. This pin has an internal weak pull-up resistor. In case this pin is driven high during init time it indicates that Auxiliary Power is available and the device should support D3cold power state if enabled to do so. This pin is also used for testing and scan. |
|  | LAN0_DIS_N | F14    | T/S  | This pin is a strapping option pin, latched at the rising edge of PE_RST# or In-Band PCIe Reset. In case this pin is asserted during init time, LAN 0 function is disabled. This pin is also used for testing and scan. Refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> for additional information.                                                                     |
|  | LAN1_DIS_N | E14    | T/S  | This pin is a strapping option pin, latched at the rising edge of PE_RST# or In-Band PCIe Reset. In case this pin is asserted during init time, LAN 1 function is disabled. This pin is also used for testing and scan. Refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> for additional information.                                                                     |
|  | LAN2_DIS_N | D14    | T/S  | This pin is a strapping option pin, latched at the rising edge of PE_RST# or In-Band PCIe Reset. In case this pin is asserted during init time, LAN 2 function is disabled. Refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> for additional information.                                                                                                                 |
|  | LAN3_DIS_N | C14    | T/S  | This pin is a strapping option pin, latched at the rising edge of PE_RST# or In-Band PCIe Reset. In case this pin is asserted during init time, LAN 3 function is disabled. This pin is also used for testing and scan. Refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> for additional information.                                                                     |
|  | RSVD_JTP8  | G15    | In   | Test pin for production testing. In functional mode should not be connected.                                                                                                                                                                                                                                                                                                                     |

## 2.2.11 Power Supply and Ground Pins

**Table 2-13 Power Supply Pins**

|  | Symbol      | Ball #                                            | Type | Name and Function                               |
|--|-------------|---------------------------------------------------|------|-------------------------------------------------|
|  | VCC3P3      | K5                                                | 3.3V | 3.3V Periphery power supply                     |
|  | VCC3P3      | F5, H5                                            | 3.3V | 3.3V Periphery power supply                     |
|  | VCC3P3      | F12, H12, K12, L12                                | 3.3V | 3.3V Periphery power supply                     |
|  | VCC1P0      | E6, G6, H6, J6, E11, G11, H11, J11, K11, M11, N12 | 1.0V | 1.0V digital power supply                       |
|  | VCC1P0      | K6                                                | 1.0V | 1.0V digital power supply                       |
|  | VCC1P0_APE  | D6, D8, D9, D11                                   | 1.0V | 1.0V PCIe Analog Power Supply                   |
|  | VCC1P0_ASE  | L13, K14, L14                                     | 1.0V | 1.0V SerDes Analog power supply                 |
|  | VCC1P0_AGE  | L7, L8, L9, L10                                   | 1.0V | 1.0V PHY analog power supply                    |
|  | VCC3P3_A    | M6, M7, M8, M9, M10, P8, P11                      | 3.3V | 3.3V PHY analog power supply                    |
|  | VCC3P3_AGE  | L5                                                | 3.3V | 3.3V PHY analog power supply                    |
|  | VCC1P8_PE_1 | C7                                                | 1.8V | PCIe VCO Analog power supply connected to 1.8V. |
|  | VCC1P8_PE_2 | C10                                               | 1.8V | PCIe VCO Analog power supply connected to 1.8V. |

| Signal | Pin                                                                                                                                                                                                                  |

## 2.2.13 2-Port 17x17 PBGA Package Pin List (Alphabetical)

**Note:** 2-port and 4-port 17x17 PBGA packages share the same NVM\_EEPROM images. In the case of the 2 port device the additional EEPROM bits are ignored although the checksums must still be valid.

**Table 2-15 2-Port 17x17 PBGA Package Pin List (Alphabetical)**

| Signal      | Ball | Signal       | Ball | Signal        | Ball |

## 2.3 25x25 PBGA Package Pin Assignment

The I350 is packaged in a 25x25 PBGA package with 1.0 mm ball pitch.

Following tables describe functionality of the various balls.

### 2.3.1 PCIe

The AC specification for these pins is described in [Section 11.6.2.10](#).

**Table 2-17 PCIe Pins**

|  | Symbol               | Ball #       | Type  | Name and Function                                                                                                                                                                                                    |

## 2.3.2 Flash and EEPROM Ports

The AC specification for these pins is described in [Section 11.6.2.4](#) to [Section 11.6.2.5](#).

**Table 2-18 Flash and EEPROM Ports Pins**

|  | Symbol    | Ball # | Type | Name and Function                              |
|--|-----------|--------|------|------------------------------------------------|
|  | FLSH_SI   | K2     | T/S  | Serial Data output to the Flash                |
|  | FLSH_SO   | K1     | In   | Serial Data input from the Flash               |
|  | FLSH_SCK  | J1     | T/S  | Flash serial clock Operates at 15.625MHz.      |
|  | FLSH_CE_N | J2     | T/S  | Flash chip select Output                       |
|  | EE_DI     | R1     | T/S  | Data output to EEPROM                          |
|  | EE_DO     | T1     | In   | Data input from EEPROM                         |
|  | EE_SK     | N2     | T/S  | EEPROM serial clock output Operates at ~2 MHz. |
|  | EE_CS_N   | N3     | T/S  | EEPROM chip select Output                      |

## 2.3.3 System Management Bus (SMB) Interface

The AC specification for these pins is described in [Section 11.6.2.2](#).

**Table 2-19 SMB Interface Pins**

|  | Symbol    | Ball # | Type | Name and Function                                                                              |
|--|-----------|--------|------|------------------------------------------------------------------------------------------------|
|  | SMBD      | L1     | O/D  | SMB Data. Stable during the high period of the clock (unless it is a start or stop condition). |
|  | SMBCLK    | L2     | O/D  | SMB Clock. One clock pulse is generated for each data bit transferred.                         |
|  | SMBALRT_N | M2     | O/D  | SMB Alert: acts as an Interrupt pin of a slave device on the SMB                               |

## 2.3.4 NC-SI Interface Pins

The AC specification for these pins is described in [Section 11.6.2.6](#).

**Table 2-20 NC-SI Interface Pins**

|  | Symbol                   | Ball #   | Type      | Name and Function                                                                                                                                                                                                                                  |
|--|--------------------------|----------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | NCSI_CLK_IN              | G2       | NC-SI-In  | NC-SI Reference Clock Input – Synchronous clock reference for receive, transmit and control interface. It is a 50MHz clock +/- 50 ppm.<br>Note: When the I350 drives the NC-SI clock NCSI_CLK_IN should be connected to NCSI_CLK_OUT pin on-board. |
|  | NCSI_CLK_OUT             | L3       | NC-SI-Out | NC-SI Reference Clock Output – Synchronous clock reference for receive, transmit and control interface. It is a 50MHz clock +/- 50 ppm. Serves as a clock source to the BMC and the I350 (when configured so).                                     |
|  | NCSI_CRS_DV              | H1       | NC-SI-Out | CRS/DV – Carrier Sense / Receive Data Valid.                                                                                                                                                                                                       |
|  | NCSI_RXD_1<br>NCSI_RXD_0 | G1<br>H3 | NC-SI-Out | Receive data signals from the I350 to BMC.                                                                                                                                                                                                         |
|  | NCSI_TX_EN               | G4       | NC-SI-In  | Transmit Enable.                                                                                                                                                                                                                                   |
|  | NCSI_TXD_1<br>NCSI_TXD_0 | G3<br>H2 | NC-SI-In  | Transmit data signals from BMC to the I350.                                                                                                                                                                                                        |
|  | NCSI_ARB_OUT             | F2       | NC-SI-Out | NC-SI HW arbitration token output pin.                                                                                                                                                                                                             |
|  | NCSI_ARB_IN              | F1       | NC-SI-In  | NC-SI HW arbitration token input pin.                                                                                                                                                                                                              |

**Note:** If NC-SI is disconnected: (1) an external pull-down should be used for the NCSI\_CLK\_IN and NCSI\_TX\_EN pins; a pull-down (10 K  $\Omega$ ) should be used for NCSI\_TXD[1:0].

## 2.3.5 Miscellaneous Pins

The AC specification for the XTAL pins is described in [Section 11.6.5](#).

**Table 2-21 Miscellaneous Pins**

|  | Symbol                               | Ball #               | Type | Name and Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--|--------------------------------------|----------------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | SDP0_0<br>SDP0_1<br>SDP0_2<br>SDP0_3 | R4<br>P3<br>T4<br>R3 | T/S  | SW Defined Pins for port 0: These pins are reserved pins that are software programmable write/read input/output capability. These default to inputs upon power up, but may have their direction and output values defined in the EEPROM. The SDP bits may be mapped to the General Purpose Interrupt bits when configured as inputs.<br>1. The SDP0_0 pin can be used as a watchdog output indication.<br>2. All the SDP pins can be used as SFP sideband signals (TxDisable, present and TxFault). The I350 does not use these signals; it is available for SW control over SFP.<br>3. The SDP0_1 pin can be used as a strapping option to disable PCIe Function 0. In this case it is latched at the rising edge of PE_RST# or In-Band PCIe Reset (refer to <a href="#">Section 4.4.4</a> ).<br><b>Note:</b> |

**Table 2-21 Miscellaneous Pins (Continued)**

|  | Symbol                               | Ball #                   | Type          | Name and Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## 2.3.6 PHY Pins

### 2.3.6.1 LED's

The table below describes the functionality of the LED output pins. Default activity of the LED may be modified in the EEPROM word offsets 1Ch and 1Fh from start of relevant LAN Port section. The LED functionality is reflected and can be further modified in the configuration registers LEDCTL.

**Table 2-22 LED Output Pins**

|  | Symbol | Ball # | Type | Name and Function                                                                                                                                                                                                                                     |
|--|--------|--------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | LED0_0 | H4     | Out  | Port 0 LED0. Programmable LED which indicates by default Link Up.<br><b>Note:</b> Pin is active low by default, can be programmed via EEPROM (refer to <a href="#">Section 6.2.20</a> ) or LEDCTL register (refer to <a href="#">Section 8.2.9</a> ). |

Table 2-22 LED Output Pins (Continued)

|  | Symbol | Ball # | Type | Name and Function                                                                                                                                                                                                                                                                                                                 |

## 2.4 Pullups/Pulldowns

The table below lists internal & external pull-up resistors and their functionality in different device states. Each internal PUP has a nominal value of 100K $\Omega$ , ranging from 50K $\Omega$  to 150K $\Omega$ .

The device states are defined as follows:

- Power-up = while 3.3V is stable, yet 1.0V isn't
- Active = normal mode (not power up or disable)
- Disable = device disable (a.k.a. dynamic IDDQ – refer to [Section 4.5](#))

**Table 2-29 Pull-Up Resistors**

| Signal Name  | Power up <sup>5</sup> |          | Active |          | Disable <sup>6</sup> |          | External |
|--------------|-----------------------|----------|--------|----------|----------------------|----------|----------|

**Notes:**

1. Should be pulled down if NC-SI interface is disabled.
2. Only if NC-SI is unused or set to multi drop configuration.
3. If Aux power is connected, should be pulled up, else should be pulled down.
4. If the specific function is disabled, should be pulled down, else should be pulled up.
5. Power up - LAN\_PWR\_GOOD = 0
6. Refer to Section 5.2.6 for description of Disable state.
7. If NC-SI Hardware arbitration is disabled via the NC-SI ARB Enable EEPROM bit (refer to [Section 6.2.22](#)), NCSI\_ARB\_IN pin is pulled-up internally.
8. If SVR and LVR internal control circuitry is enabled should be pulled up, else should be pulled down or not connected
- 9.
10. Signal exists only in 25x25 package.

## 2.5 Strapping

The following signals are used for static configuration. Unless otherwise stated, strapping options are latched on the rising edge of LAN\_PWR\_GOOD, at power up, at in-band PCI Express reset and at PE\_RST\_N assertion. At other times, they revert to their standard usage.

**Table 2-30 Strapping Options**

| Purpose      | Pin        | Behavior                                                                                                    | Pull-up / Pull-down |
|--------------|------------|-------------------------------------------------------------------------------------------------------------|---------------------|
| LAN0 Disable | LAN0_DIS_N | When asserted LAN0 is disabled (refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> ). | Internal pull-up    |
| LAN1 Disable | LAN1_DIS_N | When asserted LAN1 is disabled (refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> ). | Internal pull-up    |

**Table 2-30 Strapping Options (Continued)**

| Purpose                 | Pin                     | Behavior                                                                                                                                                | Pull-up / Pull-down |
|-------------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| LAN2 Disable            | LAN2_DIS_N <sup>1</sup> | When asserted LAN2 is disabled (refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> ).                                             | Internal pull-up    |
| LAN3 Disable            | LAN3_DIS_N <sup>1</sup> | When asserted LAN0 is disabled (refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> ).                                             | Internal pull-up    |
| AUX_PWR                 | AUX_PWR                 | 0b – AUX power is not available<br>1b – AUX power is available                                                                                          | None                |
| PCIe Function 0 Disable | SDP0_1                  | If the <i>en_pin_pcie_func_dis</i> EEPROM bit is set to 1b, when pin is asserted PCIe Function 0 is disabled (refer to <a href="#">Section 4.4.4</a> ). | None                |
| PCIe Function 1 Disable | SDP1_1                  | If the <i>en_pin_pcie_func_dis</i> EEPROM bit is set to 1b, when pin is asserted PCIe Function 1 is disabled (refer to <a href="#">Section 4.4.4</a> ). | None                |
| PCIe Function 2 Disable | SDP2_1 <sup>1</sup>     | If the <i>en_pin_pcie_func_dis</i> EEPROM bit is set to 1b, when pin is asserted PCIe Function 2 is disabled (refer to <a href="#">Section 4.4.4</a> ). | None                |
| PCIe Function 3 Disable | SDP3_1 <sup>1</sup>     | If the <i>en_pin_pcie_func_dis</i> EEPROM bit is set to 1b, when pin is asserted PCIe Function 3 is disabled (refer to <a href="#">Section 4.4.4</a> ). | None                |

1. Only in 17x17 package.

## 3 Interconnects

### 3.1 PCIe

#### 3.1.1 PCIe Overview

PCIe is a third generation I/O architecture that enables cost competitive next generation I/O solutions providing industry leading price/performance and features. It is an industry-driven specification.

PCIe defines a basic set of requirements that encases the majority of the targeted application classes. Higher-end applications' requirements, such as enterprise class servers and high-end communication platforms, are encased by a set of advanced extensions that compliment the baseline requirements.

To guarantee headroom for future applications of PCIe, a software-managed mechanism for introducing new, enhanced, capabilities in the platform is provided. [Figure 3-1](#) shows PCIe architecture.

**Figure 3-1** PCIe Stack Structure

PCIe's physical layer consists of a differential transmit pair and a differential receive pair. Full-duplex data on these two point-to-point connections is self-clocked such that no dedicated clock signals are required. The bandwidth of this interface increases linearly with frequency.

The packet is the fundamental unit of information exchange and the protocol includes a message space to replace the various side-band signals found on many buses today. This movement of hard-wired signals from the physical layer to messages within the transaction layer enables easy and linear physical layer width expansion for increased bandwidth.

The common base protocol uses split transactions and several mechanisms are included to eliminate wait states and to optimize the reordering of transactions to further improve system performance.

### 3.1.1.1 Architecture, Transaction and Link Layer Properties

- Split transaction, packet-based protocol
- Common flat address space for load/store access (such as PCI addressing model)
  - Memory address space of 32-bits to allow compact packet header (must be used to access addresses below 4 GB)
  - Memory address space of 64-bit using extended packet header
- Transaction layer mechanisms:
  - PCI-X style relaxed ordering
  - Optimizations for no-snoop transactions
- Credit-based flow control
- Packet sizes/formats:
  - Maximum upstream (write) payload size of 512 Bytes
  - Maximum downstream (read) payload size of 2 KBytes
- Reset/initialization:
  - Frequency/width/profile negotiation performed by hardware
- Data integrity support
  - Using CRC-32 for transaction layer packets
- Link layer retry for recovery following error detection
  - Using CRC-16 for link layer messages
- No retry following error detection
  - 8b/10b encoding with running disparity
- Software configuration mechanism:
  - Uses PCI configuration and bus enumeration model
  - PCIe-specific configuration registers mapped via PCI extended capability mechanism
- Baseline messaging:
  - In-band messaging of formerly side-band legacy signals (such as interrupts, etc.)
  - System-level power management supported via messages
- Power management:
  - Full support for PCI-PM
  - Wake capability from D3cold state
  - Compliant with ACPI, PCI-PM software model

- Active state power management
- Support for PCIe rev 2.0
  - Support for completion time out
  - Support for additional registers in the PCIe capability structure.

### **3.1.1.2 Physical Interface Properties**

- Point to point interconnect
  - Full-duplex; no arbitration
- Signaling technology:
  - Low Voltage Differential (LVD)
  - Embedded clock signaling using 8b/10b encoding scheme
- Serial frequency of operation: 5 Gbps (Gen2) or 2.5Gbps (Gen1).
- Interface width of x4, x2, or x1.
- DFT and DFM support for high volume manufacturing

### **3.1.1.3 Advanced Extensions**

PCIe defines a set of optional features to enhance platform capabilities for specific usage modes. The I350 supports the following optional features:

- Extended error reporting - messaging support to communicate multiple types/severity of errors.
- Device serial number.
- Completion timeout control.
- TLP Processing Hints (TPH) - provides hints on a per transaction basis to facilitate optimized processing of transactions that target Memory Space.
- Latency Tolerance Reporting (LTR) - messaging support to communicate service latency requirements for Memory Reads and Writes to the Root Complex.

## **3.1.2 Functionality - General**

### **3.1.2.1 Native/Legacy**

All I350 PCI functions are native PCIe functions.

### **3.1.2.2 Locked Transactions**

The I350 does not support locked requests as target or master.

## 3.1.3 Host Interface

### 3.1.3.1 Tag IDs

PCIe device numbers identify logical devices within the physical device (the I350 is a physical device). The I350 implements a single logical device with up to four separate PCI functions: LAN 0, LAN 1, LAN2 and LAN3. The device number is captured from each type 0 configuration write transaction.

Each of the PCIe functions interfaces with the PCIe unit through one or more clients. A client ID identifies the client and is included in the *Tag* field of the PCIe packet header. Completions always carry the tag value included in the request to enable routing of the completion to the appropriate client.

Tag IDs are allocated differently for read and write. Messages are sent with a tag of 0x0.

#### 3.1.3.1.1 TAG ID Allocation for Read Transactions

Table 3-1 lists the Tag ID allocation for read accesses. The tag ID is interpreted by hardware in order to forward the read data to the required device.

**Table 3-1 IDs in Read Transactions**

| Tag ID | Description     | Comment |
|--------|-----------------|---------|
| 0x0    | Data request 0  |         |
| 0x1    | Data request 1  |         |
| 0x2    | Data request 2  |         |
| 0x3    | Data request 3  |         |
| 0x4    | Data request 4  |         |
| 0x5    | Data request 5  |         |
| 0x6    | Data request 6  |         |
| 0x7    | Data request 7  |         |
| 0x8    | Data request 8  |         |
| 0x9    | Data request 9  |         |
| 0xA    | Data request 10 |         |
| 0xB    | Data request 11 |         |
| 0xC    | Data request 12 |         |
| 0xD    | Data request 13 |         |
| 0xE    | Data request 14 |         |
| 0xF    | Data request 15 |         |
| 0x10   | Data request 16 |         |
| 0x11   | Data request 17 |         |
| 0x12   | Data request 18 |         |
| 0x13   | Data request 19 |         |
| 0x14   | Data request 20 |         |
| 0x15   | Data request 21 |         |
| 0x16   | Data request 22 |         |
| 0x17   | Data request 23 |         |
| 0x18   | Descriptor Tx 0 |         |
| 0x19   | Descriptor Tx 1 |         |
| 0x1A   | Descriptor Tx 2 |         |

**Table 3-1 IDs in Read Transactions (Continued)**

|      |                 |  |
|------|-----------------|--|
| 0x1B | Descriptor Tx 3 |  |
| 0x1C | Descriptor Rx 0 |  |
| 0x1D | Descriptor Rx 1 |  |
| 0x1E | Descriptor Rx 2 |  |
| 0x1F | Descriptor Rx 3 |  |

### 3.1.3.1.2 TAG ID Allocation for Write Transactions

Request tag allocation depends on these system parameters:

- DCA supported/not supported in the system (*DCA\_CTRL.DCA\_DIS* - refer to [Section 8.13.4](#) for details)
- TPH enabled in the system.
- DCA enabled/disabled for each type of traffic (*TXCTL.TX Descriptor DCA EN*, *RXCTL.RX Descriptor DCA EN*, *RXCTL.RX Header DCA EN*, *RXCTL.Rx Payload DCA EN*).
- TPH enabled or disabled for the specific type of traffic carried by the TLP (*TXCTL.TX Descriptor TPH EN*, *RXCTL.RX Descriptor TPH EN*, *RXCTL.RX Header TPH EN*, *RXCTL.Rx Payload TPH EN*).
- System type: Legacy DCA vs. DCA 1.0 (*DCA\_CTRL.DCA\_MODE* - refer to [Section 8.13.4](#) for details).
- CPU ID (*RXCTL.CPUID* or *TXCTL.CPUID*).

#### 3.1.3.1.2.1 Case 1 - DCA Disabled in the System:

[Table 3-2](#) describes the write requests tags. Unlike read, the values are for debug only, allowing tracing of requests through the system.

**Table 3-2 IDs in Write Transactions, DCA Disabled Mode**

| Tag ID     | Description                                    |
|------------|------------------------------------------------|
| 0x0 - 0x1  | Reserved                                       |
| 0x2        | Tx descriptors write-back / Tx Head write-back |
| 0x3        | Reserved                                       |
| 0x4        | Rx descriptors write-back                      |
| 0x5        | Reserved                                       |
| 0x6        | Write data                                     |
| 0x7 - 0x1D | Reserved                                       |
| 0x1E       | MSI and MSI-X                                  |
| 0x1F       | Reserved                                       |

#### 3.1.3.1.2.2 Case 2 - DCA Enabled in the System, but Disabled for the Request:

- Legacy DCA platforms - If DCA is disabled for the request, the tags allocation is identical to the case where DCA is disabled in the system. Refer to [Table 3-2](#) above.
- DCA 1.0 platforms - All write requests have a tag value of 0x00.

**Note:** When in DCA 1.0 mode, messages and MSI/MSI-x write requests are sent with the no-hint tag.

### 3.1.3.1.2.3 Case 3 - DCA Enabled in the System, DCA Enabled for the Request:

- Legacy DCA Platforms: the request tag is constructed as follows:
  - Bit[0] - DCA Enable
  - Bits[3:1] - The CPU ID field taken from the CPUID[2:0] bits of the RXCTL or TXCTL registers
  - Bits[7:4] - Reserved
- DCA 1.0 Platforms: the request tag (all 8 bits) is taken from the CPUID field of the RXCTL or TXCTL registers

### 3.1.3.1.2.4 Case 4 - TPH Enabled in the System, TPH Enabled for the Request:

- The request tag (all 8 bits) is taken from the CPUID field of the adequate register or context as described in [Table 7-60](#).

## 3.1.3.2 Completion Timeout Mechanism

In any split transaction protocol, there is a risk associated with the failure of a requester to receive an expected completion. To enable requesters to attempt recovery from this situation in a standard manner, the completion timeout mechanism is defined.

The completion timeout mechanism is activated for each request that requires one or more completions when the request is transmitted. The I350 provides a programmable range for the completion timeout, as well as the ability to disable the completion timeout altogether. The completion timeout is programmed through an extension of the PCIe capability structure (refer to [Section 9.5.6.12](#)).

The I350's reaction in case of a completion timeout is defined in [Table 3-12](#).

The I350 controls the following aspects of completion timeout:

- Disabling or enabling completion timeout.
- Disabling or enabling re-send of a request on completion timeout.
- A programmable range of re-sends on completion timeout, if re-send enabled.
- A programmable range of timeout values.
- Programming the behavior of completion timeout is summarized in [Table 3-12](#). System software may configure completion timeout independently per each LAN function.

**Table 3-3 Completion Timeout Programming**

| Capability                    | Programming capability                                                 |
|-------------------------------|------------------------------------------------------------------------|
| Completion Timeout Enabling   | Controlled through <i>PCI Device Control 2</i> configuration register. |
| Resend Request Enable         | Loaded from the EEPROM into the GCR register.                          |
| Number of re-sends on timeout | Controlled through GCR register.                                       |
| Completion Timeout Period     | Controlled through <i>PCI Device Control 2</i> configuration register. |

Completion Timeout Enable - Programmed through the *PCI Device Control 2* configuration register. The default is: Completion Timeout Enabled.

Resend Request Enable - The *Completion Timeout Resend* EEPROM bit (loaded to the *Completion\_Timeout\_Resend* bit in the PCIe Control register (GCR) enables resending the request (applies only when completion timeout is enabled). The default is to resend a request that timed out.

Number of re-sends on timeout - Programmed through the *Number of resends* field in the GCR register. The default value of resends is 3.

### 3.1.3.2.1 Completion Timeout Period

Programmed through the *PCI Device Control 2* configuration register (refer to [Section 9.5.6.12](#)). The I350 supports all ranges defined by PCIe v2.1 (2.5GT/s and 5GT/s).

A memory read request for which there are multiple completions are considered completed only when all completions have been received by the requester. If some, but not all, requested data is returned before the completion timeout timer expires, the requestor is permitted to keep or to discard the data that was returned prior to timer expiration.

**Note:** The Completion Timeout Value must be programmed correctly in PCIe configuration space (in Device Control 2 Register); the value must be set above the expected maximum latency for completions in the system in which the I350 is installed. This will ensure that the I350 receives the completions for the requests it sends out, avoiding a completion timeout scenario. It is expected that the system BIOS will set this value appropriately for the system.

## 3.1.4 Transaction Layer

The upper layer of the PCIe architecture is the transaction Layer. The transaction layer connects to the I350 core using an implementation specific protocol. Through this core-to-transaction-layer protocol, the application-specific parts of the I350 interact with the PCIe subsystem and transmit and receive requests to or from the remote PCIe agent, respectively.

### 3.1.4.1 Transaction Types Accepted by the I350

**Table 3-4 Transaction Types Accepted by the Transaction Layer**

| Transaction Type            | FC Type     | Tx Later Reaction | Hardware Should Keep Data From Original Packet | For Client          |
|-----------------------------|-------------|-------------------|------------------------------------------------|---------------------|
| Configuration Read Request  | NPH         | CPLH + CPLD       | Requester ID, TAG, Attribute                   | Configuration space |
| Configuration Write Request | NPH + NPD   | CPLH              | Requester ID, TAG, Attribute                   | Configuration space |
| Memory Read Request         | NPH         | CPLH + CPLD       | Requester ID, TAG, Attribute                   | CSR                 |
| Memory Write Request        | PH + PD     | -                 | -                                              | CSR                 |
| IO Read Request             | NPH         | CPLH + CPLD       | Requester ID, TAG, Attribute                   | CSR                 |
| IO Write Request            | NPH + NPD   | CPLH              | Requester ID, TAG, Attribute                   | CSR                 |
| Read completions            | CPLH + CPLD | -                 | -                                              | DMA                 |
| Message                     | PH          | -                 | -                                              | Message Unit / PM   |

Flow control types:

- PH - Posted request headers
- PD - Posted request data payload
- NPH - Non-posted request headers
- NPD - Non-posted request data payload
- CPLH - Completion headers
- CPLD - Completion data payload

#### **3.1.4.1.1 Configuration Request Retry Status**

PCIe supports devices requiring a lengthy self-initialization sequence to complete before they are able to service configuration requests. This is the case for the I350 where initialization is long due to the EEPROM read operation following reset.

If the read of the PCIe section in the EEPROM was not completed and the I350 receives a configuration request, the I350 responds with a configuration request retry completion status to terminate the request, and thus effectively stall the configuration request until the subsystem has completed local initialization and is ready to communicate with the host.

#### **3.1.4.1.2 Partial Memory Read and Write Requests**

The I350 has limited support of read and write requests when only part of the byte enable bits are set as described later in this section.

Partial writes to the MSI-X table are supported. All other partial writes are ignored and silently dropped.

Zero-length writes have no internal impact (nothing written, no effect such as clear-by-write). The transaction is treated as a successful operation (no error event).

Partial reads with at least one byte enabled are answered as a full read. Any side effect of the full read (such as clear by read) is applicable to partial reads also.

Zero-length reads generate a completion, but the register is not accessed and undefined data is returned.

### 3.1.4.2 Transaction Types Initiated by the I350

**Table 3-5 Transaction Types Initiated by the Transaction Layer**

| Transaction type                       | Payload Size        | FC Type     | From Client                 |
|----------------------------------------|---------------------|-------------|-----------------------------|
| Configuration Read Request Completion  | Dword               | CPLH + CPLD | Configuration space         |
| Configuration Write Request Completion | -                   | CPLH        | Configuration space         |
| I/O Read Request Completion            | Dword               | CPLH + CPLD | CSR                         |
| I/O Write Request Completion           | -                   | CPLH        | CSR                         |
| Read Request Completion                | Dword/Qword         | CPLH + CPLD | CSR                         |
| Memory Read Request                    | -                   | NPH         | DMA                         |
| Memory Write Request                   | <= MAX_PAYLOAD_SIZE | PH + PD     | DMA                         |
| Message                                | -                   | PH          | INT / PM / Error Unit / LTR |

**Note:** MAX\_PAYLOAD\_SIZE supported is loaded from EEPROM (128 bytes, 256 bytes or 512 bytes). If ARI capability is not exposed, the effective MAX\_PAYLOAD\_SIZE is defined for each PCI function according to configuration space register of this function. If ARI capability is exposed, effective MAX\_PAYLOAD\_SIZE is defined for all PCI functions according to configuration space register of function zero

#### 3.1.4.2.1 Data Alignment

Requests must never specify an address/length combination that causes a memory space access to cross a 4KB boundary. The I350 breaks requests into 4KB-aligned requests (if needed). This does not pose any requirement on software. However, if software allocates a buffer across a 4KB boundary, hardware issues multiple requests for the buffer. Software should consider limiting buffer sizes and base addresses to comply with a 4KB boundary in cases where it improves performance.

The general rules for packet alignment are as follows:

1. The length of a single request should not exceed the PCIe limit of MAX\_PAYLOAD\_SIZE for write and MAX\_READ\_REQ for read.
2. The length of a single request does not exceed the I350's internal limitation.
3. A single request should not span across different memory pages as noted by the 4 KB boundary previously mentioned.

**Note:** The rules apply to all I350 requests (read/write, snoop and no snoop).

If a request can be sent as a single PCIe packet and still meet rules 1-3, then it is not broken at a cache-line boundary (as defined in the PCIe Cache line size configuration word), but rather, sent as a single packet (motivation is that the chipset might break the request along cache-line boundaries, but the I350 should still benefit from better PCIe utilization). However, if rules 1-3 require that the request is broken into two or more packets, then the request is broken at a cache-line boundary.

#### 3.1.4.2.2 Multiple Tx Data Read Requests (MULR)

The I350 supports 24 pipelined requests for transmit data on all ports. In general, the 24 requests might belong to the same packet or to consecutive packets to be transmitted on a single LAN port or on multiple LAN ports. However, the following restriction applies:

- All requests for a packet are issued before a request is issued for a consecutive packet

Read requests can be issued from any of the supported queues, as long as the restriction is met. Pipelined requests might belong to the same queue or to separate queues. However, as previously noted, all requests for a certain packet are issued (from same queue) before a request is issued for a different packet (potentially from a different queue or LAN port).

The PCIe specification does not ensure that completions for separate requests return in-order. Read completions for concurrent requests are not required to return in the order issued. The I350 handles completions that arrive in any order. Once all completions arrive for a given request, the I350 might issue the next pending read data request.

- The I350 incorporates a re-order buffer to support re-ordering of completions for all requests. Each request/completion can be up to 2 KBytes long. The maximum size of a read request is defined as the minimum {2KB, Max\_Read\_Request\_Size}.

In addition to the 24 pipeline requests for transmit data, the I350 can issue up to 4 read requests for all ports (either for a single port or for multiple LAN ports) to fetch transmit descriptors and 4 read requests for all ports (either for a single LAN port or for multiple LAN ports) to fetch receive descriptors. The requests for transmit data, transmit descriptors, and receive descriptors are independently issued. Each descriptor read request can fetch up to 16 descriptors for reception and 24 descriptors for transmission.

### 3.1.4.3 Messages

#### 3.1.4.3.1 Message Handling by the I350 (as a Receiver)

Message packets are special packets that carry a message code.

The upstream device transmits special messages to the I350 by using this mechanism.

The transaction layer decodes the message code and responds to the message accordingly.

**Table 3-6 Supported Messages in the I350 (as a Receiver)**

| Message code [7:0] | Routing r2r1r0 | Message                                       | Device later response            |
|--------------------|----------------|-----------------------------------------------|----------------------------------|
| 0x14               | 100            | PM_Active_State_NAK                           | Internal signal set              |
| 0x19               | 011            | PME_Turn_Off                                  | Internal signal set              |
| 0x50               | 100            | Slot power limit support (has one Dword data) | Silently drop                    |
| 0x7E               | 010,011,100    | Vendor_defined type 0 no data                 | Unsupported request <sup>1</sup> |
| 0x7E               | 010,011,100    | Vendor_defined type 0 data                    | Unsupported request <sup>1</sup> |
| 0x7F               | 010,011,100    | Vendor_defined type 1 no data                 | Silently drop                    |
| 0x7F               | 010,011,100    | Vendor_defined type 1 data                    | Silently drop                    |
| 0x00               | 011            | Unlock                                        | Silently drop                    |

1. No Completion is expected for this type of packets

#### 3.1.4.3.2 Message Handling by the I350 (as a Transmitter)

The transaction layer is also responsible for transmitting specific messages to report internal/external events (such as interrupts and PMEs).

**Table 3-7 Supported Message in the I350 (as a Transmitter)**

| Message code [7:0] | Routing r2r1r0 | Message      |
|--------------------|----------------|--------------|
| 0x20               | 100            | Assert INT A |
| 0x21               | 100            | Assert INT B |
| 0x22               | 100            | Assert INT C |

**Table 3-7 Supported Message in the I350 (as a Transmitter) (Continued)**

|      |     |                                   |
|------|-----|-----------------------------------|
| 0x23 | 100 | Assert INT D                      |
| 0x24 | 100 | De-assert INT A                   |
| 0x25 | 100 | De-assert INT B                   |
| 0x26 | 100 | De-assert INT C                   |
| 0x27 | 100 | De-Assert INT D                   |
| 0x30 | 000 | ERR_COR                           |
| 0x31 | 000 | ERR_NONFATAL                      |
| 0x33 | 000 | ERR_FATAL                         |
| 0x18 | 000 | PM_PME                            |
| 0x1B | 101 | PME_TO_ACK                        |
| 0x10 | 100 | Latency Tolerance Reporting (LTR) |

### 3.1.4.4 Ordering Rules

The I350 meets the PCIe ordering rules (PCI-X rules) by following the PCI simple device model:

- Deadlock avoidance - Master and target accesses are independent. The response to a target access does not depend on the status of a master request to the bus. If master requests are blocked, such as due to no credits, target completions might still proceed (if credits are available).
- Descriptor/data ordering - The I350 does not proceed with some internal actions until respective data writes have ended on the PCIe link:
  - The I350 does not update an internal header pointer until the descriptors that the header pointer relates to are written to the PCIe link.
  - The I350 does not issue a descriptor write until the data that the descriptor relates to is written to the PCIe link.

The I350 might issue the following master read request from each of the following clients:

- Rx Descriptor Read (up to 4 for all LAN ports)
- Tx Descriptor Read (up to 4 for all LAN ports)
- Tx Data Read (up to 24 for all LAN ports)

Completion of separate read requests are not guaranteed to return in order. Completions for a single read request are guaranteed to return in address order.

#### 3.1.4.4.1 Out of Order Completion Handling

In a split transaction protocol, when using multiple read requests in a multi processor environment, there is a risk that completions arrive from the host memory out of order and interleaved. In this case, the I350 sorts the request completions and transfers them to the Ethernet in the correct order.

### 3.1.4.5 Transaction Definition and Attributes

#### 3.1.4.5.1 Max Payload Size

The I350 policy to determine Max Payload Size (MPS) is as follows:

- Master requests initiated by the I350 (including completions) limits MPS to the value defined for the function issuing the request.

- Target write accesses to the I350 are accepted only with a size of one Dword or two Dwords. Write accesses in the range of (three Dwords, MPS, etc.) are flagged as UR. Write accesses above MPS are flagged as malformed.

Refer to Section 2.2.2 - TLPs with Data Payloads - Rules of the PCIe base specification.

### 3.1.4.5.2 Relaxed Ordering

The I350 takes advantage of the relaxed ordering rules in PCIe. By setting the relaxed ordering bit in the packet header, the I350 enables the system to optimize performance in the following cases:

- Relaxed ordering for descriptor and data reads: When the I350 emits a read transaction, its split completion has no ordering relationship with the writes from the CPUs (same direction). It should be allowed to bypass the writes from the CPUs.
- Relaxed ordering for receiving data writes: When the I350 issues receive DMA data writes, it also enables them to bypass each other in the path to system memory because software does not process this data until their associated descriptor writes complete.
- The I350 cannot relax ordering for descriptor writes, MSI/MSI-X writes or PCIe messages.

Relaxed ordering can be used in conjunction with the no-snoop attribute to enable the memory controller to advance non-snoop writes ahead of earlier snooped writes.

Relaxed ordering is enabled in the I350 by clearing the *RO\_DIS* bit in the *CTRL\_EXT* register. Actual setting of relaxed ordering is done for LAN traffic by the host through the DCA registers.

### 3.1.4.5.3 Snoop Not Required

The I350 sets the *Snoop Not Required* attribute bit for master data writes. System logic might provide a separate path into system memory for non-coherent traffic. The non-coherent path to system memory provides higher, more uniform, bandwidth for write requests.

**Note:** The *Snoop Not Required* attribute does not alter transaction ordering. Therefore, to achieve maximum benefit from *Snoop Not Required* transactions, it is advisable to set the relaxed ordering attribute as well (assuming that system logic supports both attributes). In fact, some chipsets require that relaxed ordering is set for no-snoop to take effect.

Global no-snoop support is enabled in the I350 by clearing the *NS\_DIS* bit in the *CTRL\_EXT* register. Actual setting of no snoop is done for LAN traffic by the host through the DCA registers.

### 3.1.4.5.4 No Snoop and Relaxed Ordering for LAN Traffic

Software might configure non-snoop and relax order attributes for each queue and each type of transaction by setting the respective bits in the *RXCTRL* and *TXCTRL* registers.

Table 3-8 lists Software configuration for the *No-Snoop* and *Relaxed Ordering* bits for LAN traffic when I/OAT 2 is enabled.

**Table 3-8 LAN Traffic Attributes**

| Transaction              | No-Snoop | Relaxed Ordering | Comments                                              |
|--------------------------|----------|------------------|-------------------------------------------------------|
| Rx Descriptor Read       | N        | Y                |                                                       |
| Rx Descriptor Write-Back | N        | N                | Relaxed ordering must never be used for this traffic. |
| Rx Data Write            | Y        | Y                | Refer to Note 1 below and Section 3.1.4.5.4.1         |
| Rx Replicated Header     | N        | Y                |                                                       |

**Table 3-8 LAN Traffic Attributes (Continued)**

|                          |   |   |  |
|--------------------------|---|---|--|
| Tx Descriptor Read       | N | Y |  |
| Tx Descriptor Write-Back | N | Y |  |
| Tx TSO Header Read       | N | Y |  |
| Tx Data Read             | N | Y |  |

**Note:**

1. Rx payload no-snoop is also conditioned by the *NSE* bit in the receive descriptor. Refer to [Section 3.1.4.5.4.1](#).

**3.1.4.5.4.1 No-Snoop Option for Payload**

Under certain conditions, which occur when I/OAT is enabled, software knows that it is safe to transfer (DMA) a new packet into a certain buffer without snooping on the front-side bus. This scenario typically occurs when software is posting a receive buffer to hardware that the CPU has not accessed since the last time it was owned by hardware. This might happen if the data was transferred to an application buffer by the I/OAT DMA engine.

In this case, software should be able to set a bit in the receive descriptor indicating that the I350 should perform a no-snoop DMA transfer when it eventually writes a packet to this buffer.

When a non-snoop transaction is activated, the TLP header has a non-snoop attribute in the *Transaction Descriptor* field.

This is triggered by the *NSE* bit in the receive descriptor. Refer to [Section 7.1.4.2](#).

**3.1.4.5.5 TLP processing Hint (TPH)**

The TPH bit can be set to provide information to the root complex about the cache in which the data should be stored or from which the data should be read as described in [Section 7.7.2](#).

TPH is enabled via the TPH Requester Enable field in the TPH control register of the configuration space (refer to [Section 9.6.5.3](#)). Setting of the TPH bit for different type of traffic is described in [Table 7-60](#).

**3.1.4.6 Flow Control****3.1.4.6.1 I350 Flow Control Rules**

The I350 implements only the default Virtual Channel (VC0). A single set of credits is maintained for VC0.

**Table 3-9 Allocation of FC Credits**

| Credit Type                     | Operations                                                                                | Number Of Credits                                                   |
|---------------------------------|-------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| Posted Request Header (PH)      | Target Write (one unit)<br>Message (one unit)                                             | 16 credit units to support tail write at wire speed.                |
| Posted Request Data (PD)        | Target Write (Length/16 bytes=1)<br>Message (one unit)                                    | MAX_PAYLOAD_SIZE/16                                                 |
| Non-Posted Request Header (NPH) | Target Read (one unit)<br>Configuration Read (one unit)<br>Configuration Write (one unit) | Four units (to enable concurrent target accesses to all LAN ports). |
| Non-Posted Request Data (NPD)   | Configuration Write (one unit)                                                            | Four units.                                                         |
| Completion Header (CPLH)        | Read Completion (N/A)                                                                     | Infinite (accepted immediately).                                    |
| Completion Data (CPLD)          | Read Completion (N/A)                                                                     | Infinite (accepted immediately).                                    |

Rules for FC updates:

- The I350 maintains four credits for NPD at any given time. It increments the credit by one after the credit is consumed and sends an UpdateFC packet as soon as possible. UpdateFC packets are scheduled immediately after a resource is available.
- The I350 provides four credits for PH (such as for four concurrent target writes) and four credits for NPH (such as for four concurrent target reads). UpdateFC packets are scheduled immediately after a resource becomes available.
- The I350 follows the PCIe recommendations for frequency of UpdateFC FCPs.

#### 3.1.4.6.2 Upstream Flow Control Tracking

The I350 issues a master transaction only when the required FC credits are available. Credits are tracked for posted, non-posted, and completions (the later to operate with a switch).

#### 3.1.4.6.3 Flow Control Update Frequency

In any case, UpdateFC packets are scheduled immediately after a resource becomes available.

When the link is in the L0 or L0s link state, Update FCPs for each enabled type of non-infinite FC credit must be scheduled for transmission at least once every 30  $\mu$ s (-0%/+50%), except when the *Extended Sync* bit of the Control Link register is set, in which case the limit is 120  $\mu$ s (-0%/+50%).

#### 3.1.4.6.4 Flow Control Timeout Mechanism

The I350 implements the optional FC update timeout mechanism.

The mechanism is activated when the Link is in L0 or L0s Link state. It uses a timer with a limit of 200 $\mu$ s (-0%/+50%), where the timer is reset by the receipt of any Init or Update FCP. Alternately, the timer may be reset by the receipt of any DLLP.

After timer expiration, the mechanism instructs the PHY to re-establish the link (via the LTSSM recovery state).

#### 3.1.4.7 Error Forwarding

If a TLP is received with an error-forwarding trailer (Poisoned TLP received), the transaction may either be resent or dropped and not delivered to its destination, depending on the *GCR.Completion Timeout resend enable* bit and the *GCR.Number of resends* field. If the re-sends were unsuccessful or if re-send is disabled, the I350 does not initiate any additional master requests for that PCI function until it detects an internal reset or a software reset for the associated LAN. Software is able to access device registers after such a fault.

System logic is expected to trigger a system-level interrupt to inform the operating system of the problem. The operating system can then stop the process associated with the transaction, re-allocate memory instead of the faulty area, etc.

## 3.1.5 Data Link Layer

### 3.1.5.1 ACK/NAK Scheme

The I350 will send ACK/NAK immediately in the following cases:

1. NAK needs to be sent.
2. ACK for duplicate packet
3. ACK/NAK before low power state entry

In all other cases, the I350 will schedule ACK transmission according to time-outs specified in the PCIe specification (depends on link speed, link width, and max\_payload\_size).

### 3.1.5.2 Supported DLLPs

The following DLLPs are supported by the I350 as a receiver:

**Table 3-10 DLLPs Received by the I350**

| DLLP type      | Remarks                |
|----------------|------------------------|
| Ack            |                        |
| Nak            |                        |
| PM_Request_Ack |                        |
| InitFC1-P      | Virtual Channel 0 only |
| InitFC1-NP     | Virtual Channel 0 only |
| InitFC1-Cpl    | Virtual Channel 0 only |
| InitFC2-P      | Virtual Channel 0 only |
| InitFC2-NP     | Virtual Channel 0 only |
| InitFC2-Cpl    | Virtual Channel 0 only |
| UpdateFC-P     | Virtual Channel 0 only |
| UpdateFC-NP    | Virtual Channel 0 only |
| UpdateFC-Cpl   | Virtual Channel 0 only |

The following DLLPs are supported by the I350 as a transmitter:

**Table 3-11 DLLPs Initiated by the I350**

| DLLP type                  | Remarks                |
|----------------------------|------------------------|
| Ack                        |                        |
| Nak                        |                        |
| PM_Enter_L1                |                        |
| PM_Enter_L23               |                        |
| PM_Active_State_Request_L1 |                        |
| InitFC1-P                  | Virtual Channel 0 only |
| InitFC1-NP                 | Virtual Channel 0 only |
| InitFC1-Cpl                | Virtual Channel 0 only |
| InitFC2-P                  | Virtual Channel 0 only |
| InitFC2-NP                 | Virtual Channel 0 only |

**Table 3-11 DLLPs Initiated by the I350 (Continued)**

| DLLP type   | Remarks                |
|-------------|------------------------|
| InitFC2-Cpl | Virtual Channel 0 only |
| UpdateFC-P  | Virtual Channel 0 only |
| UpdateFC-NP | Virtual Channel 0 only |

**Note:** UpdateFC-Cpl is not sent because of the infinite FC-Cpl allocation.

### 3.1.5.3 Transmit EDB Nullifying

In case of a necessity to re-train, there is a need to guarantee that no abrupt termination of the Tx packet happens. For this reason, early termination of the transmitted packet is possible. This is done by appending an EDB (EnD Bad symbol) to the packet.

## 3.1.6 Physical Layer

### 3.1.6.1 Link Speed

The I350 supports 2.5GT/s and 5GT/s link speeds. The following PCIe configuration bits define the link speed:

- *Max Link Speed* bit in the *Link CAP* register — Indicates the link speed supported by the I350 as determined by the *Disable PCIe Gen 2* bit in the *PCIe PHY Auto Configuration* EEPROM section.
- *Link Speed* bit in the *Link Status* register — Indicates the negotiated Link speed.
- *Target Link Speed* bit in the *Link Control 2* register — used to set the target compliance mode speed when software is using the *Enter Compliance* bit to force a link into compliance mode. The default value is determined by the *Disable PCIe Gen 2* bit in the *PCIe PHY Auto Configuration* EEPROM section.

The I350 does not initiate a hardware autonomous speed change and as a result the *Hardware Autonomous Speed Disable* bit in the *PCIe Link Control 2* register is hardwired to 0b.

The I350 supports entering compliance mode at the speed indicated in the *Target Link Speed* field in the *PCIe Link Control 2* register. Compliance mode functionality is controlled via the *Enter Compliance* bit in the *PCIe Link Control 2* register.

### 3.1.6.2 Link Width

The I350 supports a maximum link width of x4, x2, or x1 as determined by the *Disable Lane* bits in the *PCIe PHY Auto Configuration* EEPROM section.

The max link width is loaded into the *Maximum Link Width* field of the *PCIe Capability* register (LCAP[11:6]). The hardware default is x4 link.

During link configuration, the platform and the I350 negotiate on a common link width. The link width must be one of the supported PCIe link widths (x1, x2, x4), such that:

- If *Maximum Link Width* = x4, then the I350 negotiates to either x4, x2 or x1.<sup>1</sup>

1. See restriction in [Section 3.1.6.6](#).

- If *Maximum Link Width* = x2, then the I350 negotiates to either x2 or x1.
- If *Maximum Link Width* = x1, then the I350 only negotiates to x1.

### 3.1.6.3 Polarity Inversion

If polarity inversion is detected, the receiver must invert the received data.

During the training sequence, the receiver looks at Symbols 6-15 of TS1 and TS2 as the indicator of lane polarity inversion (D+ and D- are swapped). If lane polarity inversion occurs, the TS1 Symbols 6-15 received are D21.5 as opposed to the expected D10.2. Similarly, if lane polarity inversion occurs, Symbols 6-15 of the TS2 ordered set are D26.5 as opposed to the expected D5.2. This provides clear indication of lane polarity inversion.

### 3.1.6.4 L0s Exit latency

The number of FTS sequences (N\_FTS) sent during L1 exit, can be loaded from the EEPROM.

### 3.1.6.5 Lane-to-Lane De-Skew

A multi-lane link might have many sources of lane to lane skew. Although symbols are transmitted simultaneously on all lanes, they cannot be expected to arrive at the receiver without lane-to-lane skew. The lane-to-lane skew can include components, which are less than a bit time, bit time units (400/200 ps for 2.5/5 Gbps), or full symbol time units (4 ns) of skew caused by the re-timing repeaters' insert/delete operations. Receivers use TS1 or TS2 or Skip Ordered Sets (SOS) to perform link de-skew functions.

The I350 supports de-skew of up to 12 symbol times (48 ns for 2.5 Gbps link rate and 24 ns for 5Gbps link rate).

### 3.1.6.6 Lane Reversal

The following lane reversal modes are supported (see [Figure 3-2](#)):

- Lane configuration of x4, x2, and x1.
- Lane reversal in x4, x2 and in x1.
- Degraded mode (downshift) from x4 to x2 to x1 and from x2 to x1, with one restriction - if lane reversal is executed in x4, then downshift is only to x1 and not to x2.

**Note:** The restriction requires that a x2 interface to the I350 must connect to lanes 0 and 1 on the I350. The PCIe Card Electromechanical specification does not allow to route a x2 link to a wider connector. Therefore, a system designer is not allowed to connect a x2 link to lanes 2

and 3 of a PCIe connector. It is also recommended that when used in x2 mode on a NIC, the I350 is connected to lanes 0 and 1 of the NIC.

**Figure 3-2 Lane Reversal Supported Modes**

### 3.1.6.7 Reset

The PCIe PHY can supply core reset to the I350. The reset can be caused by two sources:

1. Upstream move to hot reset - Inband Mechanism (LTSSM).
2. Recovery failure (LTSSM returns to detect).
3. Upstream component moves to Disable.

### 3.1.6.8 Scrambler Disable

The scrambler/de-scrambler functionality in the I350 can be eliminated by the two Upstream according to the PCIe specification.

## 3.1.7 Error Events and Error Reporting

### 3.1.7.1 Mechanism in General

PCIe defines two error reporting paradigms: the baseline capability and the Advanced Error Reporting (AER) capability. The baseline error reporting capabilities are required of all PCIe devices and define the minimum error reporting requirements. The AER capability is defined for more robust error reporting and is implemented with a specific PCIe capability structure.

Both mechanisms are supported by the I350.

Also the *SERR# Enable* and the *Parity Error* bits from the legacy Command register take part in the error reporting and logging mechanism.

In a multi-Function device, PCI Express errors that are not related to any specific Function within the device, are logged in the corresponding status and logging registers of all functions in that device. These include the following cases of Unsupported Request (UR):

- A memory or I/O access that does not match any BAR for any function
- Messages.
- Configuration accesses to a non-existent function.

### 3.1.7.2 Error Events

Table 3-12 lists the error events identified by the I350 and the response in terms of logging, reporting, and actions taken. Consult the PCIe specification for the effect on the PCI Status register.

**Table 3-12 Response and Reporting of PCIe Error Events**

| Error Name                     | Error Events                                                                                                                                                      | Default Severity                             | Action                                                                                                            |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| PHY errors                     |                                                                                                                                                                   |                                              |                                                                                                                   |
| Receiver error                 | 8b/10b decode errors<br>Packet framing error                                                                                                                      | Correctable.<br>Send ERR_CORR                | TLP to initiate NAK and drop data.<br>DLLP to drop.                                                               |
| Data link errors               |                                                                                                                                                                   |                                              |                                                                                                                   |

| Completion with unsuccessful completion status |                                                                                                                                                                                                                                                                                                                      | No action (already done by originator of completion). | Free FC credits.                                                                                                                                                                                                                                                                                                                                                    |
| Byte count integrity in completion process.    | When byte count isn't compatible with the length field and the actual expected completion length. For example, length field is 10 (in Dword), actual length is 40, but the byte count field that indicates how many bytes are still expected is smaller than 40, which is not reasonable.                            | No action                                             | The I350 doesn't check for this error and accepts these packets. This may cause a completion timeout condition.                                                                                                                                                                                                                                                     |

### 3.1.7.3 Error Forwarding (TLP poisoning)

If a TLP is received with an error-forwarding trailer, the transaction can be re-sent a number of times as programmed in the GCR register. If transaction still fails the packet is dropped and is not delivered to its destination. The I350 then reacts as described in [Table 3-12](#).

The I350 does not initiate any additional master requests for that PCI function until it detects an internal software reset for associated LAN port. Software is able to access device registers after such a fault.

System logic is expected to trigger a system-level interrupt to inform the operating system of the problem. Operating systems can then stop the process associated with the transaction, re-allocate memory instead of the faulty area, etc.

### 3.1.7.4 ECRC

The I350 supports End to End CRC (ECRC) as defined in the PCIe spec. The following functionality is provided:

- Insertion of ECRC in all transmitted TLPs:
  - The I350 indicates support for insertion of ECRC in the ECRC Generation Capable bit of the PCIe configuration registers. This bit is loaded from the ECRC Generation EEPROM bit.
  - Insertion of ECRC is enabled by the ECRC Generation Enable bit of the PCIe configuration registers.
- ECRC is checked on all incoming TLPs. A packet received with an ECRC error is dropped. Note that for completions, a completion timeout will occur later (if enabled), which would result in re-issuing the request.
  - The I350 indicates support for ECRC checking in the ECRC Check Capable bit of the PCIe configuration registers. This bit is loaded from the ECRC Check EEPROM bit.
  - Checking of ECRC is enabled by the ECRC Check Enable bit of the PCIe configuration registers.
- ECRC errors are reported.
- System SW may configure ECRC independently per each LAN function.

### 3.1.7.5 Partial Read and Write Requests

#### Partial Memory Accesses

The I350 has limited support of reads and writes requests with only part of the byte enable bits set:

- Partial writes with at least one byte enabled are silently dropped.
- Zero-length writes has no internal impact (nothing written, no effect such as clear-by-write). The transaction is treated as a successful operation (no error event).
- Partial reads with at least one byte enabled are handled as a full read. Any side effect of the full read (such as clear by read) is also applicable to partial reads.
- Zero-length reads generate a completion, but the register is not accessed and undefined data is returned.

The I350 does not generate an error indication in response to any of the above events.

#### Partial I/O Accesses

- Partial access on address

- A write access is discarded
- A read access returns 0xFFFF
- Partial access on data, where the address access was correct
  - A write access is discarded
  - A read access performs the read

### 3.1.7.6 Error Pollution

Error pollution can occur if error conditions for a given transaction are not isolated on the error's first occurrence. If the Physical layer detects and reports a receiver error, to avoid having this error propagate and cause subsequent errors at upper layers the same packet is not signaled at the data link or transaction layers.

Similarly, when the data link layer detects an error, subsequent errors that occur for the same packet are not signaled at the transaction layer.

### 3.1.7.7 Completion with Unsuccessful Completion Status

A completion with unsuccessful completion status is dropped and not delivered to its destination. An interrupt is generated to indicate unsuccessful completion.

### 3.1.7.8 Error Reporting Changes

The Rev. 1.1 specification defines two changes to advanced error reporting. A new *Role-Based Error Reporting* bit in the *Device Capabilities* register is set to 1b to indicate that these changes are supported by the I350. These changes are:

1. Setting the *SERR# Enable* bit in the PCI Command register also enables UR reporting (in the same manner that the *SERR# Enable* bit enables reporting of correctable and uncorrectable errors). In other words, the *SERR# Enable* bit overrides the *UR Error Reporting Enable* bit in the PCIe Device Control register.
2. Changes in the response to some uncorrectable non-fatal errors, detected in non-posted requests to the I350. These are called advisory Non-fatal error cases. For each of the errors that follow, the following behavior is defined:
  - a. The *Advisory Non-Fatal Error Status* bit is set in the Correctable Error Status register to indicate the occurrence of the advisory error and the *Advisory Non-Fatal Error Mask* corresponding bit in the Correctable Error Mask register is checked to determine whether to proceed further with logging and signaling.
  - b. If the *Advisory Non-Fatal Error Mask* bit is clear, logging proceeds by setting the corresponding bit in the Uncorrectable Error Status register, based upon the specific uncorrectable error that's being reported as an advisory error. If the corresponding uncorrectable error bit in the Uncorrectable Error Mask register is clear, the First Error Pointer and Header Log registers are updated to log the error, assuming they are not still occupied by a previously unserved error.
  - c. An *ERR\_COR* message is sent if the *Correctable Error Reporting Enable* bit is set in the Device Control register. An *ERROR\_NONFATAL* message is not sent for this error.

The following uncorrectable non-fatal errors are considered as advisory non-fatal Errors:

- A completion with an Unsupported Request or Completer Abort (UR/CA) status that signals an uncorrectable error for a non-posted request. If the severity of the UR/CA error is non-fatal, the completer must handle this case as an advisory non-fatal error.

- When the requester of a non-posted request times out while waiting for the associated completion, the requester is permitted to attempt to recover from the error by issuing a separate subsequent request, or to signal the error without attempting recovery. The requester is permitted to attempt recovery zero, one, or multiple (finite) times, but must signal the error (if enabled) with an uncorrectable error message if no further recovery attempts are made. If the severity of the completion timeout is non-fatal and the requester elects to attempt recovery by issuing a new request, the requester must first handle the current error case as an advisory non-fatal error.
- Reception of a poisoned TLP. Refer to [Section 3.1.7.3](#).
- When a receiver receives an unexpected completion and the severity of the unexpected completion error is non-fatal, the receiver must handle this case as an advisory non-fatal error.

### 3.1.7.9 Completion with Completer Abort (CA)

A DMA master transaction ending with a Completer Abort (CA) completion causes all PCIe master transactions to stop; the *PICAUSE.ABR* bit is set and an interrupt is generated if the appropriate mask bits are set. To enable PCIe master transactions following reception of a CA completion, software issues an FLR to the right function or a PCI reset to the device and re-initializes the function(s).

**Note:** Asserting *CTRL.DEV\_RST* Flushes any pending transactions on the PCIe and reset's all ports.

## 3.1.8 PCIe Power Management

Described in [Section 5.4.1](#) - Power Management.

## 3.1.9 PCIe Programming Interface

Described in [Section 9](#) - PCIe Programming Interface

## 3.2 Management Interfaces

The I350 contains two possible interfaces to an external BMC.

- SMBus
- NC-SI

### 3.2.1 SMBus

SMBus is an optional interface for pass-through and/or configuration traffic between an external BMC and the I350. The SMBus channel behavior and the commands used to configure or read status from the I350 are described in [Section 10.5](#).

The I350 also enables reporting and controlling the device using the MCTP protocol over SMBus. The MCTP interface will be used by the BMC to only control the NIC and not for pass through traffic. All network ports are mapped to a single MCTP endpoint on SMBus. For information, refer to [Section 10.7](#).

### 3.2.1.1 Channel Behavior

The SMBus specification defines a maximum frequency of 100 KHz. However, the SMBus interface can be activated up to 400 KHz without violating any hold and setup time.

SMBus connection speed bits define the SMBus mode. Also, SMBus frequency support can be defined only from the EEPROM.

## 3.2.2 NC-SI

The NC-SI interface in the I350 is a connection to an external BMC defined by the DMTF NC-SI protocol. It operates as a single interface with an external BMC, where all traffic between the I350 and the BMC flows through the interface.

The I350 supports the standard DMTF NC-SI protocol for both pass-through and control traffic as defined in [Section 10.6](#).

### 3.2.2.1 Electrical Characteristics

The I350 complies with the electrical characteristics defined in the NC-SI specification.

The I350 NC-SI behavior is configured on power-up in the following manner:

- The I350 provides an NC-SI clock output if defined by the *NC-SI Output Clock Disable* EEPROM bit ([Section 6.2.22](#)). The default value is to use an external clock source as defined in the NC-SI specification.
- The output driver strength for the NC-SI\_CLK\_OUT pad is configured by the *NC-SI Clock Pad Drive Strength* bit (default = 0b) in the *Functions Control* EEPROM word (refer to [Section 6.2.22](#)).
- The output driver strength for the NC-SI output signals (NC-SI\_DV & NC-SI\_RX) is configured by the EEPROM *NC-SI Data Pad Drive Strength* bit (default = 0b; refer to [Section 6.2.22](#)).
- The *Multi-Drop NC-SI* EEPROM bit (refer to [Section 6.3.7.3](#)) defines the NC-SI topology (point-to-point or multi-drop; the default is multi-drop).

The I350 can provide an NC-SI clock output as previously mentioned. The NC-SI clock input (NC-SI\_CLK\_IN) serves as an NC-SI input clock in either case. That is, if the I350 provides an NC-SI output clock, the platform is required to route it back through the NC-SI clock input with the correct latency. Refer to [Chapter 11, “Electrical/Mechanical Specification”](#) for details.

The I350 dynamically drives its NC-SI output signals (NC-SI\_DV and NC-SI\_RX) as required by the sideband protocol:

- On power-up, the I350 floats the NC-SI outputs except for NCSI\_CLK\_OUT.
- If the I350 operates in point-to-point mode, then the I350 starts driving the NC-SI outputs some time following power-up.
- If the I350 operates in a multi-drop mode, the I350 drives the NC-SI outputs as configured by the BMC.

### 3.2.2.2 NC-SI Transactions

The NC-SI link supports both pass-through traffic between the BMC and the I350 LAN functions, as well as configuration traffic between the BMC and the I350 internal units as defined in the NC-SI protocol. Refer to [Section 10.6.2](#) for information.

## 3.3 Flash / EEPROM

### 3.3.1 EEPROM Interface

#### 3.3.1.1 General Overview

The I350 uses an EEPROM device for storing product configuration information. The EEPROM is divided into three general regions:

- Hardware accessed - Loaded by the I350 after power-up, PCI reset de-assertion, D3 ->D0 transition, or a software-commanded EEPROM read (*CTRL\_EXT.EE\_RST*).
- Manageability firmware accessed - Loaded by the I350 in pass-through mode after power-up or firmware reset.
- Software accessed - Used only by software. The meaning of these registers, as listed here, is a convention for software only and is ignored by the I350.

Table 3-13 lists the structure of the EEPROM image in the I350.

**Table 3-13 EEPROM Structure**

| Address       | Content                                                       |
|---------------|---------------------------------------------------------------|
| 0x0 – 0x9     | LAN 0 MAC address and software area                           |
| 0xA – 0x2F    | LAN 0 and Common hardware area                                |
| 0x30 – 0x3E   | PXE area                                                      |

The EEPROM mapping is described in [Chapter 6](#).

#### 3.3.1.2 EEPROM Device

The EEPROM interface supports an SPI interface and expects the EEPROM to be capable of 2 MHz operation.

The I350 is compatible with various sizes of 4-wire serial EEPROM devices. If pass-through mode functionality is desired, up to 256 Kbits serial SPI compatible EEPROM can be used. If no manageability mode is desired, a 128 Kbit (16 Kbyte) serial SPI compatible EEPROM can be used. All EEPROM's are accessed in 16-bit words although the EEPROM interface is designed to also accept 8-bit data accesses.

The I350 automatically determines the address size to be used with the SPI EEPROM it is connected to and sets the EEPROM address size field of the *EEPROM/FLASH Control and Data* register (*EEC.EE\_ADDR\_SIZE*) field appropriately. Software can use this size to determine how to access the EEPROM. The exact size of the EEPROM is determined within one of the EEPROM words.

**Note:** The different EEPROM sizes have two differing numbers of address bits (8 bits or 16 bits), and therefore must be accessed with a slightly different serial protocol. Software must be aware of this if it accesses the EEPROM using direct access.

### 3.3.1.3 HW Initial Load Process.

Upon power on reset or PCIe reset, the I350 reads the global device parameters from the EEPROM including all the parameters impacting the content of the PCIe configuration space. Upon a software reset to one of the ports (*CTRL.RST* set to 1), a partial load is done of the parameters relevant to the port where the software reset occurred. Upon a software reset to all ports (*CTRL.DEV\_RST* = 1) a partial load is done of the parameters relevant to all ports. [Table 3-14](#) lists the words read in each EEPROM auto-read sequence. During full load after power-on all hardware related EEPROM words are loaded. Following a software reset only a subset of the hardware related EEPROM words are loaded. For details of the content of each word - refer to [Chapter 6](#).

**Notes:**

1. LANx\_start parameter in [Table 3-14](#) relates to start of LAN related EEPROM section where:
  - LAN0\_start = 0x0
  - LAN1\_start = 0x80
  - LAN2\_start = 0xC0
  - LAN3\_start = 0x100
2. In the Dual port SKU and 25x25 package SKU EEPROM words related to ports 2 and 3 are not read during the Auto-load sequence.

**Table 3-14 EEPROM Auto-Load Sequence**

1. Upon assertion of *CTRL.DEV\_RST* by software partial load of parameters relevant to all ports is done. Assertion of *CTRL\_EXT.EE\_RST* causes load of per port parameters similar to *CTRL\_RST*.

2. Loaded only if load subsystem ID bit is set

3. Loaded only if load device ID bit is set

4. EEPROM words listed under Management Section are also loaded following Firmware Reset in addition to word 0x12 (read by HW).

### 3.3.1.4 Software Accesses

The I350 provides two different methods for software access to the EEPROM. It can either use the built-in controller to read the EEPROM or access the EEPROM directly using the EEPROM's 4-wire interface.

In addition, the VPD area of the EEPROM can be accessed via the VPD capability structure of the PCIe.

Software can use the EEPROM Read (*EERD*) register to cause the I350 to read a word from the EEPROM that the software can then use. To do this, software writes the address to read to the *Read Address* (*EERD.ADDR*) field and simultaneously writes a 1b to the *Start Read* bit (*EERD.START*). The I350 reads the word from the EEPROM, sets the *Read Done* bit (*EERD.DONE*), and places the data in the *Read Data* field (*EERD.DATA*). Software can poll the EEPROM Read register until it sees the *Read Done* bit set and then uses the data from the *Read Data* field. Any words read this way are not written to the I350's internal registers.

Software can also directly access the EEPROM's 4-wire interface through the EEPROM/Flash Control (*EEC*) register. It can use this for reads, writes, or other EEPROM operations.

To directly access the EEPROM, software should follow these steps:

1. Take ownership of the EEPROM Semaphore bit as described in [Section 4.7.1](#).
2. Write a 1b to the *EEPROM Request* bit (*EEC.EE\_REQ*).
3. Poll the *EEPROM Grant* bit (*EEC.EE\_GNT*) until it becomes 1b. It remains 0b as long as the hardware is accessing the EEPROM.
4. Write or read the EEPROM using the direct access to the 4-wire interface as defined in the EEPROM/Flash Control and Data (*EEC*) register. The exact protocol used depends on the EEPROM placed on the board and can be found in the appropriate datasheet.
5. Write a 0b to the *EEPROM Request* bit (*EEC.EE\_REQ*) to enable EEPROM access by other drivers.

**Notes:** If direct access via the EEPROM's 4-wire interface to a read protected area is attempted, the I350 blocks the access and sets the *EEC.EE\_BLOCKED* bit. To clear the block condition and enable further access to the EEPROM software should write 1b to the *EEC.EE\_CLR\_ERR* bit.

Following execution of an EEPROM write operation using direct access software should verify that the write operation has completed and EEPROM status is ready before clearing the *EEC.EE\_REQ* and *EEC.EE\_GNT* bits.

Finally, software can cause the I350 to re-read the per-function hardware accessed fields of the EEPROM (setting the I350's internal registers appropriately similar to software reset) by writing a 1b to the *EEPROM Reset* bit of the Extended Device Control register (*CTRL\_EXT.EE\_RST*).

**Note:** If the EEPROM does not contain a valid signature (refer to [Section 3.3.1.5](#)), the I350 assumes 16-bit addressing. In order to access an EEPROM that requires 8-bit addressing, software must use the direct access mode.

### 3.3.1.5 EEPROM Detection and Signature Field

The I350 supports detection of EEPROM existence following power-up and detection of a valid EEPROM image via the EEPROM signature field in the *Sizing and Protected Fields* EEPROM word (refer to [Section 6.2.9](#)).

#### 3.3.1.5.1 EEPROM Detection

The I350 will check if an EEPROM is connected following power-up by sending a get status command to the EEPROM. If the EEPROM response is correct, the I350 will set the *EEC.EE\_DET* bit to 1b. If EEPROM status received is incorrect, the I350 assumes that there is no EEPROM connected, clears the *EEC.EE\_DET* bit to 0b and works in EEPROM-less mode. The I350 will not attempt any further EEPROM auto-load operations as defined in [Section 3.3.1.3](#) if the *EEC.EE\_DET* bit is cleared to 0b after attempting an auto-load operation following power-up. Even if an EEPROM with a valid image is later connected, the I350 will not attempt an auto-read until a full power-up cycle is performed.

**Note:** When an incorrect EEPROM status is read after power-up the EEPROM is still accessible to software via the *EERD* register or by issuing bit banging operations using the *EEC* register, however EEPROM auto-load following reset as defined in [Section 3.3.1.3](#) is not executed.

#### 3.3.1.5.2 Detection of Valid EEPROM Image

Following the various resets before executing an EEPROM auto-load operation as defined in [Section 3.3.1.3](#) the I350 determines if a valid EEPROM image is present by first reading the EEPROM signature in the *Sizing and Protected Fields* EEPROM word at address 0x12. It checks the signature value in bits 15 and 14 of the EEPROM word. If bit 15 is 0b and bit 14 is 1b, it considers the EEPROM image valid, the *EEC.EE\_PRES* bit is set to 1 to indicate that a valid signature was detected and

additional EEPROM words are read to program its internal registers as defined in [Section 3.3.1.3](#). Otherwise, it ignores the value read from the *EEPROM Sizing and Protected Fields* word at address 0x12, clears the *EEC.EE\_PRE* bit to 0 and does not read any other words as part of the auto-load process.

**Note:** Following the various resets the I350 executes an EEPROM auto-load operation as defined in [Section 3.3.1.3](#) if bit 15 in the *EEPROM Sizing and Protected Fields* word is read as 1b or bit 14 is read as 0b, the I350 assumes that the EEPROM image is not valid and does not continue the auto-load process. If a valid image is later programmed, the I350 will attempt to do an auto-load operation following the various reset assertions and set the *EEC.EE\_PRE* bit is set to 1 if a valid signature is read.

### 3.3.1.6 Protected EEPROM Space

The I350 provides a mechanism for a hidden area in the EEPROM to the host. The hidden area cannot be accessed (read or written to) via the EEPROM registers in the CSR space. It can be accessed only by the manageability subsystem. This area is located at the end of the EEPROM memory. its size is defined by the *HEPSize* field in EEPROM word 0x12.

**Note:** Current I350 manageability firmware does not use any hidden area protected by the *HEPSize* mechanism.

A mechanism to protect part of the EEPROM from host writes and the VPD area from host writes is also provided. This mechanism is controlled by words 0x2D and 0x2C that define the start and the end of the read-only area and bit 4 (enable protection) of EEPROM word 0x12 that enables the mechanism.

#### 3.3.1.6.1 Initial EEPROM Programming

In most applications, initial EEPROM programming is done directly on the EEPROM pins. Nevertheless, it is desired to enable existing software utilities (accessing the EEPROM via the host interface) to initially program the entire EEPROM without breaking the protection mechanism. Following a power-up sequence, the I350 reads the hardware initialization words in the EEPROM. If the signature in word 0x12 does not equal 01b, the EEPROM is assumed as non-programmed. There are two outcomes of a non-valid signature:

- The I350 does not read any further EEPROM data and sets the relevant registers to default.
- The I350 enables access to any location in the EEPROM via the EEPROM *EERD* and *ECC* registers.

#### 3.3.1.6.2 Activating the Protection Mechanism

Following initialization, the I350 reads the EEPROM and turns on the protection mechanism if word 0x12 contains a valid signature (equals 01b) and bit 4 (enable protection) of word 0x12 is set. Once the protection mechanism is turned on, words 0x12, 0x2C, 0x2D and 0x2F (VPD pointer) become write-protected, the area that is defined by word 0x12 becomes hidden (read/write protected) and the area defined by words 0x2C and 0x2D and the VPD area becomes write protected.

- No matter what is designated as the read only protected area, words 0x30:0x3F (used by PXE driver) are writable, unless the area is defined as hidden or is part of the VPD area.

#### 3.3.1.6.3 Non Permitted Accessing to Protected Areas in the EEPROM

This paragraph refers to EEPROM accesses via the EEC (bit banging) or EERD (parallel read access) registers. Following a write access to the protected areas in the EEPROM, hardware responds properly on the PCIe interface but does not initiate any access to the EEPROM. Following a read access to the hidden area in the EEPROM (as defined by word 0x12), hardware does not access the EEPROM and returns meaningless data to the host.

**Note:** Using bit banging, the SPI EEPROM can be accessed in a burst mode. For example, providing op-code, address, and then read or write data for multiple bytes. Hardware inhibits any attempt to access the protected EEPROM locations even in burst accesses.

Software should not access the EEPROM in a burst-write mode starting in a non-protected area and continue to a protected one. In such a case it is not guaranteed that the write access to any area ever takes place.

### 3.3.1.7 EEPROM Recovery

The EEPROM contains fields that if programmed incorrectly might affect the functionality of the I350. The impact can range from an incorrect setting of some function (such as LED programming), via disabling of entire features (such as no manageability) and link disconnection, to the inability to access the I350 via the regular PCIe interface.

The I350 implements a mechanism that enables recovery from a faulty EEPROM no matter what the impact is, using an SMBus message that instructs firmware to invalidate the EEPROM.

This mechanism uses a SMBus message that the firmware is able to receive in all modes when a EEPROM with a valid signature is detected, no matter what the content of the EEPROM is (even in diagnostic mode). After receiving this kind of message, firmware clears EEPROM in word 0x12 together with the signature (bits 15/14 to 00b). Afterwards, the BIOS/operating system initiates a reset to force an EEPROM auto-load process that fails in order to enable access to the I350. At this stage software can now re-program the EEPROM using the EEC register (refer to [Section 3.3.1.4](#)).

Firmware is programmed to receive such a command only from a PCIe reset until one of the functions changes its status from D0u to D0a. Once one of the functions moves to D0a, it can be safely assumed that the I350 is accessible to the host and there is no further need for this function. This reduces the possibility of malicious software using this command as a back door and limits the time firmware must be active in non-manageability mode.

The command is sent on a fixed SMBus address of 0xC8. The format of the command is the SMBus Block write as follows:

**Table 3-15 Command Format**

| Function       | Command | Byte Count | Data Byte |
|----------------|---------|------------|-----------|
| Release EEPROM | 0xC7    | 0x01       | 0xAA      |

**Notes:**

1. This solution requires a controllable SMBus connection to the I350.
2. If more than one I350 part is in a state to accept this command, all of the devices in this state will respond with an ACK to this command and accept it. A device with one of its ports in D0a should not respond with an ACK to this command if not in D0u state.
3. The I350 is guaranteed to accept the command on the SMBus interface and on address 0xC8. If one of the functions is not in D0u state, the I350 will not accept the command and will return a NACK. If the firmware has a station address, it may answer on this address also. If the SMBus address is

different from 0xC8 or the station address, then the I350 disregards the command but an ACK is returned.

4. When one of the functions is not in D0u state the NACK is sent at end of the command. A ACK is always returned after the address.
5. After receiving a release EEPROM command, firmware should keep its current state. It is the responsibility of the programmer that is updating the EEPROM to send a firmware reset (if required) after the full EEPROM update process completes.

### 3.3.1.8 EEPROM-Less Support

The I350 supports EEPROM-less operation with the following limitations:

- Non-manageability mode only.
- No support for legacy Wake on LAN (magic packets).
- No support for Flash storage of option ROM code (such as PXE) on a NIC.
- No legacy option ROM support (PXE, iSCSI Boot, etc.) is available on NIC or LOM.
- No support for serial ID PCIe capability.
- The EEPROM images released by Intel contains a set of configuration defaults overrides. All initialization values usually taken from the EEPROM should be done by the host driver.

#### 3.3.1.8.1 Access to the EEPROM Controlled Feature

The *EEARBC* register (refer to [Section 8.4.5](#)) enables access to registers that are not accessible via regular CSR access (such as PCIe configuration read-only registers) by emulating the auto-read process. *EEARBC* contains six strobe fields that emulate the internal strobes of the internal auto-read process. This register is common to all functions and should be accessed only after verifying that it's not being accessed by other functions.

Writing to one of the EEPROM words is executed in two steps:

1. Write 0x0 to the *EEARBC* register.
2. Program the *EEARBC* register with the EEPROM address (*EEARBC.ADDR*), Data to be written (*EEARBC.DATA*) and set the relevant Strobe bits (*EEARBC.VALID\_\**) as defined in [Table 3-16](#).

[Table 3-16](#) lists the strobe to be used when emulating a read of a specific word of the EEPROM auto-read feature.

**Table 3-16 Strokes for EEARBC Auto-Read Emulation**

| EEPROM Word Emulated (In Hex) | Content                      | Port 0 Strobe | Port 1 Strobe | Port 2 Strobe | Port 3 Strobe |
|-------------------------------|------------------------------|---------------|---------------|---------------|---------------|
| 0:2                           | MAC address                  | VALID_CORE0   | N/A           | N/A           | N/A           |
| LAN1_start + 0:2              |                              | N/A           | VALID_CORE1   | N/A           | N/A           |

1. If word 0xA was accessed before the subsystem or subvendor ID are set, care must be taken that the load Subsystem IDs bit in word 0xA is set.
2. If word 0xA was accessed before one of the device IDs is set, care must be taken that the load Device IDs bit in word 0xA is set.
3. For the write of EEPROM word 0x15 to take effect a software reset needs to be issued following the write.
4. Part of the parameters that can be configured through the EEARBC register can be directly set through regular registers and thus usage of this mechanism is not needed for them. Specifically, words 0x1C, 0x1F and 0x2E control parameters that can be set through regular registers.
5. In EEPROM-less mode VPD is not supported.

## 3.3.2 Shared EEPROM

The I350 uses a single EEPROM device to configure hardware default parameters for all LAN devices, including Ethernet Individual Addresses (IA), LED behaviors, receive packet filters for manageability, wake-up capability, etc. Certain EEPROM words are used to specify hardware parameters that are LAN device-independent (such as those that affect circuit behavior). Other EEPROM words are associated with a specific LAN device. All LAN devices access the EEPROM to obtain their respective configuration settings.

### 3.3.2.1 EEPROM Deadlock Avoidance

The EEPROM is a shared resource between the following clients:

- Hardware auto-read.
- Port 0 LAN driver accesses.
- Port 1 LAN driver accesses.
- Port 2 LAN driver accesses.

- Port 3 LAN driver accesses.
- Firmware accesses.

All clients can access the EEPROM using parallel access, where hardware implements the actual access to the EEPROM. Hardware can schedule these accesses so that all clients get served without starvation.

However, software and hardware clients can access the EEPROM using bit banging. In this case, there is a request/grant mechanism that locks the EEPROM to the exclusive usage of one client. If this client is stuck (without releasing the lock), the other clients are not able to access the EEPROM. In order to avoid this, the I350 implements a timeout mechanism, which releases ownership of a client that didn't toggle the EEPROM bit-bang interface for more than two seconds. When the timeout mechanism is activated the *EEC.EE\_REQ* and *EEC.EE\_GNT* bits of the offending port are cleared. To initiate a new bit banging access SW will need to re-assert the *EEC.EE\_REQ* bit. The EEPROM deadlock avoidance mechanism is enabled when the *Deadlock Timeout Enable* bit in the *Initialization Control Word 1* EEPROM word is set to 1.

**Note:** If an agent that was granted access to the EEPROM for bit-bang access didn't toggle the bit bang interface for 500 ms, it should check if it still owns the interface and is not blocked before continuing the bit-banging.

When Hardware EEPROM bit-bang access is aborted due to Deadlock avoidance or management reset the *EEC.EE\_ABORT* bit is set. To clear the block condition and enable further access to the EEPROM, software should write 1b to the *EEC.EE\_CLR\_ERR* bit.

### 3.3.2.2 EEPROM Map Shared Words

The EEPROM map in [Section 6.1](#) identifies those words configuring either LAN devices or the entire I350 component as “all”. Those words configuring a specific LAN device parameter are identified by their LAN number.

The following EEPROM words warrant additional notes specifically related to quad-LAN support:

**Table 3-17 Notes on EEPROM Words**

|                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Initialization Control 1,<br>(shared between LANs)                                                        | This EEPROM word specifies hardware-default values for parameters that apply a single value to all LAN devices, such as link configuration parameters required for auto-negotiation, wake-up settings, PCIe bus advertised capabilities, etc.                                                                                                                                           |
| Initialization Control 2<br>Initialization Control 3,<br>Initialization Control 4<br>(unique to each LAN) | These EEPROM words configure default values associated with each LAN device's hardware connections, including which link mode (internal PHY, SGMII, SerDes, 1000BASE-BX, 1000BASE-KX) is used with this LAN device. Because a separate EEPROM word configures the defaults for each LAN, extra care must be taken to ensure that the EEPROM image does not specify a resource conflict. |

### 3.3.3 Vital Product Data (VPD) Support

The EEPROM image might contain an area for VPD. This area is managed by the OEM vendor and doesn't influence the behavior of hardware. Word 0x2F of the EEPROM image contains a pointer to the VPD area in the EEPROM. A value of 0xFFFF means VPD is not supported and the VPD capability doesn't appear in the configuration space.

The maximum area size is 256 bytes but can be smaller. The VPD block is built from a list of resources. A resource can be either large or small. The structure of these resources is listed in the following tables.

**Table 3-18 Small Resource Structure**

|                |                                                                           |       |
|----------------|---------------------------------------------------------------------------|-------|
| <b>Offset</b>  | 0                                                                         | 1 - n |
| <b>Content</b> | Tag = 0xxx, yyyyb (Type = Small(0), Item Name = xxxx, length = yyy bytes) | Data  |

**Table 3-19 Large Resource Structure**

|                |                                                          |        |       |
|----------------|----------------------------------------------------------|--------|-------|
| <b>Offset</b>  | 0                                                        | 1 - 2  | 3 - n |
| <b>Content</b> | Tag = 1xxx, xxxxb (Type = Large(1), Item Name = xxxxxxx) | Length | Data  |

The I350 parses the VPD structure during the auto-load process (power up and PCIe reset or warm reset) in order to detect the read-only and read/write area boundaries. The I350 assumes the following VPD structure:

**Table 3-20 VPD Structure**

| Tag  | Structure Type | Length (Bytes)              | Data       | Resource Description                                                                        |
|------|----------------|-----------------------------|------------|---------------------------------------------------------------------------------------------|
| 0x82 | Large          | Length of identifier string | Identifier | Identifier string.                                                                          |
| 0x90 | Large          | Length of RO area           | RO data    | VPD-R list containing one or more VPD keywords. This part is optional and might not appear. |
| 0x91 | Large          | Length of R/W area          | RW data    | VPD-W list containing one or more VPD keywords. This part is optional and might not appear. |
| 0x78 | Small          | N/A                         | N/A        | End tag.                                                                                    |

**Note:** The VPD-R and VPD-W structures can be in any order.

If the I350 doesn't detect a value of 0x82 in the first byte of the VPD area, or the structure doesn't follow the description listed in [Table 3-20](#), it assumes the area is not programmed and the entire 256 bytes area is read only. If a VPD-W tag is found after the VPD-R tag, the area defined by its size is writable via the VPD structure. Refer to the PCI 3.0 specification (Appendix I) for details of the different tags.

In any case, the VPD area is accessible for read and write via the regular EEPROM mechanisms pending the EEPROM protection capabilities enabled. For example, if VPD is in the protected area, the VPD area is not accessible to the software device driver (parallel or serial), but accessible through the VPD mechanism. If the VPD area is not in the protected area, then the software device driver can access all of it for read and write.

The VPD area can be accessed through the PCIe configuration space VPD capability structure described in [Section 9.5.5](#). Write accesses to a read-only area or any access outside of the VPD area via this structure are ignored.

**Note:** Write access to Dwords, which are only partially in the read/write area, are ignored. It is responsibility of VPD software to make the right alignment to enable a write to the entire area.

## 3.3.4 Flash Interface

### 3.3.4.1 Flash Interface Operation

The I350 provides two different methods for software access to the Flash.

Using the legacy Flash transactions, the Flash is read from or written to each time the host CPU performs a read or a write operation to a memory location that is within the Flash address mapping or after a re-boot via accesses in the space indicated by the Expansion ROM Base Address register. All accesses to the Flash require the appropriate command sequence for the device used. Refer to the specific Flash data sheet for more details on reading from or writing to Flash. Accesses to the Flash are based on a direct decode of CPU accesses to a memory window defined in either:

1. The I350's Flash Base Address register (PCIe Control register at offset 0x10 and 0x14. Refer to [Section 9.4.11](#)).
2. The Expansion ROM Base Address register (PCIe Control register at offset 0x30. Refer to [Section 9.4.15](#)).

The I350 controls accesses to the Flash when it decodes a valid access.

#### Notes:

1. Flash read accesses are assembled by the I350 each time the read access is greater than a byte-wide access.
2. Flash read access times is in the order of 2  $\mu$ s (Depending on Flash specification).
3. Flash write access times can be in the order of 2  $\mu$ s to 200  $\mu$ s (Depending on Flash specification). Following a write access to the Flash Software should avoid initiating any read or write access to the device until the Flash write access completed.
4. The I350 supports only byte writes to the Flash.

Another way for software to access the Flash is directly using the Flash's 4-wire interface through the Flash Access (*FLA*) register. It can use this for reads, writes, or other Flash operations (accessing the Flash status register, erase, etc.).

To directly access the Flash, software should follow these steps:

1. Take ownership of the Flash Semaphore bit as described in [Section 4.7.1](#).
2. Write a 1b to the *Flash Request* bit (*FLA.FL\_REQ*).
3. Read the *Flash Grant* bit (*FLA.FL\_GNT*) until it becomes 1b. It remains 0b as long as there are other accesses to the Flash.
4. Write or read the Flash using the direct access to the 4-wire interface as defined in the *FLA* register. The exact protocol used depends on the Flash placed on the board and can be found in the appropriate datasheet.
5. Write a 0b to the *Flash Request* bit (*FLA.FL\_REQ*).

**Note:** When Hardware Flash bit-bang access is aborted due to Deadlock avoidance the *FLA.FLA\_ABORT* bit is set. To clear the block condition and enable further access to the Flash, software should write 1b to the *FLA.FLA\_CLR\_ERR* bit.

### 3.3.4.2 Flash Write Control

The Flash is write controlled by the *FWE* bits in the *EEPROM/FLASH Control and Data (EEC)* register.

After sending one byte write to the Flash, software should wait 2  $\mu$ s to 200  $\mu$ s (Depending on Flash specification) for the write access to complete before initiating the next Flash byte write access or before accessing any other register.

### 3.3.4.3 Flash Erase Control

When software needs to erase the Flash, it should set bit *FLA.FL\_ER* in the *FLA* register to 1b (Flash erase) and then set bits *EEC.FWE* in the *EEPROM/Flash Control* register to 0b.

Hardware gets this command and sends the Erase command to the Flash. The erase process finishes by itself. Software should wait for the end of the erase process before any further access to the Flash. This can be checked by using the Flash write control mechanism previously described in [Section 3.3.4.2](#).

The op-code used for erase operation is defined in the *FLASHOP* register.

**Note:** Sector erase by software is not supported. In order to delete a sector, the serial (bit bang) interface should be used.

## 3.3.5 Shared FLASH

The I350 provides an interface to an external serial Flash/ROM memory device, as described in [Section 2.3.2](#). This Flash/ROM device can be mapped into memory and/or IO address space for each LAN device through the use of Base Address Registers (BARs).

Clearing the *Flash Size* and *CSR\_Size* fields in *PCIe Control 2* EEPROM word (Word 0x28) to 0, disables Flash mapping to PCI space of all LAN ports via the *Flash Base Address* register. Setting the *LAN Boot Disable* bit in the per LAN port *Initialization Control 3* EEPROM word, disables Flash mapping to PCI space for LAN 0, LAN1, LAN2 and LAN 3 respectively, via the *Expansion ROM Base Address* register.

### 3.3.5.1 Flash Access Contention

The I350 implements internal arbitration between Flash accesses initiated from the LAN 0, LAN 1, LAN 2 and LAN 3 devices. If accesses from these LAN devices are initiated during the same window, The first one is served first and only then the following devices are served in a Round Robin fashion.

**Note:** The I350 does not synchronize between the entities accessing the Flash. Contentions caused by one entity reading and the other modifying the same location is possible.

To avoid this contention, accesses from the LAN devices should be synchronized using external software synchronization of the memory or I/O transactions responsible for the access. It might be possible to ensure contention-avoidance by the nature of the software sequence.

### 3.3.5.2 Flash Deadlock Avoidance

The Flash is a shared resource between the following clients:

- Port 0 LAN driver accesses.
- Port 1 LAN driver accesses.
- Port 2 LAN driver accesses.
- Port 3 LAN driver accesses.

- BIOS parallel access via expansion ROM mechanism.
- Firmware accesses.

All clients can access the flash using parallel access, where hardware implements the actual access to the Flash. Hardware can schedule these accesses so that all the clients get served without starvation.

However, the driver and firmware clients can access the serial Flash using bit banging. In this case, there is a request/grant mechanism that locks the serial Flash to the exclusive usage of one client. If this client is stuck without releasing the lock, the other clients are unable to access the Flash. In order to avoid this, the I350 implements a time-out mechanism that releases the grant from a client that doesn't toggle the Flash bit-bang interface for more than two seconds.

**Note:** If an agent that was granted access to the Flash for bit-bang access doesn't toggle the bit-bang interface for 5 Seconds, it should check that it still owns the interface and is not blocked before continuing the bit banging.

**Note:** When Hardware Flash bit-bang access is aborted due to Deadlock avoidance or management reset the *FLA.FLA\_ABORT* bit is set.

This mode is enabled by bit five in word 0xA of the EEPROM.

## 3.4 Configurable I/O Pins

### 3.4.1 General-Purpose I/O (Software-Definable Pins)

The I350 has four software-defined pins (SDP pins) per port that can be used for miscellaneous hardware or software-controllable purposes. These pins and their function are bound to a specific LAN device. For example, eight SDP pins cannot be associated with a single LAN device. These pins can each be individually configurable to act as either input or output pins. The default direction of each of the four pins is configurable via the EEPROM as well as the default value of any pins configured as outputs. To avoid signal contention, all four pins are set as input pins until after the EEPROM configuration has been loaded.

In addition to all four pins being individually configurable as inputs or outputs, they can be configured for use as General-Purpose Interrupt (GPI) inputs. To act as GPI pins, the desired pins must be configured as inputs. A separate GPI interrupt-detection enable is then used to enable rising-edge detection of the input pin (rising-edge detection occurs by comparing values sampled at the internal clock rate as opposed to an edge-detection circuit). When detected, a corresponding GPI interrupt is indicated in the Interrupt Cause register.

The use, direction, and values of SDP pins are controlled and accessed using fields in the Device Control (*CTRL*) register and Extended Device Control (*CTRL\_EXT*) register.

The SDPs can be used for special purpose mechanisms such as watch dog indication (refer to [Section 3.4.2](#) for details), IEEE 1588 support (refer to [Section 7.9.4](#) for details).

### 3.4.1.1 SDP usage for SFP connectivity

When an SFP module is connected to the SerDes interface, some of the SFP signals may be connected to SDPs. The following table describes a possible connection as used in Intel's Customer Reference boards.

**Table 3-21 SDP connection for SFP boards.**

| SDP # | Usage                                | Direction | Default   |
|-------|--------------------------------------|-----------|-----------|
| 0     | Module Detect - MOD_ABS (SFP pin #6) | Input     |           |
| 1     | Tx Disable (SFP pin #3)              | Output    | Tx Enable |
| 2     | Tx Fault (SFP pin #2)                | Input     |           |
| 3     | Power on                             | Output    | Power off |

## 3.4.2 Software Watchdog

In some situations it might be useful to give an indication to manageability firmware or to external devices that the I350 hardware or the software device driver is not functional. For example, in a pass-through NIC, the I350 might be bypassed if it is not functional. In order to provide this functionality, a watchdog mechanism is used. This mechanism can be enabled by default, according to EEPROM configuration.

Once the host driver is up and it determines that hardware is functional, it might reset the watchdog timer to indicate that the I350 is functional. The software device driver should then re-arm the timer periodically. If the timer is not re-armed after pre-programmed timeout, an interrupt is sent to firmware and a pre-programmed SDPx\_0 pin (either SDP0\_0, SDP1\_0, SDP2\_0 or SDP3\_0) is asserted. Note that the SDP indication is shared between the ports. Additionally the *ICR.Software WD* bit can be set to give an interrupt to the driver when the timeout is reached.

The SDPx\_0 pin on which the watchdog timeout is indicated, is defined via the *CTRL.SDP0\_WDE* bit on the relevant port. In this mode, the *CTRL.SDP0\_IODIR* should be set to output. The *CTRL.SDP0\_DATA* bit indicates the polarity of the indication. Setting the *CTRL.SDP0\_WDE* bit in one of the ports causes the watchdog timeout indication of all ports to be routed to this SDPx\_0 pin.

The register controlling the watchdog timeout feature is the *WDSTP* register. This register enables defining a time-out period and the activation of this mode. Default watchdog timeout activation and timeout period can be set in the EEPROM.

The timer is re-armed by setting the *WDSWSTS.Dev\_functional* bit.

If software needs to trigger the watchdog immediately because it suspects hardware is stuck, it can set the *WDSWSTS.Force\_WD* bit. It can also supply firmware the cause for the watchdog, by placing additional information in the *WDSWSTS.Stuck Reason* field.

**Note:** The watchdog circuitry has no logic to detect if hardware is not functional. If the hardware is not functional, the watchdog may expire due to software not being able to access the hardware, thus indicating there is potential hardware problem.

### 3.4.2.1 Watchdog Rearm

After a watchdog indication was received, in order to rearm the mechanism the following flow should be used:

1. Clear *WD\_enable* bit in the *WDSTP* register.
2. Clear *SDP0\_WDE* bit in *CTRL* register.
3. Set *SDP0\_WDE* bit in *CTRL* register.
4. Set *WD\_enable* bit in the *WDSTP* register.

### 3.4.3 LEDs

The I350 provides four LEDs per port that can be used to indicate different statuses of the traffic. The default setup of the LEDs is done via EEPROM word offsets 0x1C and 0x1F from start of relevant LAN port section (LAN port 0, 1, 2 and 3). This setup is reflected in the *LEDCTL* register of each port. Each software device driver can change its setup individually. For each of the LEDs, the following parameters can be defined:

- Mode: Defines which information is reflected by this LED. The encoding is described in the *LEDCTL* register.
- Polarity: Defines the polarity of the LED.
- Blink mode: Determines whether or not the LED should blink or be stable.

In addition, the blink rate of all LEDs can be defined. The possible rates are 200 ms or 83 ms for each phase. There is one rate for all the LEDs of a port.

## 3.5 Voltage Regulators

The I350 operates from 3 power rails 1.0V, 1.8V and 3.3V. By using the internal 1.8V LVR (Linear Voltage Regulator) control circuit and the internal 1.0V SVR (Switched Voltage Regulator) control circuit with external low cost power transistors and LC circuitry, the I350 can be configured to operate from a single 3.3V power rail.

**Note:** To activate the 1.0V SVR control circuit and 1.8V LVR control circuitry, the VR\_EN pin should be driven high (refer to [Section 2.2.9](#)).

### 3.5.1 1.8V LVR Control

The I350 includes an on-chip Linear Voltage regulator (LVR) control circuit. Together with an external low cost BJT transistor, the circuit can be used to generate a 1.8V power supply without need for a higher cost on-board 1.8V voltage regulator. See [Figure 3-3](#).

**Figure 3-3 1.8V LVR Connection**

### 3.5.2 1.0V SVR Control

The I350 includes an on-chip Switched Voltage Regulator (SVR) control circuit. Together with external matched P/N MOS power transistors, resistors and a LC filter the SVR can be used to generate a 1.0V power supply without need for a higher cost on-board 1.0V Switched Voltage Regulator. See [Figure 3-4](#).

**Figure 3-4 1.0V SVR Connection**

## 3.6 Thermal Sensor

Using the on die Thermal Sensor, the I350 can be programmed to execute certain actions to mitigate a thermal event once device temperature passed one of 3 thermal trip points:

- Assert a SDP pin.
- Send an interrupt to the Host.
- Issue an Alert to the external BMC.
- Reduce link speed (thermal throttling).
- Power down device.

In addition, the I350 can be programmed to accept an input from a SDP pin as an indication to execute one of the above actions.

## 3.6.1 Initializing Thermal Sensor

The BMC or the EEPROM can program up to 3 thermal trip points and define thermal policies or thermal correction actions to be executed once on-die temperature exceeds pre-defined thresholds, via the *THLOWTC*, *THMIDTC* and *THHIGHTC* registers.

In addition, a hysteresis value can be defined in each of the registers to allow the thermal correction action to continue once trip point is triggered until on-die temperature is below the Threshold minus the Hysteresis value. Hysteresis provides a small amount of positive feedback to the thermal sensor circuit to prevent a trip point from flipping back and forth rapidly when the temperature is right at the trip point.

Once on-die temperature exceeds the value programmed in the *Threshold* field of the *THLOWTC*, *THMIDTC* or *THHIGHTC* Thermal Control registers; the following thermal correction actions can be taken:

- A SDP pin is asserted if the *THSDP\_OUT* bit is set to 1b in the relevant Thermal Control register. The SDP pin set and its polarity is defined in the *THACNFG* register.
- An interrupt is sent to the Host by asserting the *ICR.THS* bit if the *HINTR Thres* bit is set in the relevant Thermal Control register.
- An interrupt is sent to the Host by asserting the *ICR.THS* bit if the on-die temperature passed the trip point value defined in the *Threshold* field and then as a result of a thermal correction action went below the *Threshold - Hysteresis* value. This functionality is enabled by setting the *HINTR Hyst* bit in the relevant Thermal Control register.
- If device is in D3, a wake-up event is generated when relevant Thermal Control register generates a Thermal Sensor interrupt and the *Wake\_TH* bit is set in the register. Wake-up is initiated only if the *WUFC.THS\_WK* bit is set.
- An alert is sent to the BMC if the *BMCAL Thres* bit is set in the relevant Thermal Control register.
- An alert is sent to the BMC if the on-die temperature passed the trip point value defined in the *Threshold* field and then as a result of a thermal correction action went below the *Threshold - Hysteresis* value. This functionality is enabled by setting the *BMCAL Hyst* bit in the relevant Thermal Control register.
- Link rate of all active ports configured to internal copper PHY (*CTRL\_EXT.Link\_Mode* = 00b) can be reduced according to the link rate defined in the *TTHROTTLE* field in the relevant Thermal Control register.
- Device can be placed in thermal power down state if the *PWR\_DN* bit of the relevant Thermal Control register is set.
  - This action should be executed at a temperature which the chip must be shut down immediately. It therefore must correspond to a temperature guaranteed to be functional. Such a trip point is the last measure to prevent permanent damage to the device. On triggering the trip point, the I350 enters thermal power-down.
  - In thermal power down state:  
The following functionality is kept:
    - The PCIe interface is kept on.
    - Host can access the thermal sensor registers to identify the thermal state.
 The BMC can access the thermal sensor registers to identify the thermal state.  
The following functionality is disabled:
    - Network interfaces are down in low power state.

A thermal correction event can also be triggered by an external circuit by asserting a SDP pin if the *THSDP\_IN* bit in the *THLOWTC*, *THMIDTC* or *THHIGHTC* Thermal Control registers is set. The SDP pin used for triggering the event and its polarity can be defined in the *THACNFG* register.

The BMC or Host can read the on-die temperature and status of the Thermal Sensor circuitry by reading the *THMJT* register and the *THSTAT* register respectively.

A thermal trip point should be reached infrequently. If appropriate thermal action correction is taken, device power can be decreased before the maximum junction temperature reaches  $T_j$  (max).

Setting the trip point should take into account inaccuracies in measuring the maximum junction temperature:

- Since the thermal sensor is not necessarily located at the hottest position on-die, the trip point value is reduced by the difference in temperature between the location of the thermal sensor and the hottest place on the die.
- Since temperature measurement carries some error, the trip point value is reduced by the size of this error.

**Note:** The Thermal sensor registers are common to all functions. Before accessing any of the registers defined in this section, firmware or software should take ownership of thermal sensor semaphore bits (SW\_FW\_SYNC.SW\_PWRTS\_SM for software and SW\_FW\_SYNC.FW\_PWRTS\_SM for firmware) according to the flow defined in [Section 4.7.1](#) and release ownership of the Thermal sensor semaphore bits according to the flow defined in [Section 4.7.2](#).

## 3.6.2 Firmware Based Thermal Management

The I350 can be programmed via the BMC on the NC-SI or SMBus interfaces to initiate Thermal actions and report thermal occurrences.

## 3.6.3 Thermal Sensor Diagnostics

To enable testing thermal sensor related logic and code without need to vary the temperature, the I350 enables forcing the Thermal Sensor temperature output by setting the *THDIAG.TS Bypass* bit to 1b and specifying the required temperature indication in the *THDIAG.Tj Force field*. The forced temperature can be read in the *THMJT.Tj* field similar to the behavior in non-forced mode.

## 3.6.4 Thermal Sensor Characteristics

Table 3-22 summarizes the Thermal Sensor Characteristics.

**Table 3-22 Thermal Sensor Characteristics**

| Parameter               | Min. | Nom.    | Max. | Units | Comments/Conditions                       |
|-------------------------|------|---------|------|-------|-------------------------------------------|
| DC power supply Voltage | 0.95 | 1.0     | 1.05 | V     | +/-5%                                     |
| Data Conversion Time    |      | 13.1    |      | mS    |                                           |
| Resolution              |      | 0.25    |      | °C    | Minimum temperature that can be resolved. |
| Absolute accuracy       |      | +/-5 °C |      | °C    | Quadratic equation.                       |
| Power Supply rejection  |      | 3 °C/V  |      | °C/V  |                                           |

## 3.7 Network Interfaces

### 3.7.1 Overview

The I350 MAC provides a complete CSMA/CD function supporting IEEE 802.3 (10 Mb/s), 802.3u (100 Mb/s), 802.3z and 802.3ab (1000 Mb/s) implementations. The I350 performs all of the functions required for transmission, reception, and collision handling called out in the standards.

Each I350 MAC can be configured to use a different media interface. The I350 supports the following potential configurations:

- Internal copper PHY.
- External SerDes device such as an optical SerDes (SFP or on board) or backplane (1000BASE-BX or 1000BASE-KX) connections.
- External SGMII device. This mode is used for connections to external 10/100/1000 BASE-T PHYs that support the SGMII MAC/PHY interface.

Selection between the various configurations is programmable via each MAC's Extended Device Control register (*CTRL\_EXT.LINK\_MODE* bits) and default is set via EEPROM settings. [Table 3-23](#) lists the encoding on the *LINK\_MODE* field for each of the modes.

**Table 3-23 Link Mode Encoding**

| Link Mode | I350 Mode          |
|-----------|--------------------|
| 00b       | Internal PHY       |
| 01b       | 1000BASE-KX        |
| 10b       | SGMII              |
| 11b       | SerDes/1000BASE-BX |

The GMII/MII interface, used to communicate between the MAC and the internal PHY or the SGMII PCS, supports 10/100/1000 Mb/s operation, with both half- and full-duplex operation at 10/100 Mb/s, and only full-duplex operation at 1000 Mb/s.

The SerDes function can be used to implement a fiber-optics-based solution or backplane connection without requiring an external TBI mode transceiver/SerDes.

The SerDes interface can be used to connect to SFP modules. As such, this SerDes interface has the following limitations:

- No Tx clock
- AC coupling only

The internal copper PHY supports 10/100/1000BASE-T signaling and is capable of performing intelligent power-management based on both the system power-state and LAN energy-detection (detection of unplugged cables). Power management includes the ability to shut-down to an extremely low (powered-down) state when not needed, as well as the ability to auto-negotiate to lower-speed (and less power-hungry) 10/100 Mb/s operation when the system is in low power-states.

## 3.7.2 MAC Functionality

### 3.7.2.1 Internal GMII/MII Interface

The I350's MAC and PHY/PCS communicate through an internal GMII/MII interface that can be configured for either 1000 Mb/s operation (GMII) or 10/100 Mb/s (MII) mode of operation. For proper network operation, both the MAC and PHY must be properly configured (either explicitly via software or via hardware auto-negotiation) to identical speed and duplex settings.

All MAC configuration is performed using Device Control registers mapped into system memory or I/O space; an internal MDIO/MDC interface, accessible via software, is used to configure the Internal PHY. In addition an external MDIO/MDC interface is available to configure external PHY's that are connected to the I350 via the SGMII interface.

### 3.7.2.2 MDIO/MDC PHY Management Interface

The I350 implements an IEEE 802.3 MII Management Interface (also known as the Management Data Input/Output or MDIO Interface) between the MAC and a PHY. This interface provides the MAC and software the ability to monitor and control the state of the PHY. The MDIO interface defines a physical connection, a special protocol that runs across the connection, and an internal set of addressable registers. The interface consists of a data line (MDIO) and clock line (MDC), which are accessible by software via the MAC register space.

- MDC (management data clock): This signal is used by the PHY as a clock timing reference for information transfer on the MDIO signal. The MDC is not required to be a continuous signal and can be frozen when no management data is transferred. The MDC signal has a maximum operating frequency of 2.5 MHz.
- MDIO (management data I/O): This bi-directional signal between the MAC and PHY is used to transfer control and status information to and from the PHY (to read and write the PHY management registers).

Software can use MDIO accesses to read or write registers of the internal PHY or an external SGMII PHY, by accessing the I350's *MDIC* register (refer to [Section 8.2.4](#)). MDIO configuration setup (Internal/ External PHY, PHY Address and Shared MDIO) is defined in the *MDICNFG* register (refer to [Section 8.2.5](#)).

When working in SGMII/SerDes mode, the external PHY (if it exists) can be accessed either through MDC/MDIO as previously described, or via a two wire I<sup>2</sup>C interface bus using the *I2CCMD* register (refer to [Section 8.17.8](#)). The two wire I<sup>2</sup>C interface bus or the MDC/MDIO bus are connected via the same pins, and thus are mutually exclusive. In order to be able to control an external device, either by I<sup>2</sup>C or MDC/MDIO, the 2-wires *SFP Enable* bit in *Initialization Control 3* EEPROM word, that's loaded into the *CTRL\_EXT.I2C Enabled* register bit, should be set.

As the MDC/MDIO command can be targeted either to the internal PHY or to an external bus, the *MDICNFG.destination* bit is used to define the target of the transaction. Following reset, the value of the *MDICNFG.destination* bit is loaded from the *External MDIO* bit in the *Initialization Control 3* EEPROM word. When the *MDICNFG.destination* is clear, the MDIO access is always to the internal PHY and the PHY address is ignored.

Each port has its own MDC/MDIO or two wire interface bus. However, the MDC/MDIO bus of LAN port 0 may be shared by all ports configured to external PHY operation (*MDICNFG.destination* set to 1), to allow control of a multi PHY chip with a single MDC/MDIO bus.

MDIO operation using a shared bus or a separate bus is controlled by the *MDICNFG.Com\_MDIO* bit. This bit is loaded from *Initialization Control 3* EEPROM word following reset. The external port PHY Address is written in the *MDICNFG.PHYADD* register field, which is loaded from the *Initialization Control 4* EEPROM word following reset.

### 3.7.2.2.1 Detection of External I<sup>2</sup>C or MDIO Connection

When the *CTRL\_EXT.I2C Enabled* bit is set to 1, software can recognize type of external PHY control bus (MDIO or I<sup>2</sup>C) connection according to the values loaded from the EEPROM to the *MDICNFG.Destination* bit and the *CTRL\_EXT.LINK\_MODE* field in the following manner:

- External I<sup>2</sup>C operating mode - *MDICNFG.Destination* equals 0 and *CTRL\_EXT.LINK\_MODE* is not equal to 0.
- External MDIO Operating mode - *MDICNFG.Destination* equals 1 and *CTRL\_EXT.LINK\_MODE* is not equal to 0.

### 3.7.2.2.2 MDIC and MDICNFG register usage

For a MDIO read cycle, the sequence of events is as follows:

1. If default *MDICNFG* register values loaded from EEPROM need to be updated. The processor performs a PCIe write access to the *MDICNFG* register to define the:
  - *PHYADD* = Address of external PHY.
  - *Destination* = Internal or external PHY.
  - *Com\_MDIO* = Shared or separate MDIO external PHY connection.
2. The processor performs a PCIe write cycle to the *MDIC* register with:
  - *Ready* = 0b
  - *Interrupt Enable* set to 1b or 0b
  - *Opcode* = 10b (read)
  - *REGADD* = Register address of the specific register to be accessed (0 through 31).
3. The MAC applies the following sequence on the MDIO signal to the PHY:
 

<PREAMBLE><01><10><PHYADD><REGADD><Z> where Z stands for the MAC tri-stating the MDIO signal.
4. The PHY returns the following sequence on the MDIO signal <0><DATA><IDLE>.
5. The MAC discards the leading bit and places the following 16 data bits in the MII register.
6. The I350 asserts an interrupt indicating MDIO “Done” if the *Interrupt Enable* bit was set.
7. The I350 sets the *Ready* bit in the *MDIC* register indicating the Read is complete.
8. The processor might read the data from the *MDIC* register and issue a new MDIO command.

For a MDIO write cycle, the sequence of events is as follows:

1. If default *MDICNFG* register values loaded from EEPROM need to be updated. The processor performs a PCIe write cycle to the *MDICNFG* register to define the:
  - *PHYADD* = Address of external PHY.
  - *Destination* = Internal or external PHY.
  - *Com\_MDIO* = Shared or separate MDIO external PHY connection.
2. The processor performs a PCIe write cycle to the *MDIC* register with:
  - *Ready* = 0b.

- Interrupt Enable set to 1b or 0b.
  - Opcode = 01b (write).
  - REGADD = Register address of the specific register to be accessed (0 through 31).
  - Data = Specific data for desired control of the PHY.
3. The MAC applies the following sequence on the MDIO signal to the PHY:
 

<PREAMBLE><01><01><PHYADD><REGADD><10><DATA><IDLE>
  4. The I350 asserts an interrupt indicating MDIO “Done” if the *Interrupt Enable* bit was set.
  5. The I350 sets the *Ready* bit in the *MDIC* register to indicate that the write operation completed.
  6. The CPU might issue a new MDIO command.

**Note:** A MDIO read or write might take as long as 64  $\mu$ s from the processor write to the *Ready* bit assertion. When a shared MDC/MDIO bus is used, each transaction can take up to 256  $\mu$ s to complete if other ports are using the bus concurrently.

If an invalid opcode is written by software, the MAC does not execute any accesses to the PHY registers.

If the PHY does not generate a 0b as the second bit of the turn-around cycle for reads, the MAC aborts the access, sets the *E* (error) bit, writes 0xFFFF to the data field to indicate an error condition, and sets the *Ready* bit.

**Note:** After a PHY reset, access through the *MDIC* register should not be attempted for 300  $\mu$ sec.

### 3.7.2.3 Duplex Operation with Copper PHY

The I350 supports half-duplex and full-duplex 10/100 Mb/s MII mode either through the internal copper PHY or SGMII interface. However, only full-duplex mode is supported when SerDes/1000BASE-BX or 1000BASE-KX modes are used or in any 1000 Mb/s connection.

Configuration of the duplex operation of the I350 can either be forced or determined via the auto-negotiation process. Refer to [Section 3.7.4.4](#) for details on link configuration setup and resolution.

#### 3.7.2.3.1 Full Duplex

All aspects of the IEEE 802.3, 802.3u, 802.3z, and 802.3ab specifications are supported in full-duplex operation. Full-duplex operation is enabled by several mechanisms, depending on the speed configuration of the I350 and the specific capabilities of the link partner used in the application. During full-duplex operation, the I350 can transmit and receive packets simultaneously across the link interface.

In full-duplex, transmission and reception are delineated independently by the GMII/MII control signals. Transmission starts TX\_EN is asserted, which indicates there is valid data on the TX\_DATA bus driven from the MAC to the PHY/PCS. Reception is signaled by the PHY/PCS by the asserting the RX\_DV signal, which indicates valid receive data on the RX\_DATA lines to the MAC.

#### 3.7.2.3.2 Half Duplex

In half-duplex operation, the MAC attempts to avoid contention with other traffic on the link by monitoring the CRS signal provided by the PHY and deferring to passing traffic. When the CRS signal is de-asserted or after a sufficient Inter-Packet Gap (IPG) has elapsed after a transmission, frame transmission begins. The MAC signals the PHY/PCS with TX\_EN at the start of transmission.

In the case of a collision, the PHY/SGMII detects the collision and asserts the COL signal to the MAC. Frame transmission stops within four link clock times and then the I350 sends a JAM sequence onto the link. After the end of a collided transmission, the I350 backs off and attempts to re-transmit per the standard CSMA/CD method.

**Note:** The re-transmissions are done from the data stored internally in I350 MAC transmit packet buffer (no re-access to the data in host memory is performed).

The MAC behavior is different if a regular collision or a late collision is detected. If a regular collision is detected, the MAC always tries to re-transmit until the number of excessive collisions is reached. In case of late collision, the MAC retransmission is configurable. In addition, statistics are gathered on late collisions.

In the case of a successful transmission, I350 is ready to transmit any other frame(s) queued in the MAC's transmit FIFO, after the minimum inter-frame spacing (IFS) of the link has elapsed.

During transmit, the PHY is expected to signal a carrier-sense (assert the CRS signal) back to the MAC before one slot time has elapsed. The transmission completes successfully even if the PHY fails to indicate CRS within the slot time window. If this situation occurs, the PHY can either be configured incorrectly or be in a link down situation. Such an event is counted in the Transmit without CRS statistic register (refer to [Section 8.18.12](#)).

### 3.7.3 SerDes/1000BASE-BX, SGMII and 1000BASE-KX Support

The I350 can be configured to follow either SGMII, SerDes/1000BASE-BX or 1000BASE-KX standards. When in SGMII mode, the I350 can be configured to operate in 1 Gb/s, 100 Mb/s or 10 Mb/s speeds. When in the 10/100 Mb/s speed, the I350 can be configured to half-duplex mode of operation. When configured for SerDes/1000BASE-BX or 1000BASE-KX operation, the port supports only 1 Gb/s, full-duplex operation. Since the serial interfaces are defined as differential signals, internally the hardware has analog and digital blocks. Following is the initialization/configuration sequence for the analog and digital blocks.

#### 3.7.3.1 SerDes/1000BASE-BX, SGMII and 1000BASE-KX Analog Block

The analog block may require some changes to its configuration registers in order to work properly. There is no special requirement for designers to do these changes as the hardware internally updates the configuration using a default sequence or a sequence loaded from the EEPROM.

#### 3.7.3.2 SerDes/1000BASE-BX, SGMII and 1000BASE-KX PCS Block

The link setup for SerDes/1000BASE-BX, 1000BASE-KX and SGMII are described in sections [3.7.4.1](#), [3.7.4.2](#) and [3.7.4.3](#) respectively.

### 3.7.3.3 GbE Physical Coding Sub-Layer (PCS)

The I350 integrates the 802.3z PCS function on-chip. The on-chip PCS circuitry is used when the link interface is configured for SerDes/1000BASE-BX, 1000BASE-KX or SGMII operation and is bypassed for internal PHY mode.

The packet encapsulation is based on the Fiber Channel (FC0/FC1) physical layer and uses the same coding scheme to maintain transition density and DC balance. The physical layer device is the SerDes and is used for 1000BASE-SX, -L-, or -CX configurations.

#### 3.7.3.3.1 8B10B Encoding/Decoding

The GbE PCS circuitry uses the same transmission-coding scheme used in the fiber channel physical layer specification. The 8B10B-coding scheme was chosen by the standards committee in order to provide a balanced, continuous stream with sufficient transition density to allow for clock recovery at the receiving station. There is a 25% overhead for this transmission code, which accounts for the data-signaling rate of 1250 Mb/s with 1000 Mb/s of actual data.

#### 3.7.3.3.2 Code Groups and Ordered Sets

Code group and ordered set definitions are defined in clause 36 of the IEEE 802.3z standard. These represent special symbols used in the encapsulation of GbE packets. The following table contains a brief description of defined ordered sets and included for informational purposes only. Refer to clause 36 of the IEEE 802.3z specification for more details.

**Table 3-24 Brief Description of Defined Ordered Sets**

| Code | Ordered_Set     | # of Code Groups | Usage                                                                                                                                                                                                                                                                          |
|------|-----------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /C/  | Configuration   | 4                | General reference to configuration ordered sets, either /C1/ or /C2/, which is used during auto-negotiation to advertise and negotiate link operation information between link partners. Last 2 code groups contain configuration base and next page registers.                |
| /C1/ | Configuration 1 | 4                | See /C/. Differs from /C2/ in 2nd code group for maintaining proper signaling disparity <sup>1</sup> .                                                                                                                                                                         |
| /C2/ | Configuration 2 | 4                | See /C/. Differs from /C1/ in 2nd code group for maintaining proper signaling disparity <sup>1</sup> .                                                                                                                                                                         |
| /I/  | IDLE            | 2                | General reference to idle ordered sets. Idle characters are continually transmitted by the end stations and are replaced by encapsulated packet data. The transitions in the idle stream enable the SerDes to maintain clock and symbol synchronization between link partners. |
| /I1/ | IDLE 1          | 2                | See /I/. Differs from /I2/ in 2nd code group for maintaining proper signaling disparity <sup>1</sup> .                                                                                                                                                                         |
| /I2/ | IDLE 2          | 2                | See /I/. Differs from /I1/ in 2nd code group for maintaining proper signaling disparity <sup>1</sup> .                                                                                                                                                                         |
| /R/  | Carrier_Extend  | 1                | This ordered set is used to indicate carrier extension to the receiving PCS. It is also used as part of the end_of_packet encapsulation delimiter as well as IPG for packets in a burst of packets.                                                                            |

**Table 3-24 Brief Description of Defined Ordered Sets (Continued)**

| Code | Ordered_Set       | # of Code Groups | Usage                                                                                                                                                                                               |
|------|-------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /S/  | Start_of_Packet   | 1                | The SPD (start_of_packet delimiter) ordered set is used to indicate the starting boundary of a packet transmission. This symbol replaces the last byte of the preamble received from the MAC layer. |
| /T/  | End_of_Packet     | 1                | The EPD (end_of_packet delimiter) is comprised of three ordered sets. The /T/ symbol is always the first of these and indicates the ending boundary of a packet.                                    |
| /V/  | Error_Propagation | 1                | The /V/ ordered set is used by the PCS to indicate error propagation between stations. This is normally intended to be used by repeaters to indicate collisions.                                    |

1. The concept of running disparity is defined in the standard. In summary, this refers to the 1-0 and 0-1 transitions within 8B10B code groups.

### 3.7.4 Auto-Negotiation and Link Setup Features

The method for configuring the link between two link partners is highly dependent on the mode of operation as well as the functionality provided by the specific physical layer device (PHY or SerDes). In SerDes/1000BASE-BX mode, the I350 provides the complete PCS and Auto-negotiation functionality as defined in IEEE802.3 clause 36 and clause 37. In internal PHY mode, the PCS and IEEE802.3 clause 28 and clause 40 auto-negotiation functions are maintained within the PHY. In SGMII mode, the I350 supports the SGMII link auto-negotiation process, whereas the link auto-negotiation, as defined in IEEE802.3 clause 28 and clause 40, is done by the external PHY. In 1000BASE-KX mode, the I350 supports only parallel detect of 1000BASE-KX signaling and does not support the full Auto-Negotiation for Backplane Ethernet protocol as defined in IEEE802.3ap clause 73.

Configuring the link can be accomplished by several methods ranging from software forcing link settings, software-controlled negotiation, MAC-controlled auto-negotiation, to auto-negotiation initiated by a PHY. The following sections describe processes of bringing the link up including configuration of the I350 and the transceiver, as well as the various methods of determining duplex and speed configuration.

The process of determining link configuration differs slightly based on the specific link mode (internal PHY, SerDes/1000BASE-BX, SGMII or 1000BASE-KX) being used.

When operating in a SerDes/1000BASE-BX mode, the PCS layer performs auto-negotiation per clause 37 of the 802.3z standard. The transceiver used in this mode does not participate in the auto-negotiation process as all aspects of auto-negotiation are controlled by the I350.

When operating in internal PHY mode, the PHY performs auto-negotiation per 802.3ab clause 40 and extensions to clause 28. Link resolution is obtained by the MAC from the PHY after the link has been established. The MAC accomplishes this via the MDIO interface, via specific signals from the internal PHY to the MAC, or by MAC auto-detection functions.

When operating in SGMII mode, the PCS layer performs SGMII auto-negotiation per the SGMII specification. The external PHY is responsible for the Ethernet auto-negotiation process.

When operating in 1000BASE-KX mode the I350 performs parallel detect of 1000BASE-KX operation but does not implement the full Auto-Negotiation for Backplane Ethernet sequence as defined in IEEE802.3ap clause 73.

### 3.7.4.1 SerDes/1000BASE-BX Link Configuration

When using SerDes/1000BASE-BX link mode, link mode configuration can be performed using the PCS function in the I350. The hardware supports both hardware and software auto-negotiation methods for determining the link configuration, as well as allowing for a manual configuration to force the link. Hardware auto-negotiation is the preferred method.

#### 3.7.4.1.1 Signal Detect Indication

When the *CONNSW.ENRGSR*C bit is set to 1, the *SRDS\_0/1/2/3\_SIG\_DET* pins can be connected to a Signal Detect or loss-of-signal (LOS) output of the optical module that indicates when no laser light is being received when the I350 is used in a 1000BASE-SX or -LX implementation (SerDes operation). It prevents false carrier cases occurring when transmission by a non connected port couples in to the input. No standard polarity for the Signal Detect or loss-of-signal driven from different manufacturer optical modules exists. The *CTRL.ILOS* bit provides the capability to invert the signal from different external optical module vendors, and should be set when the external optical module provides a negative-true loss-of-signal.

**Note:** In internal PHY, SGMII, 1000BASE-BX and 1000BASE-KX connections energy detect source is always internal and value of *CONNSW.ENRGSR*C bit should be 0. The *CTRL.ILOS* bit also inverts the internal Link-up input that provides link status indication and thus should be set to 0 for proper operation.

#### 3.7.4.1.2 MAC Link Speed

SerDes/1000BASE-BX operation is only defined for 1000 Mb/s operation. Other link speeds are not supported. When configured for the SerDes interface, the MAC speed-determination function is disabled and the Device Status register bits (*STATUS.SPEED*) indicate a value of 10b for 1000 Mb/s.

#### 3.7.4.1.3 SerDes/1000BASE-BX Mode Auto-Negotiation

In SerDes/1000BASE-BX mode, after power up or I350 reset via *PE\_RST\_N*, the I350 initiates IEEE802.3 clause 37 auto-negotiation based on the default settings in the device control and transmit configuration or PCS Link Control Word registers, as well as settings read from the EEPROM. If enabled in the EEPROM, the I350 immediately performs auto-negotiation.

TBI mode auto-negotiation, as defined in clause 37 of the IEEE 802.3z standard, provides a protocol for two devices to advertise and negotiate a common operational mode across a GbE link. The I350 fully supports the IEEE 802.3z auto-negotiation function when using the on-chip PCS and internal SerDes.

TBI mode auto-negotiation is used to determine the following information:

- Duplex resolution (even though the I350 MAC only supports full-duplex in SerDes/1000BASE-BX mode).
- Flow control configuration.

**Notes:** Since speed for SerDes/1000BASE-BX modes is fixed at 1000 Mb/s, speed settings in the Device Control register are unaffected by the auto-negotiation process.

Auto-negotiation can be initiated at power up or by asserting *PE\_RST\_N* and enabling specific bits in the EEPROM.

The auto-negotiation process is accomplished by the exchange of /C/ ordered sets that contain the capabilities defined in the *PCS\_ANADV* register in the 3rd and 4th symbols of the ordered sets. Next page are supported using the *PCS\_NPTX\_AN* register.

Bits *FD* and *LU* in the Device Status (*STATUS*) register, and bits in the *PCS\_LSTS* register provide status information regarding the negotiated link.

Auto-negotiation can be initiated by the following:

- *PCS\_LCMD.AN\_ENABLE* transition from 0b to 1b
- Receipt of /C/ ordered set during normal operation
- Receipt of a different value of the /C/ ordered set during the negotiation process
- Transition from loss of synchronization to synchronized state (if *AN\_ENABLE* is set).
- *PCS\_LCMD.AN\_RESTART* transition from 0b to 1b

Resolution of the negotiated link determines device operation with respect to flow control capability and duplex settings. These negotiated capabilities override advertised and software-controlled device configuration.

Software must configure the *PCS\_ANADV* fields to the desired advertised base page. The bits in the Device Control register are not mapped to the *txConfigWord* field in hardware until after auto-negotiation completes. Table 3-25 lists the mapping of the *PCS\_ANADV* fields to the Config\_reg Base Page encoding per clause 37 of the standard.

**Table 3-25 802.3z Advertised Base Page Mapping**

| 15    | 14  | 13:12 | 11:9 | 8:7 | 6  | 5  | 4:0 |
|-------|-----|-------|------|-----|----|----|-----|
| Nextp | Ack | RFLT  | rsv  | ASM | Hd | Fd | rsv |

The partner advertisement can be seen in the *PCS\_LPAB* and *PCS\_LPABNP* registers.

#### 3.7.4.1.4 Forcing Link-up in SerDes/1000BASE-BX Mode

Forcing link can be accomplished by software by writing a 1b to *CTRL.SLU*, which forces the MAC PCS logic into a link-up state (enables listening to incoming characters when *SRDS[n]\_SIG\_DET* is asserted by the external optical module or an equivalent signal is asserted by the internal PHY).

**Note:** The *PCS\_LCMD.AN\_ENABLE* bit must be set to a logic zero to enable forcing link. When link is forced via the *CTRL.SLU* bit, the link does not come up unless the *SRDS[n]\_SIG\_DET* signal is asserted or an internal energy indication is received from the SerDes receiver, implying that there is a valid signal being received by the optical module or SerDes circuitry.

The source of the signal detect is defined by the *ENRGSRC* bit in the *CONNSW* register.

#### 3.7.4.1.5 HW Detection of Non-Auto-Negotiation Partner

Hardware can detect a SerDes link partner that sends idle code groups continuously, but does not initiate or answer an auto-negotiation process. In this case, hardware initiates an auto-negotiation process, and if it fails after some timeout, a link up is assumed. To enable this functionality the *PCS\_LCTL.AN\_TIMEOUT\_EN* bit should be set. This mode can be used instead of the force link mode as a way to support a partner that do not support auto-negotiation.

#### 3.7.4.2 1000BASE-KX Link Configuration

When using 1000BASE-KX link mode, link mode configuration is forced manually by software since the I350 does not support IEEE802.3 clause 73 backplane auto-negotiation.

### 3.7.4.2.1 MAC Link Speed

1000BASE-KX operation is only defined for 1000 Mb/s operation. Other link speeds are not supported. When configured for the 1000BASE-KX interface, the MAC speed-determination function is disabled and the Device Status register bits (*STATUS.SPEED*) indicate a value of 10b for 1000 Mb/s.

### 3.7.4.2.2 1000BASE-KX Auto-Negotiation

The I350 only supports parallel detection of the 1000BASE-KX link and does not support the full IEEE802.3ap clause 73 backplane auto-negotiation protocol.

### 3.7.4.2.3 Forcing Link-up in 1000BASE-KX Mode

In 1000BASE-KX mode (*EXT\_CTRL.LINK\_MODE* = 01b) the I350 should always operate in force link mode (*CTRL.SLU* bit is set to 1). The MAC PCS logic is placed in a link-up state once energy indication is received, implying that a valid signal is being received by the 1000BASE-KX circuitry. When in the link-up state PCS logic can lock on incoming characters.

**Note:** In 1000BASE-KX mode energy detect source is internal and value of *CONNSW.ENRGSR* bit should be 0. Clause 37 auto-negotiation should be disabled and the value of the *PCS\_LCMD.AN\_ENABLE* bit and *PCS\_LCMD.AN\_TIMEOUT\_EN* bit should be 0.

### 3.7.4.2.4 1000BASE-KX HW Detection of Link Partner

In 1000BASE-KX mode, hardware detects a 1000BASE-KX link partner that sends idle or none idle code groups continuously. In 1000BASE-KX operation force link-up mode is used.

## 3.7.4.3 SGMII Link Configuration

When working in SGMII mode, the actual link setting is done by the external PHY and is dependent on the settings of this PHY. The SGMII auto-negotiation process described in the sections that follow is only used to establish the MAC/PHY connection.

### 3.7.4.3.1 SGMII Auto-Negotiation

This auto-negotiation process is not dependent on the *SRDS\_[n]\_SIG\_DET* signal and the *CONNSW.ENRGSR* bit should be 0, as this signal indicates optical module signal detection and is not relevant in SGMII mode.

The outcome of this auto-negotiation process includes the following information:

- Link status
- Speed
- Duplex

This information is used by hardware to configure the MAC, when operating in SGMII mode.

Bits *FD* and *LU* of the Device Status (*STATUS*) register and bits in the *PCS\_LSTS* register provide status information regarding the negotiated link.

Auto-negotiation can be initiated by the following:

- *PCS\_LCMD.AN\_ENABLE* transition from 0b to 1b.

- Receipt of /C/ ordered set during normal operation.
- Receipt of different value of the /C/ ordered set during the negotiation process.
- Transition from loss of synchronization to a synchronized state (if *AN\_ENABLE* is set).
- *PCS\_LCMD.AN\_RESTART* transition from 0b to 1b.

Auto-negotiation determines I350 operation with respect to speed and duplex settings. These negotiated capabilities override advertised and software controlled device configuration.

When working in SGMII mode, there is no need to set the *PCAS\_ANADV* register, as the MAC advertisement word is fixed. In SGMII mode the *PCS\_LCMD.AN\_TIMEOUT\_EN* bit should be 0, since Auto-negotiation outcome is required for correct operation. The result of the SGMII level auto-negotiation can be read from the *PCS\_LPAB* register.

### 3.7.4.3.2 Forcing Link in SGMII mode

In SGMII, forcing of the link cannot be done at the PCS level, only in the external PHY. The forced speed and duplex settings are reflected by the SGMII auto-negotiation process; the MAC settings are automatically done according to this functionality.

### 3.7.4.3.3 MAC Speed Resolution

The MAC speed and duplex settings are always set according to the SGMII auto-negotiation process.

## 3.7.4.4 Copper PHY Link Configuration

When operating with the internal PHY, link configuration is generally determined by PHY auto-negotiation. The software device driver must intervene in cases where a successful link is not negotiated or the designer desires to manually configure the link. The following sections discuss the methods of link configuration for copper PHY operation.

### 3.7.4.4.1 PHY Auto-Negotiation (Speed, Duplex, Flow Control)

When using a copper PHY, the PHY performs the auto-negotiation function. The actual operational details of this operation are described in the IEEE P802.3ab draft standard and are not included here.

Auto-negotiation provides a method for two link partners to exchange information in a systematic manner in order to establish a link configuration providing the highest common level of functionality supported by both partners. Once configured, the link partners exchange configuration information to resolve link settings such as:

- Speed: - 10/100/1000 Mb/s
- Duplex: - Full or half
- Flow control operation

PHY specific information required for establishing the link is also exchanged.

**Note:** If flow control is enabled in the I350, the settings for the desired flow control behavior must be set by software in the PHY registers and auto-negotiation restarted. After auto-negotiation completes, the software device driver must read the PHY registers to determine the resolved flow control behavior of the link and reflect these in the MAC register settings (*CTRL.TFCE* and *CTRL.RFCE*).

Once PHY auto-negotiation completes, the PHY asserts a link indication (LINK) to the MAC. Software must have set the *Set Link Up* bit in the Device Control register (*CTRL.SLU*) before the MAC recognizes the LINK indication from the PHY and can consider the link to be up.

#### 3.7.4.4.2 MAC Speed Resolution

For proper link operation, both the MAC and PHY must be configured for the same speed of link operation. The speed of the link can be determined and set by several methods with the I350. These include:

- Software-forced configuration of the MAC speed setting based on PHY indications, which might be determined as follows:
  - Software reads of PHY registers directly to determine the PHY's auto-negotiated speed
  - Software reads the PHY's internal PHY-to-MAC speed indication (*SPD\_IND*) using the MAC *STATUS.SPEED* register
- Software asks the MAC to attempt to auto-detect the PHY speed from the PHY-to-MAC *RX\_CLK*, then programs the MAC speed accordingly
- MAC automatically detects and sets the link speed of the MAC based on PHY indications by using the PHY's internal PHY-to-MAC speed indication (*SPD\_IND*)

Aspects of these methods are discussed in the sections that follow.

##### 3.7.4.4.2.1 Forcing MAC Speed

There might be circumstances when the software device driver must forcibly set the link speed of the MAC. This can occur when the link is manually configured. To force the MAC speed, the software device driver must set the *CTRL.FRCSPD* (force-speed) bit to 1b and then write the speed bits in the Device Control register (*CTRL.SPEED*) to the desired speed setting. Refer to [Section 8.2.1](#) for details.

**Note:** Forcing the MAC speed using *CTRL.FRCSPD* overrides all other mechanisms for configuring the MAC speed and can yield non-functional links if the MAC and PHY are not operating at the same speed/configuration.

When forcing the I350 to a specific speed configuration, the software device driver must also ensure the PHY is configured to a speed setting consistent with MAC speed settings. This implies that software must access the PHY registers to either force the PHY speed or to read the PHY status register bits that indicate link speed of the PHY.

**Note:** Forcing speed settings by *CTRL.SPEED* can also be accomplished by setting the *CTRL\_EXT.SPD\_BYP* bit. This bit bypasses the MAC's internal clock switching logic and enables the software device driver complete control of when the speed setting takes place. The *CTRL.FRCSPD* bit uses the MAC's internal clock switching logic, which does delay the effect of the speed change.

##### 3.7.4.4.2.2 Using Internal PHY Direct Link-Speed Indication

The I350's internal PHY provides a direct internal indication of its speed to the MAC (*SPD\_IND*). When using the internal PHY, the most direct method for determining the PHY link speed and either manually or automatically configuring the MAC speed is based on these direct speed indications.

For MAC speed to be set/determined from these direct internal indications from the PHY, the MAC must be configured such that *CTRL.ASDE* and *CTRL.FRCSPD* are both 0b (both auto-speed detection and forced-speed override disabled). After configuring the Device Control register, MAC speed is re-configured automatically each time the PHY indicates a new link-up event to the MAC.

When MAC speed is neither forced nor auto-sensed by the MAC, the current MAC speed setting and the speed indicated by the PHY is reflected in the Device Status register bits *STATUS.SPEED*.

#### 3.7.4.4.3 MAC Full-/Half- Duplex Resolution

The duplex configuration of the link is also resolved by the PHY during the auto-negotiation process. The I350's internal PHY provides an internal indication to the MAC of the resolved duplex configuration using an internal full-duplex indication (FDX).

When using the internal PHY, this internal duplex indication is normally sampled by the MAC each time the PHY indicates the establishment of a good link (LINK indication). The PHY's indicated duplex configuration is applied in the MAC and reflected in the MAC Device Status register (*STATUS.FD*).

Software can override the duplex setting of the MAC via the *CTRL.FD* bit when the *CTRL.FRCDPLX* (force duplex) bit is set. If *CTRL.FRCDPLX* is 0b, the *CTRL.FD* bit is ignored and the PHY's internal duplex indication is applied.

#### 3.7.4.4.4 Using PHY Registers

The software device driver might be required under some circumstances to read from, or write to, the MII management registers in the PHY. These accesses are performed via the *MDIC* register (refer to [Section 8.2.4](#)). The MII registers enable the software device driver to have direct control over the PHY's operation, which can include:

- Resetting the PHY
- Setting preferred link configuration for advertisement during the auto-negotiation process
- Restarting the auto-negotiation process
- Reading auto-negotiation status from the PHY
- Forcing the PHY to a specific link configuration

The set of PHY management registers required for all PHY devices can be found in the IEEE P802.3ab standard. The registers for the I350 PHY are described in [Section 3.7.9](#).

#### 3.7.4.4.5 Comments Regarding Forcing Link

Forcing link in GMII/MII mode (internal PHY) requires the software device driver to configure both the MAC and PHY in a consistent manner with respect to each other as well as the link partner. After initialization, the software device driver configures the desired modes in the MAC, then accesses the PHY registers to set the PHY to the same configuration.

Before enabling the link, the speed and duplex settings of the MAC can be forced by software using the *CTRL.FRCSPEED*, *CTRL.FRCDPX*, *CTRL.SPEED*, and *CTRL.FD* bits. After the PHY and MAC have both been configured, the software device driver should write a 1b to the *CTRL.SLU* bit.

#### 3.7.4.5 Loss of Signal/Link Status Indication

For all modes of operation, an LOS/LINK signal provides an indication of physical link status to the MAC. When the MAC is configured for optical SerDes mode, the input reflects loss-of-signal connection from the optics. In backplane mode, where there is no LOS external indication, an internal indication from the SerDes receiver can be used. In SFP systems the LOS indication from the SFP can be used. In internal PHY mode, this signal from the PHY indicates whether the link is up or down; typically indicated

after successful auto-negotiation. Assuming that the MAC has been configured with *CTRL.SLU*=1b, the MAC status bit *STATUS.LU*, when read, generally reflects whether the PHY or SerDes has link (except under forced-link setup where even the PHY link indication might have been forced).

When the link indication from the PHY is de-asserted or the loss-of-signal asserted from the SerDes, the MAC considers this to be a transition to a link-down situation (such as cable unplugged, loss of link partner, etc.). If the Link Status Change (LSC) interrupt is enabled, the MAC generates an interrupt to be serviced by the software device driver.

## 3.7.5 Ethernet Flow Control (FC)

The I350 supports flow control as defined in 802.3x as well as the specific operation of asymmetrical flow control defined by 802.3z.

Flow control is implemented as a means of reducing the possibility of receive buffer overflows, which result in the dropping of received packets, and allows for local controlling of network congestion levels. This can be accomplished by sending an indication to a transmitting station of a nearly full receive buffer condition at a receiving station.

The implementation of asymmetric flow control allows for one link partner to send flow control packets while being allowed to ignore their reception. For example, not required to respond to PAUSE frames.

The following registers are defined for the implementation of flow control:

- *CTRL.RFCE* field is used to enable reception of legacy flow control packets and reaction to them.
- *CTRL.TFCE* field is used to enable transmission of legacy flow control packets.
- Flow Control Address Low, High (*FCAL/H*) - 6-byte flow control multicast address
- Flow Control Type (*FCT*) 16-bit field to indicate flow control type
- Flow Control bits in Device Control (*CTRL*) register - Enables flow control modes.
- Discard PAUSE Frames (*DPF*) and Pass MAC Control Frames (*PMCF*) in *RCTL* - controls the forwarding of control packets to the host.
- Flow Control Receive Threshold High (*FCRTH0*) - A 13-bit high watermark indicating receive buffer fullness. A single watermark is used in link FC mode.
- DMA Coalescing Receive Threshold High (*FCRTC*) - A 13-bit high watermark indicating receive buffer fullness when in DMA coalescing and TX buffer is empty. Value in this register can be higher than value placed in the *FCRTH0* register since watermark needs to be set to allow for only reception of a maximum sized RX packet before XOFF flow control takes effect and reception is stopped (refer to [Table 3-29](#) for information on flow control threshold calculation).
- Flow Control Receive Threshold Low (*FCRTL0*) - A 13-bit low watermark indicating receive buffer emptiness. A single watermark is used in link FC mode.
- Flow Control Transmit Timer Value (*FCTTV*) - a set of 16-bit timer values to include in transmitted PAUSE frame. A single timer is used in Link FC mode.
- Flow Control Refresh Threshold Value (*FCRTV*) - 16-bit PAUSE refresh threshold value

### 3.7.5.1 MAC Control Frames and Receiving Flow Control Packets

#### 3.7.5.1.1 Structure of 802.3X FC Packets

Three comparisons are used to determine the validity of a flow control frame:

1. A match on the 6-byte multicast address for MAC control frames or to the station address of the I350 (Receive Address Register 0).
2. A match on the type field.
3. A comparison of the MAC *Control Op-Code* field.

The 802.3x standard defines the MAC control frame multicast address as 01-80-C2-00-00-01.

The *Type* field in the FC packet is compared against an IEEE reserved value of 0x8808.

The final check for a valid PAUSE frame is the MAC control op-code. At this time only the PAUSE control frame op-code is defined. It has a value of 0x0001.

Frame-based flow control differentiates XOFF from XON based on the value of the *PAUSE* timer field. Non-zero values constitute XOFF frames while a value of zero constitutes an XON frame. Values in the *Timer* field are in units of pause quantum (slot time). A pause quantum lasts 64 byte times, which is converted in absolute time duration according to the line speed.

**Note:** XON frame signals the cancellation of the pause from initiated by an XOFF frame - pause for zero pause quantum.

Table 3-26 lists the structure of a 802.3X FC packet.

**Table 3-26 802.3X Packet Format**

|         |                             |
|---------|-----------------------------|
| DA      | 01_80_C2_00_00_01 (6 bytes) |
| SA      | Port MAC address (6 bytes)  |
| Type    | 0x8808 (2 bytes)            |
| Op-code | 0x0001 (2 bytes)            |
| Time    | XXXX (2 bytes)              |
| Pad     | 42 bytes                    |
| CRC     | 4 bytes                     |

### 3.7.5.1.2 Operation and Rules

The I350 operates in Link FC.

- Link FC is enabled by the *RFCE* bit in the *CTRL* Register.

**Note:** Link flow control capability is negotiated between link partners via the auto negotiation process. It is the software device driver responsibility to reconfigure the link flow control configuration after the capabilities to be used where negotiated as it might modify the value of these bits based on the resolved capability between the local device and the link partner.

Once the receiver has validated receiving an XOFF, or PAUSE frame, the I350 performs the following:

- Increments the appropriate statistics register(s)
- Sets the *Flow\_Control State* bit in the *FCSTS0* register.
- Initializes the pause timer based on the packet's *PAUSE* timer field (overwriting any current timer's value)
- Disables packet transmission or schedules the disabling of transmission after the current packet completes.

Resumption of transmission might occur under the following conditions:

- Expiration of the PAUSE timer

- Reception of an XON frame (a frame with its PAUSE timer set to 0b)

Both conditions clear the relevant *Flow\_Control State* bit in the relevant *FCSTS0* register and transmission can resume. Hardware records the number of received XON frames.

### 3.7.5.1.3 Timing Considerations

When operating at 1 Gb/s line speed, the I350 must not begin to transmit a (new) frame more than two pause-quantum-bit times after receiving a valid link XOFF frame, as measured at the wires. A pause quantum is 512-bit times.

When operating in full duplex at 100 Mb/s or 1 Gb/s line speeds, the I350 must not begin to transmit a (new) frame more than 576-bit times after receiving a valid link XOFF frame, as measured at the wire.

## 3.7.5.2 PAUSE and MAC Control Frames Forwarding

Two bits in the Receive Control register, control forwarding of PAUSE and MAC control frames to the host. These bits are *Discard PAUSE Frames (DPF)* and *Pass MAC Control Frames (PMCF)*:

- The *DPF* bit controls forwarding of PAUSE packets to the host.
- The *PMCF* bit controls forwarding of non-PAUSE packets to the host.

**Note:** When flow control reception is disabled (*CTRL.RFCE* = 0), legacy flow control packets are not recognized and are parsed as regular packets.

Table 3-27 lists the behavior of the *DPF* bit.

**Table 3-27 Forwarding of PAUSE Packet to Host (DPF Bit)**

| RFCE | DPF | Are FC Packets Forwarded to Host?                                                                   |
|------|-----|-----------------------------------------------------------------------------------------------------|
| 0    | X   | Yes. Packets needs to pass the L2 filters (refer to <a href="#">Section 7.1.1.1</a> ). <sup>1</sup> |
| 1    | 0   | Yes. Packets needs to pass the L2 filters (refer to <a href="#">Section 7.1.1.1</a> ).              |
| 1    | 1   | No if unicast, Yes, if multicast.                                                                   |

1. The flow control multicast address is not part of the L2 filtering unless explicitly required.

Table 3-28 defines the behavior of the *PMCF* bit.

**Table 3-28 Transfer of Non-PAUSE Control Packets to Host (PMCF Bit)**

| RFCE | PMCF | Are Non-FC MAC Control Packets Forwarded to Host?                                      |
|------|------|----------------------------------------------------------------------------------------|
| 0    | X    | Yes. Packets needs to pass the L2 filters (refer to <a href="#">Section 7.1.1.1</a> ). |
| X    | 1    | Yes. Packets needs to pass the L2 filters (refer to <a href="#">Section 7.1.1.1</a> ). |
| X    | 0    | No                                                                                     |

### 3.7.5.3 Transmission of PAUSE Frames

The I350 generates PAUSE packets to ensure there is enough space in its receive packet buffers to avoid packet drop. The I350 monitors the fullness of its receive packet buffers and compares it with the contents of a programmable threshold. When the threshold is reached, the I350 sends a PAUSE frame. The I350 also supports the sending of link Flow Control (FC).

**Note:** Similar to receiving link flow control packets previously mentioned, link XOFF packets can be transmitted only if this configuration has been negotiated between the link partners via the auto-negotiation process or some higher level protocol. The setting of this bit by the software device driver indicates the desired configuration.

The transmission of flow control frames should only be enabled in full-duplex mode per the IEEE 802.3 standard. Software should ensure that the transmission of flow control packets is disabled when the I350 is operating in half-duplex mode.

### 3.7.5.3.1 Operation and Rules

Transmission of link PAUSE frames is enabled by software writing a 1b to the *TFCE* bit in the Device Control register.

The I350 sends a PAUSE frame when Rx packet buffer is full above the high threshold defined in the Flow Control Receive Threshold High (*FCRTH0.RTH*) register field. When the threshold is reached, the I350 sends a PAUSE frame with its pause time field equal to *FCTTV*. The threshold should be large enough to overcome the worst case latency from the time that crossing the threshold is sensed till packets are not received from the link partner. The Flow Control Receive Threshold High value should be calculated as follows:

Flow Control Receive Threshold High = Internal RX Buffer Size - (Threshold Cross to XOFF Transmission + Round-trip Latency + XOFF Reception to Link Partner response)

Parameter values to be used for calculating the *FCRTH0.RTH* value can be found in [Table 3-29](#).

**Table 3-29 Flow Control Receive Threshold High (FCRTH0.RTH) Value Calculation**

| Latency Parameter                       | Affected by                                                             | Parameter Value                      |
|-----------------------------------------|-------------------------------------------------------------------------|--------------------------------------|
| Threshold Cross to XOFF Transmission    | Max packet size                                                         | Max packet Size * 1.25               |
| XOFF Reception to Link Partner response | Max packet size                                                         | Max packet size                      |
| Round trip latency                      | The latencies on the wire and the LAN devices at both sides of the wire | 320 Byte (for 1000Base-T operation). |

**Note:** When DMA Coalescing is enabled (*DMACR.DMAC\_EN* = 1) value placed in the *FCRTC.RTH\_Coal* field should be equal or lower than:

$$FCRTC.RTH\_Coal = FCRTH0.RTH + \text{Max packet Size} * 1.25$$

The *FCRTC.RTH\_Coal* is used as the high watermark to generate XOFF flow control packets when the internal TX buffer is empty and the I350 is executing DMA coalescing. In this case, no delay to transmission of flow control packet exists so its possible to increase level of watermark before issuing a XOFF flow control frame.

After transmitting a PAUSE frame, the I350 activates an internal shadow counter that reflects the link partner pause timeout counter. When the counter reaches the value indicated in the *FCRTV* register, then, if the PAUSE condition is still valid (meaning that the buffer fullness is still above the high watermark), a XOFF message is sent again.

Once the receive buffer fullness reaches the low water mark, the I350 sends a XON message (a PAUSE frame with a timer value of zero). Software enables this capability with the *XONE* field of the *FCRTL*.

The I350 sends an additional PAUSE frame if it has previously sent one and the packet buffer overflows. This is intended to minimize the amount of packets dropped if the first PAUSE frame did not reach its target.

### 3.7.5.3.2 Software Initiated PAUSE Frame Transmission

The I350 has the added capability to transmit an XOFF frame via software. This is accomplished by software writing a 1b to the *SWXOFF* bit of the Transmit Control register. Once this bit is set, hardware initiates the transmission of a PAUSE frame in a manner similar to that automatically generated by hardware.

The *SWXOFF* bit is self-clearing after the PAUSE frame has been transmitted.

**Note:** The Flow Control Refresh Threshold mechanism does not work in the case of software-initiated flow control. Therefore, it is the software's responsibility to re-generate PAUSE frames before expiration of the pause counter at the other partner's end.

The state of the *CTRL.TFCE* bit or the negotiated flow control configuration does not affect software generated PAUSE frame transmission.

**Note:** Software sends an XON frame by programming a 0b in the PAUSE timer field of the *FCTTV* register. Software generation of XON packet is not allowed while the hardware flow control mechanism is active, as both use the *FCTTV* registers for different purposes.

XOFF transmission is not supported in 802.3x for half-duplex links. Software should not initiate an XOFF or XON transmission if the I350 is configured for half-duplex operation.

When flow control is disabled, pause packets (XON, XOFF, and other FC) are not detected as flow control packets and can be counted in a variety of counters (such as multicast).

### 3.7.5.4 IPG Control and Pacing

The I350 supports the following modes of controlling IPG duration:

- Fixed IPG - the IPG is extended by a fixed duration

#### 3.7.5.4.1 Fixed IPG Extension

The I350 allows controlling of the IPG duration. The IPGT configuration field enables an extension of IPG in 4-byte increments. One possible use of this capability is to allow the insertion of bytes into the transmit packet after it has been transmitted by the I350 without violating the minimum IPG requirements. For example, a security device connected in series to the I350 might add security headers to transmit packets before the packets are transmitted on the network.

## 3.7.6 Loopback Support

### 3.7.6.1 General

The I350 supports the following types of internal loopback in the LAN interfaces:

- MAC Loopback (Point 1) - see [Section 3.7.6.2](#).
- PHY Loopback (Point 2) - see [Section 3.7.6.3](#).
- SerDes, SGMII or 1000BASE-KX Loopback (Point 3) - see [Section 3.7.6.4](#).

- External PHY Loopback (Point 4) - see [Section 3.7.6.5](#).

By setting the device to loopback mode, packets that are transmitted towards the line will be looped back to the host. The I350 is fully functional in these modes, just not transmitting data over the lines. [Figure 3-5](#) shows the points of loopback.

**Figure 3-5 I350 Loopback Modes**

## 3.7.6.2 MAC Loopback

In MAC loopback, the PHY and SerDes blocks are not functional and data is looped back before these blocks.

### 3.7.6.2.1 Setting the I350 to MAC Loopback Mode

The following procedure should be used to put the I350 in MAC loopback mode:

- Set *RCTL.LBM* to 2'b01 (bits 7:6)
- Set *CTRL.SLU* (bit 6, should be set by default)
- Set *CTRL.FRCSPD* and *FRCDPLEX* (bits 11 and 12)
- Set the *CTRL.FD* bit and program the *CTRL.SPEED* field to 10b (1G).
- Set *EEER.EEE\_FRC\_AN* to 1b to enable checking EEE operation in MAC loopback mode.

Filter configuration and other TX/RX processes are the same as in normal mode.

## 3.7.6.3 Internal PHY Loopback

In PHY loopback, the SerDes block is not functional and data is looped back at the end of the PHY functionality. This means all the design, that is functional in copper mode, is involved in the loopback

### 3.7.6.3.1 Setting the I350 to Internal PHY loopback Mode

The following procedure should be used to place the I350 in PHY loopback mode on any LAN port:

- Set Link mode to Internal PHY: *CTRL\_EXT.LINK\_MODE* = 00b.
- Clear *PHPM.SPD\_EN*.
- In PHY control register (*PCTRL* - Address 0 in the PHY):

- Set Duplex mode (bit 8)
- Set Loopback bit (Bit 14)
- Clear Auto Neg enable bit (Bit 12)
- Set speed using bits 6 and 13 as described in EAS.
- Register value should be:
  - For 10 Mbps 0x4100
  - For 100 Mbps 0x6100
  - For 1000 Mbps 0x4140.
- Determine the exact type of loopback using the loopback control register (*PHLBKC* - address 19d, refer to [Section 8.26.3.17](#)).

**Note:** While in MII loopback mode *PHLBKC.Force Link Status* should be set to 1 to receive valid link state and be able to Transmit and Receive normally.  
Make sure a Configure command is re-issued (loopback bits set to 00b) to cancel the loopback mode.

### 3.7.6.4 SerDes, SGMII and 1000BASE-KX Loopback

In SerDes, SGMII or 1000BASE-KX loopback, the PHY block is not functional and data is looped back at the end of the relevant functionality. This means all the design that is functional in SerDes/SGMII or 1000BASE-KX mode, is involved in the loopback.

**Note:** SerDes loopback is functional only if the SerDes link is up.

#### 3.7.6.4.1 Setting SerDes/1000BASE-BX, SGMII, 1000BASE-KX Loopback Mode

The following procedure should be used to place the I350 in SerDes loopback mode:

- Set Link mode to either SerDes, SGMII or 1000BASE-KX by:
  - 1000BASE-KX: *CTRL\_EXT.LINK\_MODE* = 01b
  - SGMII: *CTRL\_EXT.LINK\_MODE* = 10b
  - SerDes/1000BASE-BX: *CTRL\_EXT.LINK\_MODE* = 11b
- Configure SERDES to loopback: *RCTL.LBM* = 11b
- Move to Force mode by setting the following bits:
  - *CTRL.FD* (CSR 0x0 bit 0) = 1
  - *CTRL.SLU* (CSR 0x0 bit 6) = 1
  - *CTRL.RFCE* (CSR 0x0 bit 27) = 0
  - *CTRL.TFCE* (CSR 0x0 bit 28) = 0
  - *PCS\_LCTL.FORCE\_LINK* (CSR 0X4208 bit 5) = 1
  - *PCS\_LCTL.FSD* (CSR 0X4208 bit 4) = 1
  - *PCS\_LCTL.FDV* (CSR 0X4208 bit 3) = 1
  - *PCS\_LCTL.FLV* (CSR 0X4208 bit 0) = 1
  - *PCS\_LCTL.AN\_ENABLE* (CSR 0X4208 bit 16) = 0

### 3.7.6.5 External PHY Loopback

In External PHY loopback, the SerDes block is not functional and data is sent through the MDI interface and looped back using an external loopback plug. This means all the design, that is functional in copper mode, is involved in the loopback. If connected at 10/100 Mbps, the loopback will work without any special setup. For 1000 Mbps operation, the following flow should be used:

#### 3.7.6.5.1 Setting the I350 Internal PHY to External Loopback Mode

The following procedure should be used to put the I350 internal PHY into external loopback mode:

- Connect the external loopback cable to the port
- Set Link mode to PHY: `CTRL_EXT.LINK_MODE = 00b`
- In PHY Loopback Control Register - PHLBKC (Address 19d in the PHY):
  - Set External Cable mode (bit 7)
- In PHY Control Register (Address 0 in the PHY):
  - Restart auto-negotiation (Set bit 9)
- Wait for auto-negotiation to complete, then transmit and receive normally.

### 3.7.6.6 Line Loopback

In line loopback (Figure 3-6), MAC and SerDes interfaces are not functional, and the data is sent from a link partner to the PHY to test transmit and receive data paths. Frames that originate from a link partner are looped back from the PHY and sent out on the wire before reaching the MAC interface pins.

The following should be confirmed before enabling the line loopback feature:

- The PHY must first establish a full-duplex link with another PHY link partner, either through autonegotiation or through forcing the same link speed.

To enable line loopback mode once the link is established, set bit 9 to 1b in the Loopback Control Register - PHLBKC (19d; R/W) (see Section 8.26.3.17).

**Figure 3-6** Line Loopback

### 3.7.7 Energy Efficient Ethernet (EEE)

EEE (Energy Efficient Ethernet) Low Power Idle (LPI) mode defined in IEEE802.3az optionally allows power saving by switching off part of the I350 functionality when no data needs to be transmitted or/and received. Decision on whether the I350 transmit path should enter Low Power Idle mode or exit Low Power Idle mode is done according to need to transmit. Information on whether Link Partner has entered Low Power Idle mode is detected by the I350 and utilized for power saving in the receive circuitry.

When no data needs to be transmitted, a request to enter transmit Low Power Idle is issued on the internal xxMII TX interface causing the PHY to transmit sleep symbols for a predefined period of time followed by a quiet period. During LPI, the PHY periodically transmits refresh symbols that are used by the link partner to update adaptive filters and timing circuits in order to maintain link integrity. This quiet-refresh cycle continues until transmission of 'normal inter-frame' encoding on the internal xxMII interface. The PHY communicates to the link partner the move to active link state by sending Wake symbols for a predefined period of time. The PHY then enters normal operating state where data or idle symbols are transmitted.

In the receive direction, entering Low Power Idle mode is triggered by the reception of sleep symbols from the link partner. This signals that the link partner is about to enter Low Power Idle mode. After sending the sleep symbols, the link partner ceases transmission. When Link partner enters LPI the PHY indicates "assert low power idle" on the internal xxMII RX interface and the the I350 receiver disables certain functionality to reduce power consumption.

Figure 3-7 and Table 3-30 illustrate general principles of EEE LPI operation on the Ethernet Link.

**Figure 3-7 Energy Efficient Ethernet Operation**

**Table 3-30 Energy Efficient Ethernet Parameters**

| Parameter                                         | Description                                                                                              |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| Sleep Time ( $T_s$ )                              | Duration PHY sends Sleep symbols before going Quiet.                                                     |
| Quiet Duration ( $T_q$ )                          | Duration PHY remains Quiet before it must wake for Refresh period.                                       |
| Refresh Duration ( $T_r$ )                        | Duration PHY sends Refresh symbols for timing recovery and coefficient synchronization.                  |
| PHY Wake Time ( $T_{w\_PHY}$ )                    | Minimum duration PHY takes to resume to Active state after decision to Wake.                             |
| Receive System Wake Time ( $T_{w\_System\_rx}$ )  | Wait period where no data is expected to be received to give the local receiving system time to wake up. |
| Transmit System Wake Time ( $T_{w\_System\_tx}$ ) | Wait period where no data is transmitted to give the remote receiving system time to wake up.            |

### 3.7.7.1 Conditions to Enter EEE TX LPI

In the transmit direction when network interface is internal copper PHY (*CTRL\_EXT.LINK\_MODE* = 00b), entry into to EEE Low Power Idle (LPI) mode of operation is triggered when one of the following conditions exist:

1. No transmission is pending, Management does not need to transmit and internal Transmit buffer is empty and *EEER.TX\_LPI\_EN* is set to 1.
2. If the *EEER.TX\_LPI\_EN* and *EEER.LPI\_FC* bits are set to 1 and a XOFF flow control packet is received from the Link partner the I350 will move the link into TX LPI state for the Pause duration even if transmission is pending.
3. When *EEER.Force\_TLPI* is set (even if *EEER.TX\_LPI\_EN* is cleared).
  - If *EEER.Force\_TLPI* is set in mid-packet the I350 will complete packet transmission and then move TX to LPI.
  - Setting the *EEER.Force\_TLPI* bit to 1 only stops transmission of packets from the Host. The I350 will move link out of TX LPI to transmit packets from the Management even when *EEER.Force\_TLPI* is set to 1.
4. When function enters D3 state and there's no Management TX traffic, internal transmit buffers are empty and *EEER.TX\_LPI\_EN* is set to 1.

When one of the above conditions to enter TX LPI state is detected “assert low power idle” is transmitted on the internal xxMII interface and the I350 PHY transmits Sleep symbols on the network interface to communicate to the link partner entry into TX Low Power Idle link state. After Sleep symbols transmission, behavior of PHY differs according to link speed (100BASE-TX or 1000BASE-T):

1. In 100BASE-TX PHY enters low power operation in an asymmetric manner. After Sleep symbols transmission, the PHY immediately enters a low power quiet state.
2. In 1000BASE-T PHY entry into quiet state is symmetric. Only after PHY transmits sleep symbols and receives sleep symbols from the remote PHY does the PHY enter the quiet state.

After entry into quiet link state the PHY periodically transitions between quiet link state, where link is idle, to sending refresh symbols until a request to transition link back to normal (active) mode is transmitted on the internal xxMII TX interface (see [Figure 3-7](#)).

**Note:** MAC entry into TX LPI state is always asymmetric (in both 100BASE-TX and 1000BASE-T PHY operating modes).

### 3.7.7.2 Exit of TX LPI to Active Link State

The I350 will exit TX LPI link state and transition link into active link state when none of the conditions defined in [Section 3.7.7.1](#) exist. To transition into active link state the I350 transmits:

1. Normal ‘inter-frame’ encoding on the internal xxMII TX interface for a pre-defined link rate dependant period time of *Tw\_sys\_tx-min*. As a result PHY will transmit Wake symbols for a *Tw\_phy* duration followed by Idle symbols.
2. If the *Tw\_System\_tx* duration defined in the *EEER.Tw\_system* field is longer than *Tw\_sys\_tx-min* the I350 will continue transmitting the ‘inter-frame’ encoding on the internal xxMII interface until the time defined in the *EEER.Tw\_system* field has expired, before transmitting the actual data. During this period the PHY will continue transmitting Idle symbols.

**Note:** When moving out of TX LPI to transmit a 802.3x flow control frame the I350 will wait only the *Tw\_sys\_tx-min* duration before transmitting the flow control frame. It should be noted that even in this scenario, actual data will be transmitted only after the *Tw\_System\_tx* time defined in the *EEER.Tw\_system* field has expired.

### 3.7.7.3 EEE Auto-Negotiation

Auto-Negotiation provides the capability to negotiate Energy Efficient Ethernet capabilities with the Link partner using the Next page mechanism defined in IEEE802.3 Annex 28C. IEEE802.3 Auto-Negotiation is performed at power up, on command from SW, upon detection of a PHY error or following link re-connection.

During the link establishment process, both link partners indicate their EEE capabilities via the IEEE802.3 Auto-negotiation process. If EEE is supported by both link partners for the negotiated PHY type then the EEE function may be used independently in either direction.

When operating in Internal PHY mode (*CTRL\_EXT.LINK\_MODE* = 00b), the I350 supports EEE auto-negotiation. EEE capabilities advertised during Auto-negotiation can be modified via the *EEE advertisement* field in the internal PHY (refer to [Section 8.26.3.15](#)) or via the *EEER.EEE\_1G\_AN* and *EEER.EEE\_100M\_AN* bits.

### 3.7.7.4 EEE Link Level (LLDP) Capabilities Discovery

When operating in Internal PHY mode (*CTRL\_EXT.LINK\_MODE* = 00b), the I350 supports LLDP negotiation via software, using the EEE IEEE802.1AB LLDP (Link Layer Discovery Protocol) Type, Length, Value (TLV) fields defined in IEEE802.3az clause 78 and clause 79. LLDP negotiation enables negotiation of increased System wake time (Transmit  $T_w$  and Receive  $T_w$ ) to enable improving system energy efficiency.

After software negotiates a new System Wake Time Via EEE LLDP negotiation, software should update the:

1. *EEER.Tw\_system* field with the negotiated Transmit  $T_w$  time value, to increase the duration where idle symbols are transmitted following move out of EEE TX LPI state before actual data can be transmitted.
  - Value placed in *EEER.Tw\_system* field does not affect transmission of flow control packets. Depending on the technology (100BASE-TX or 1000BASE-T) flow control packet transmission is delayed following move out of EEE TX LPI state only by the minimum *Tw\_sys\_tx* time as defined in IEEE802.3az clause 78.5.

2. The *LTRMAXV* register with a value:

$$LTRMINV \leq LTRMAXV \leq LTRMINV + \text{negotiated Receive } T_w \text{ Time.}$$

3. Set *LTRC.EEEMS\_EN* bit to 1 (if bit was cleared), so that on detection of EEE RX LPI on the network an updated LTR message with the value programmed in the *LTRMAXV* register will be sent on the PCIe interface.
4. Set *EEER.TX\_LPI\_EN* bit to 1 (if bit was cleared), to enable entry into EEE LPI on TX path.

Set *EEER.RX\_LPI\_EN* bit to 1 (if bit was cleared), to enable detection of link partner entering EEE LPI state on RX path. Once the *LTRC.EEEMS\_EN* bit is set and a port detects link partner entry into the EEE LPI state on the internal xMII RX interface, the port will increase its reported latency tolerance to the value programed in the *LTRMAXV* register. If all ports have increased latency tolerance, then on detection of the RX EEE LPI state an updated LTR message will be sent on the PCIe interface.

When Wake symbols are detected on the Ethernet Link, due to link partner moving out of EEE RX LPI state, the port will report a reduced latency tolerance that equals the value placed in the *LTRMINV* register and the I350 will send on the PCIe interface a new LTR message with a reduced latency tolerance value of *LTRMINV*.

**Note:** If link is disconnected or Auto-negotiation is re-initiated, then the *LTRC.EEEMS\_EN* bit is cleared by HW. Bit should be set to 1b by software following re-execution of an IEEE LLDP negotiation.

Figure 3-8 shows the format of the IEEE TLV, meaning of the various TLV parameters can be found in IEEE802.3az clause 78 and clause 79.

**Figure 3-8 IEEE LLDP TLV**

### 3.7.7.5 Programming the I350 for IEEE Operation

To activate IEEE support when operating in Internal PHY mode (*CTRL\_EXT.LINK\_MODE* = 00b), software should program the following fields to enable IEEE on a LAN port:

1. *IPCNFG* register (refer to [Section 8.26.1](#)) if default IEEE advertised Auto-negotiation values need to be modified.
2. Set the *EEER.TX\_LPI\_EN* and *EEER.RX\_LPI\_EN* bits (refer to [Section 8.24.10](#)) to 1 to enable IEEE LPI support on TX and RX paths respectively, if result of Auto-negotiation at the specified link speed enables entry to LPI.
3. Set the *EEER.LPI\_FC* bit (refer to [Section 8.24.10](#)) if required to enable move into IEEE TX LPI state for the Pause duration when link partner sends a XOFF Flow control packet even if internal Transmit buffer is not empty and transmit descriptors are available.
4. Update *EEER.Tw\_system* field (refer to [Section 8.24.10](#)) with the new negotiated Transmit  $T_w$  time after completion of IEEE LLDP negotiation.
5. Following IEEE LLDP negotiation program the *LTRMAXV* register (refer to [Section 8.24.8](#)) with a value of:

$$LTRMINV \leq LTRMAXV \leq LTRMINV + \text{negotiated Receive } T_w \text{ Time.}$$

6. Set the *LTRC.EEEMS\_EN* bit to 1b, to enable sending an updated PCIe Latency Tolerance Report (LTR) message when detecting link partner entry into EEE RX LPI state.

**Notes:**

1. The *LTRC.EEEMS\_EN* bit is cleared following Link disconnect or Auto-negotiation and should be set to 1 by software following EEE LLDP re-negotiation.
2. The I350 waits for at least 1 second following Auto-negotiation (due to reset, Link disconnect or link speed change) and link-up indication (*STATUS.LU* set to 1, refer to [Section 8.2.2](#)) before enabling link entry into EEE TX LPI state to comply with the IEEE802.3az specification.

### 3.7.7.6 EEE Statistics

The I350 supports reporting number of EEE LPI TX and RX events via the *RLPIC* and *TLPIC* registers.

## 3.7.8 Integrated Copper PHY Functionality

The register set used to control the PHY functionality (PHYREG) is described in [Section 8.26](#). the registers can be programmed using the *MDIC* register (refer to [Section 8.2.4](#)).

### 3.7.8.1 Determining Link State

The PHY and its link partner determine the type of link established through one of three methods:

- Auto-negotiation
- Parallel detection
- Forced operation

Auto-negotiation is the only method allowed by the 802.3ab standard for establishing a 1000BASE-T link, although forced operation could be used for test purposes. For 10/100 links, any of the three methods can be used. The following sections discuss each in greater detail.

[Figure 3-9](#) provides an overview of link establishment. First the PHY checks if auto-negotiation is enabled. By default, the PHY supports auto-negotiation, see PHY Register 0, bit 12. If not, the PHY forces operation as directed. If auto-negotiation is enabled, the PHY begins transmitting Fast Link Pulses (FLPs) and receiving FLPs from its link partner. If FLPs are received by the PHY, auto-negotiation proceeds. It also can receive 100BASE-TX MLT3 and 10BASE-T Normal Link Pulses (NLPs). If either MLT3 or NLPs are received, it aborts FLP transmission and immediately brings up the corresponding half-duplex link.

**Figure 3-9 Overview of Link Establishment**

### 3.7.8.1.1 False Link

The PHY does not falsely establish link with a partner operating at a different speed. For example, the PHY does not establish a 1 Gb/s or 10 Mb/s link with a 100 MB/s link partner.

When the PHY is first powered on, reset, or encounters a link down state; it must determine the line speed and operating conditions to use for the network link.

The PHY first checks the MDIO registers (initialized via the hardware control interface or written by software) for operating instructions. Using these mechanisms, designers can command the PHY to do one of the following:

- Force twisted-pair link operation to:
  - 1000T, full duplex
  - 1000T, half duplex
  - 100TX, full duplex
  - 100TX, half duplex
  - 10BASE-T, full duplex

- 10BASE-T, half duplex
- Allow auto-negotiation/parallel-detection.

In the first six cases (forced operation), the PHY immediately begins operating the network interface as commanded. In the last case, the PHY begins the auto-negotiation/parallel-detection process.

### 3.7.8.1.2 Forced Operation

Forced operation can be used to establish 10 Mb/s and 100 Mb/s links, and 1000 Mb/s links for test purposes. In this method, auto-negotiation is disabled completely and the link state of the PHY is determined by MII Register 0.

**Note:** When speed is forced, the auto cross-over feature is not functional.

In forced operation, the designer sets the link speed (10, 100, or 1000 MB/s) and duplex state (full or half). For Gigabit (1000 MB/s) links, designers must explicitly designate one side as the master and the other as the slave.

**Note:** The paradox (per the standard): If one side of the link is forced to full-duplex operation and the other side has auto-negotiation enabled, the auto-negotiating partner parallel-detects to a half-duplex link while the forced side operates as directed in full-duplex mode. The result is spurious, unexpected collisions on the side configured to auto-negotiate.

Table 3-31 lists link establishment procedures.

**Table 3-31 Determining Duplex State Via Parallel Detection**

| Configuration                                                           | Result                                                                                                                                                |
|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Both sides set for auto-negotiate                                       | Link is established via auto-negotiation.                                                                                                             |
| Both sides set for forced operation                                     | No problem as long as duplex settings match.                                                                                                          |
| One side set for auto-negotiation and the other for forced, half-duplex | Link is established via parallel detect.                                                                                                              |
| One side set for auto-negotiation and the other for forced full-duplex  | Link is established; however, sides disagree, resulting in transmission problems (Forced side is full-duplex, auto-negotiation side is half-duplex.). |

### 3.7.8.1.3 Auto Negotiation

The PHY supports the IEEE 802.3u auto-negotiation scheme with next page capability. Next page exchange uses Register 7 to send information and Register 8 to receive them. Next page exchange can only occur if both ends of the link advertise their ability to exchange next pages.

### 3.7.8.1.4 Parallel Detection

Parallel detection can only be used to establish 10 and 100 Mb/s links. It occurs when the PHY tries to negotiate (transmit FLPs to its link partner), but instead of sensing FLPs from the link partner, it senses 100BASE-TX MLT3 code or 10BASE-T Normal Link Pulses (NLPs) instead. In this case, the PHY immediately stops auto-negotiation (terminates transmission of FLPs) and immediately brings up whatever link corresponds to what it has sensed (MLT3 or NLPs). If the PHY senses both technologies, the parallel detection fault is detected and the PHY continues sending FLPs.

With parallel detection, it is impossible to determine the true duplex state of the link partner and the IEEE standard requires the PHY to assume a half-duplex link. Parallel detection also does not allow exchange of flow-control ability (PAUSE and ASM\_DIR) or the master/slave relationship required by 1000BASE-T. This is why parallel detection cannot be used to establish GbE links.

The I350 enables the system software device driver to detect the mismatch event previously described and sets its duplex mode to the appropriate value without a need to go through another auto-negotiation sequence or breaking link. Once software detects a possible mismatch, it might instruct the I350 to change its duplex setting to either HDX or FDX mode. Software sets the *Duplex\_manual\_set* bit to indicate that duplex setting should be changed to the value indicated by the *Duplex Mode* bit in PHY Register 0. Any change in the value of the *Duplex Mode* bit in PHY Register 0 while the *Duplex\_manual\_set* bit is set to 1b would also cause a change in the device duplex setting.

The *Duplex\_manual\_set* bit is cleared on all PHY resets, following auto-negotiation, and when the link goes down. Software might track the change in duplex through the PHY *Duplex Mode* bit in Register 17 or a MAC indication.

### 3.7.8.1.7 Link Criteria

Once the link state is determined-via auto-negotiation, parallel detection or forced operation, the PHY and its link partner bring up the link.

#### 3.7.8.1.7.1 1000BASE-T

For 1000BASE-T links, the PHY and its link partner enter a training phase. They exchange idle symbols and use the information gained to set their adaptive filter coefficients. These coefficients are used to equalize the incoming signal, as well as eliminate signal impairments such as echo and cross talk.

Either side indicates completion of the training phase to its link partner by changing the encoding of the idle symbols it transmits. When both sides so indicate, the link is up. Each side continues sending idle symbols each time it has no data to transmit. The link is maintained as long as valid idle, data, or carrier extension symbols are received.

#### 3.7.8.1.7.2 100BASE-TX

For 100BASE-TX links, the PHY and its link partner immediately begin transmitting idle symbols. Each side continues sending idle symbols each time it has no data to transmit. The link is maintained as long as valid idle symbols or data is received.

In 100 Mb/s mode, the PHY establishes a link each time the scrambler becomes locked and remains locked for approximately 50 ms. Link remains up unless the descrambler receives less than 12 consecutive idle symbols in any 2 ms period. This provides for a very robust operation, essentially filtering out any small noise hits that might otherwise disrupt the link.

#### 3.7.8.1.7.3 10BASE-T

For 10BASE-T links, the PHY and its link partner begin exchanging Normal Link Pulses (NLPs). The PHY transmits an NLP every 16 ms and expects to receive one every 10 to 20 ms. The link is maintained as long as normal link pulses are received.

In 10 Mb/s mode, the PHY establishes link based on the link state machine found in 802.3, clause 14.

**Note:** 100 Mb/s idle patterns do not bring up a 10 Mb/s link.

## 3.7.8.2 Link Enhancements

The PHY offers two enhanced link functions, each of which are discussed in the sections that follow:

- SmartSpeed

- Flow control

### 3.7.8.2.1 SmartSpeed

SmartSpeed is an enhancement to auto-negotiation that enables the PHY to react intelligently to network conditions that prohibit establishment of a 1000BASE-T link, such as cable problems. Such problems might allow auto-negotiation to complete, but then inhibit completion of the training phase. Normally, if a 1000BASE-T link fails, the PHY returns to the auto-negotiation state with the same speed settings indefinitely. With SmartSpeed enabled by programming the *PHCNFG.Automatic Speed Downshift Mode* field (refer to [Section 8.26.3.20](#)), after a configurable number of failed attempts, as configured in the *PHCTRL1* register (bits 12:10 - refer to [Section 8.26.3.21](#)) the PHY automatically downgrades the highest ability it advertises to the next lower speed: from 1000 to 100 to 10 Mb/s. Once a link is established, and if it is later broken, the PHY automatically upgrades the capabilities advertised to the original setting. This enables the PHY to automatically recover once the cable plant is repaired.

#### 3.7.8.2.1.1 Using SmartSpeed

SmartSpeed is enabled by programming the *PHCNFG.Automatic Speed Downshift Mode* field (refer to [Section 8.26.3.20](#)). When SmartSpeed downgrades the PHY advertised capabilities, it sets bit *PHINT.Automatic Speed Downshift* (*PHYREG.25.1* - refer to [Section 8.26.3.23](#)). When link is established, its speed is indicated in the *PHSTAT.Speed Status* field (*PHYREG.26.9:8* - refer to [Section 8.26.3.24](#)). SmartSpeed automatically resets the highest-level auto-negotiation abilities advertised, if link is established and then lost.

The number of failed attempts allowed is configured in the *PHCTRL1* register (bits 12:10 - refer to [Section 8.26.3.21](#)).

**Note:** SmartSpeed and M/S fault - When SmartSpeed is enabled, the M/S (Master-Slave) number of Attempts Before Downshift is programmed to be less than 7, resolution is not given seven attempts to try to resolve M/S status (see IEEE 802.3 clause 40.5.2).

Time To Link with Smart Speed - in most cases, any attempt duration is approximately 2.5 seconds, in other cases it could take more than 2.5 seconds depending on configuration and other factors.

### 3.7.8.3 Flow Control

Flow control is a function that is described in Clause 31 of the IEEE 802.3 standard. It allows congested nodes to pause traffic. Flow control is essentially a MAC-to-MAC function. MACs indicate their ability to implement flow control during auto-negotiation. This ability is communicated through two bits in the auto-negotiation registers (*PHYREG.4.10* and *PHYREG.4.11*).

The PHY transparently supports MAC-to-MAC advertisement of flow control through its auto-negotiation process. Prior to auto-negotiation, the MAC indicates its flow control capabilities via *PHYREG.4.10* (Pause) and *PHYREG.4.11* (*ASM\_DIR*). After auto-negotiation, the link partner's flow control capabilities are indicated in *PHYREG.5.10* and *PHYREG.5.11*.

There are two forms of flow control that can be established via auto-negotiation: symmetric and asymmetric. Symmetric flow control is for point-to-point links; asymmetric for hub-to-end-node connections. Symmetric flow control enables either node to flow-control the other. Asymmetric flow-control enables a repeater or switch to flow-control a DTE, but not vice versa.

Table 3-32 lists the intended operation for the various settings of *ASM\_DIR* and *PAUSE*. This information is provided for reference only; it is the responsibility of the MAC to implement the correct function. The PHY merely enables the two MACs to communicate their abilities to each other.

**Table 3-32 Pause And Asymmetric Pause Settings**

| ASM_DIR settings Local (PHYREG.4.10) and Remote (PHYREG.5.10) | Pause Setting - Local (PHYREG.4.9) | Pause Setting - Remote (PHYREG.5.9) | Result                                             |
|---------------------------------------------------------------|------------------------------------|-------------------------------------|----------------------------------------------------|
| Both ASM_DIR = 1b                                             | 1                                  | 1                                   | Symmetric - Either side can flow control the other |
|                                                               | 1                                  | 0                                   | Asymmetric - Remote can flow control local only    |
|                                                               | 0                                  | 1                                   | Asymmetric - Local can flow control remote         |
|                                                               | 0                                  | 0                                   | No flow control                                    |
| Either or both ASM_DIR = 0b                                   | 1                                  | 1                                   | Symmetric - Either side can flow control the other |
|                                                               | Either or both = 0                 |                                     | No flow control                                    |

### 3.7.8.4 Management Data Interface

The PHY supports the IEEE 802.3 MII Management Interface also known as the Management Data Input/Output (MDIO) Interface. This interface enables upper-layer devices to monitor and control the state of the PHY. The MDIO interface consists of a physical connection, a specific protocol that runs across the connection, and an internal set of addressable registers.

The PHY supports the core 16-bit MDIO registers. Registers 0-10 and 15 are required and their functions are specified by the IEEE 802.3 specification. Additional registers are included for expanded functionality. Specific bits in the registers are referenced using an PHY REG X.Y notation, where X is the register number (0-31) and Y is the bit number (0-15). Refer to [Section 8.26, "PHY Software Interface" on page 683](#).

### 3.7.8.5 Internal PHY Low Power Operation and Power Management

The Internal PHY incorporates numerous features to maintain the lowest power possible.

The PHY can be entered into a low-power state according to MAC control (Power Management controls) or via PHY Register 0. In either power down mode, the PHY is not capable of receiving or transmitting packets.

#### 3.7.8.5.1 Power Down via the PHY Register

The PHY can be powered down using the control bit found in *PHYREG.0.11*. This bit powers down a significant portion of the port but clocks to the register section remain active. This enables the PHY management interface to remain active during register power down. The power down bit is active high. When the PHY exits software power-down (*PHYREG.0.11* = 0b), it re-initializes all analog functions, but retains its previous configuration settings.

#### 3.7.8.5.2 Power Management State

The internal PHY is aware of the power management state. If the PHY is not in a power down state, then PHY behavior regarding several features are different depending on the power state, refer to [Section 3.7.8.5.4](#).

### 3.7.8.5.3 Disable High Speed Power Saving Options

The I350 supports disabling 1000 Mb/s or both 1000 Mb/s and 100 Mb/s advertisement by the internal PHY regardless of the values programmed in the PHY ANA Register (address - 4d) and the PHY GCON Register (address - 9d).

This is for cases where the system doesn't support working in 1000 Mb/s or 100 Mb/s due to power limitations.

This option is enabled in the following *PHPM* register bits:

- *PHPM.Disable 1000 in non-D0a* - disable 1000 Mb/s when in non-D0a states only.
- *PHPM.Disable 100 in non-D0a* - disable 1000 Mb/s and 100 Mb/s when in non-D0a states only.
- *PHPM.Disable 1000* - disable 1000 Mb/s always.

**Note:** When Value of *PHPM.Disable 1000* bit is changed, PHY initiates Auto-negotiation without direct driver command.

### 3.7.8.5.4 Low Power Link Up - Link Speed Control

Normal Internal PHY speed negotiation drives to establish a link at the highest possible speed. The I350 supports an additional mode of operation, where the PHY drives to establish a link at a low speed. The link-up process enables a link to come up at the lowest possible speed in cases where power is more important than performance. Different behavior is defined for the D0 state and the other non-D0 states.

Table 3-33 lists link speed as function of power management state, link speed control, and GbE speed enabling:

**Table 3-33 Link Speed vs. Power State**

| Power Management State | Low Power Link Up ( <i>PHPM.1</i> , <i>PHPM.2</i> ) | GbE Disable Bits               |                                           | 100M Disable Bit                         | PHY Speed Negotiation                                                                           |
|------------------------|-----------------------------------------------------|--------------------------------|-------------------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------|
|                        |                                                     | Disable 1000 ( <i>PHPM.6</i> ) | Disable 1000 in non-D0a ( <i>PHPM.3</i> ) | Disable 100 in non-D0a ( <i>PHPM.9</i> ) |                                                                                                 |
| D0a                    | 0, Xb                                               | 0b                             | X                                         | X                                        | PHY negotiates to highest speed advertised (normal operation).                                  |
|                        |                                                     | 1b                             | X                                         | X                                        | PHY negotiates to highest speed advertised (normal operation), excluding 1000 Mb/s.             |
|                        | 1, Xb                                               | 0b                             | X                                         | X                                        | PHY goes through Low Power Link Up (LPLU) procedure, starting with advertised values.           |
|                        |                                                     | 1b                             | X                                         | X                                        | PHY goes through LPLU procedure, starting with advertised values. Does not advertise 1000 Mb/s. |
| Non-D0a                | X, 0b                                               | 0b                             | 0b                                        | 0b                                       | PHY negotiates to highest speed advertised.                                                     |
|                        |                                                     | 0b                             | 1b                                        | 0b                                       | PHY negotiates to highest speed advertised, excluding 1000 Mb/s.                                |
|                        |                                                     | 1b                             | X                                         | 0b                                       |                                                                                                 |
|                        |                                                     | X                              | X                                         | 1b                                       | PHY negotiates and advertises only 10 Mb/s                                                      |
|                        | X, 1b                                               | 0b                             | 0b                                        | 0b                                       | PHY goes through LPLU procedure, starting at 10 Mb/s.                                           |
|                        |                                                     | 0b                             | 1b                                        | 0b                                       | PHY goes through LPLU procedure, starting at 10 Mb/s. Does not advertise 1000 Mb/s.             |
|                        |                                                     | X                              | X                                         | 1b                                       | PHY negotiates and advertises only 10 Mb/s                                                      |

The Internal PHY initiates auto-negotiation without a direct driver command in the following cases:

- When the *PHPM.Disable 1000 in non-D0a* bit is set and 1000 Mb/s is disabled on D3 or Dr entry (but not in D0a), the PHY auto-negotiates on entry.
- When the *PHPM.Disable 100 in non-D0a* is set and 1000 Mb/s and 100 Mb/s are disabled on D3 or Dr entry (but not in D0a), the PHY auto-negotiates on entry.
- When *PHPM.LPLU* changes state with a change in a power management state. For example, on transition from D0a without *PHPM.LPLU* to D3 with *PHPM.LPLU*. Or, on transition from D3 with *PHPM.LPLU* to D0 without *LPLU*.
- On a transition from D0a state to a non-D0a state, or from a non-D0a state to D0a state, and *PHPM.LPLU* is set.

#### Notes:

- The Low-Power Link-Up (LPLU) feature previously described should be disabled (in both D0a state and non-D0a states) when the intended advertisement is anything other than 10 Mb/s only, 10/100 Mb/s only, or 10/100/1000 Mb/s. This is to avoid reaching (through the LPLU procedure) a link speed that is not advertised by the user.
- When the LAN PCIe Function is disabled via the *LAN\_PCI\_DIS* bit in the *Software Defined Pins Control* EEPROM word the relevant Function is in a Non-D0a state. As a result Management might operate with reduced link speed if the *LPLU, Disable 1000 in Non-D0a* or *Disable 100 in Non-D0a* EEPROM bits are set and the *MANC.Keep\_PHY\_Link\_Up* bit (also known as “Veto bit”) is cleared.
- When the *Keep\_PHY\_Link\_Up* bit (also known as “veto bit”) in the *MANC* Register is set, The PHY does not change its link speed as a result of a change in the device power state (e.g. move to D3).

#### 3.7.8.5.4.1 D0a State

A power-managed link speed control lowers link speed (and power) when highest link performance is not required. When enabled (D0 Low Power Link Up mode), any link negotiation tries to establish a low-link speed, starting with an initial advertisement defined by software.

The D0LPLU configuration bit enables *D0 Low Power Link Up*. Before enabling this feature, software must advertise to one of the following speed combinations: 10 Mb/s only, 10/100 Mb/s only, or 10/100/1000 Mb/s.

When speed negotiation starts, the PHY tries to negotiate at a speed based on the currently advertised values. If link establishment fails, the PHY tries to negotiate with different speeds; it enables all speeds up to the lowest speed supported by the partner. For example, PHY advertises 10 Mb/s only, and the partner supports 1000 Mb/s only. After the first try fails, the PHY enables 10/100/1000 Mb/s and tries again. The PHY continues to try and establish a link until it succeeds or until it is instructed otherwise. In the second step (adjusting to partner speed), the PHY also enables parallel detect, if needed. Automatic MDI/MDI-X resolution is done during the first auto-negotiation stage.

#### 3.7.8.5.4.2 Non-D0a State

The PHY might negotiate to a low speed while in non-D0a states (Dr, D0u, D3). This applies only when the link is required by one of the following: Manageability, APM Wake, or PME. Otherwise, the PHY is disabled during the non-D0 state.

The *Low Power on Link-Up* (Register *PHPM.LPLU*, is also loaded from EEPROM) bit enables reduction in link speed:

- At power-up entry to Dr state, the PHY advertises supports for 10 Mb/s only and goes through the link up process.

- At any entry to a non-D0a state (Dr, D0u, D3), the PHY advertises support for 10 Mb/s only and goes through the link up process.
- While in a non-D0 state, if auto-negotiation is required, the PHY advertises support for 10 Mb/s only and goes through the link up process.

Link negotiation begins with the PHY trying to negotiate at 10 Mb/s speed only regardless of user auto-negotiation advertisement. If link establishment fails, the PHY tries to negotiate at additional speeds; it enables all speeds up to the lowest speed supported by the partner. For example, the PHY advertises 10 Mb/s only and the partner supports 1000 Mb/s only. After the first try fails, PHY enables 10/100/1000 Mb/s and tries again. The PHY continues to try and establish a link until it succeeds or until it is instructed otherwise. In the second step (adjusting to partner speed), the PHY also enables parallel detect, if needed. Automatic MDI/MDI-X resolution is done during the first auto-negotiation stage.

### 3.7.8.5.5 Internal PHY Smart Power-Down (SPD)

Smart power-down is a link-disconnect capability applicable to all power management states. Smart Power-down combines a power saving mechanism with the fact that the link might disappear and resume.

Smart power-down is enabled by *PHPM.SPD\_EN* or by *SPD Enable* bit in the EEPROM if the following conditions are met:

1. Auto-negotiation is enabled.
2. PHY detects link loss.

While in the smart power-down state, the PHY powers down circuits and clocks that are not required for detection of link activity. The PHY is still be able to detect link pulses (including parallel detect) and wake-up to engage in link negotiation. The PHY does not send link pulses (NLP) while in SPD state; however, register accesses are still possible.

When the Internal PHY is in smart power-down mode and detects link activity, it re-negotiates link speed based on the power state and the *Low Power Link Up* bits as defined by the *PHPM.D0LPLU* and *PHPM.LPLU* bits.

**Note:** The PHY does not enter the SPD state unless auto-negotiation is enabled.

While in the SPD state, the PHY powers down all circuits not required for detection of link activity. The PHY must still be able to detect link pulses (including parallel detect) and wake up to engage in link negotiation. The PHY does not send link pulses (NLP) while in SPD state.

**Notes:** While in the link-disconnect state, the PHY must allow software access to its registers. The link-disconnect state applies to all power management states (Dr, D0u, D0a, D3). The link might change status, that is go up or go down, while in any of these states.

#### 3.7.8.5.5.1 Internal PHY Back-to-Back Smart Power-Down

While in link disconnect, the I350 monitors the link for link pulses to identify when a link is re-connected. The I350 also periodically transmits pulses (every 100 ms) to resolve the case of two I350 devices (or devices with I350-like behavior) connected to each other across the link. Otherwise, two such devices might be locked in Smart power-down mode, not capable of identifying that a link was re-connected.

Back-to-back smart power-down is enabled by the *SPD\_B2B\_EN* bit in the *PHPM* register. The default value is enabled. The *Enable* bit applies to smart power-down mode.

**Note:** This bit should not be altered by software once the I350 was set in smart power-down mode. If software requires changing the back-to-back status, it first needs to transition the PHY out of smart power-down mode and only then change the back-to-back bit to the required state.

### 3.7.8.5.6 Internal PHY Link Energy Detect

The I350 asserts the *Link Energy Detect* bit (*PHPM.Link Energy Detect*) each time energy is not detected on the link. This bit provides an indication of a cable becoming plugged or unplugged.

This bit is valid only if *PHPM.Go Link disconnect* is set to 1b.

In order to correctly deduce that there is no energy, the bit must read 0b for three consecutive reads each second.

### 3.7.8.5.7 Internal PHY Power-Down State

The I350 ports 0 to 3 enter a power-down state when none of the port's clients are enabled and therefore the internal PHY has no need to maintain a link. This can happen in one of the following cases, if the Internal PHY power-down functionality is enabled through the EEPROM *PHY Power Down Enable* bit.

1. D3/Dr state: Each Internal PHY enters a low-power state if the following conditions are met:
  - a. The LAN function associated with this PHY is in a non-D0 state
  - b. APM WOL is inactive
  - c. Manageability doesn't use this port.
  - d. ACPI PME is disabled for this port.
  - e. The *PHY Power Down Enable* EEPROM bit is set (*Initialization Control Word 2*, word 0xF, bit 6).
2. SerDes mode: Each Internal PHY is disabled when its LAN function is configured to SerDes mode.
3. LAN disable: Each Internal PHY can be disabled if its LAN function's LAN Disable input indicates that the relevant function should be disabled. Since the PHY is shared between the LAN function and manageability, it might not be desirable to power down the PHY in LAN Disable. The *PHY\_in\_LAN\_Disable* EEPROM bit determines whether the PHY (and MAC) are powered down when the LAN Disable pin is asserted. The default is not to power down.

A LAN port can also be disabled through EEPROM settings. If the *LAN\_DIS* EEPROM bit is set, the Internal PHY enters power down.

**Note:** Setting the EEPROM *LAN\_PCI\_DIS* bit does not move the internal PHY into power down. However if the *LPLU, Disable 1000 in Non-D0a* or the *Disable 100 in Non-D0a* EEPROM bits are set and the *MANC.Keep\_PHY\_Link\_Up* bit is cleared Management may operate with reduced link speed since the Function is in a Non-D0a (uninitialized) state.

## 3.7.8.6 Advanced Diagnostics

The I350 Integrated PHY incorporates hardware support for advanced diagnostics.

The hardware support enables output of internal PHY data to host memory for post processing by the software device driver.

The current diagnostics supported are:

### 3.7.8.6.1 TDR - Time Domain Reflectometry

By sending a pulse onto the twisted pair and observing the retuned signal, the following can be deduced:

1. Is there a short?
2. Is there an open?
3. Is there an impedance mismatch?
4. What is the length to any of these faults?

#### **3.7.8.6.2 Channel Frequency Response**

By doing analysis on the Tx and Rx data, it can be established that a channel's frequency response (also known as insertion loss) can determine if the channel is within specification limits. (Clause 40.7.2.1 in IEEE 802.3).

### **3.7.8.7 1000 Mb/s Operation**

#### **3.7.8.7.1 Introduction**

Figure 3-11 shows an overview of 1000BASE-T functions, followed by discussion and review of the internal functional blocks.

**Figure 3-11 1000BASE-T Functions Overview**

### 3.7.8.7.2 Transmit Functions

This section describes functions used when the Media Access Controller (MAC) transmits data through the PHY and out onto the twisted-pair connection (see [Figure 3-11](#)).

#### 3.7.8.7.2.1 Scrambler

The scrambler randomizes the transmitted data. The purpose of scrambling is twofold:

1. Scrambling eliminates repeating data patterns (also known as spectral lines) from the 4DPAM5 waveform in order to reduce EMI.
2. Each channel (A, B, C, D) has a unique signature that the receiver uses for identification.

The scrambler is driven by a 33-bit Linear Feedback Shift Register (LFSR), which is randomly loaded at power up. The LFSR function used by the master differs from that used by the slave, giving each direction its own unique signature. The LFSR, in turn, generates twelve mutually uncorrelated outputs. Eight of these are used to randomize the inputs to the 4DPAM5 and Trellis encoders. The remaining four outputs randomize the sign of the 4DPAM5 outputs.

#### **3.7.8.7.2.2 Transmit FIFO**

The transmit FIFO re-synchronizes data transmitted by the MAC to the transmit reference used by the PHY. The FIFO is large enough to support a frequency differential of up to +/- 1000 ppm over a packet size of 10 KB (jumbo frame).

#### **3.7.8.7.2.3 Transmit Phase-Locked Loop PLL**

This function generates the 125 MHz timing reference used by the PHY to transmit 4DPAM5 symbols. When the PHY is the master side of the link, the XI input is the reference for the transmit PLL. When the PHY is the slave side of the link, the recovered receive clock is the reference for the transmit PLL.

#### **3.7.8.7.2.4 Trellis Encoder**

The Trellis encoder uses the two high-order bits of data and its previous output to generate a ninth bit, which determines if the next 4DPAM5 pattern should be even or odd.

For data, this function is:

$$\text{Trellis}_n = \text{Data}_{7n-1} \text{ XOR } \text{Data}_{6n-2} \text{ XOR } \text{Trellis}_{n-3}$$

This provides forward error correction and enhances the Signal-To-Noise (SNR) ratio by a factor of 6 dB.

#### **3.7.8.7.2.5 4DPAM5 Encoder**

The 4DPAM5 encoder translates 8-byte codes transmitted by the MAC into 4DPAM5 symbols. The encoder operates at 125 MHz, which is both the frequency of the MAC interface and the baud rate used by 1000BASE-T.

Each 8-byte code represents one of 28 or 256 data patterns. Each 4DPAM5 symbol consists of one of five signal levels (-2,-1,0,1,2) on each of the four twisted pair (A,B,C,D) representing 54 or 625 possible patterns per baud period. Of these, 113 patterns are reserved for control codes, leaving 512 patterns for data. These data patterns are divided into two groups of 256 even and 256 odd data patterns. Thus, each 8-byte octet has two possible 4DPAM5 representations: one even and one odd pattern.

#### **3.7.8.7.2.6 Spectral Shaper**

This function causes the 4DPAM5 waveform to have a spectral signature that is very close to that of the MLT3 waveform used by 100BASE-TX. This enables 1000BASE-T to take advantage of infrastructure (cables, magnetics) designed for 100BASE-TX.

The shaper works by transmitting 75% of a 4DPAM5 code in the current baud period, and adding the remaining 25% into the next baud period.

### 3.7.8.7.2.7 Low-Pass Filter

To aid with EMI, this filter attenuates signal components more than 180 MHz. In 1000BASE-T, the fundamental symbol rate is 125 MHz.

### 3.7.8.7.2.8 Line Driver

The line driver drives the 4DPAM5 waveforms onto the four twisted-pair channels (A, B, C, D), adding them onto the waveforms that are simultaneously being received from the link partner.

**Figure 3-12 1000BASE-T Transmit Flow And Line Coding Scheme**

### Figure 3-13 Transmit/Receive Flow

### 3.7.8.7.3 Receive Functions

This section describes function blocks that are used when the PHY receives data from the twisted pair interface and passes it back to the MAC (see [Figure 3-13](#)).

#### **3.7.8.7.3.1 Hybrid**

The hybrid subtracts the transmitted signal from the input signal, enabling the use of simple 100BASE-TX compatible magnetics.

#### **3.7.8.7.3.2 Automatic Gain Control (AGC)**

AGC normalizes the amplitude of the received signal, adjusting for the attenuation produced by the cable.

#### **3.7.8.7.3.3 Timing Recovery**

This function re-generates a receive clock from the incoming data stream which is used to sample the data. On the slave side of the link, this clock is also used to drive the transmitter.

#### **3.7.8.7.3.4 Analog-to-Digital Converter (ADC)**

The ADC function converts the incoming data stream from an analog waveform to digitized samples for processing by the DSP core.

#### **3.7.8.7.3.5 Digital Signal Processor (DSP)**

DSP provides per-channel adaptive filtering, which eliminates various signal impairments including:

- Inter-symbol interference (equalization)
- Echo caused by impedance mismatch of the cable
- Near-end crosstalk (NEXT) between adjacent channels (A, B, C, D)
- Far-end crosstalk (FEXT)
- Propagation delay variations between channels of up to 120 ns
- Extraneous tones that have been coupled into the receive path

The adaptive filter coefficients are initially set during the training phase. They are continuously adjusted (adaptive equalization) during operation through the decision-feedback loop.

#### **3.7.8.7.3.6 Descrambler**

The descrambler identifies each channel by its characteristic signature, removing the signature and re-routing the channel internally. In this way, the receiver can correct for channel swaps and polarity reversals. The descrambler uses the same base 33-bit LFSR used by the transmitter on the other side of the link.

The descrambler automatically loads the seed value from the incoming stream of scrambled idle symbols. The descrambler requires approximately 15  $\mu$ s to lock, normally accomplished during the training phase.

#### **3.7.8.7.3.7 Viterbi Decoder/Decision Feedback Equalizer (DFE)**

The Viterbi decoder generates clean 4DPAM5 symbols from the output of the DSP. The decoder includes a Trellis encoder identical to the one used by the transmitter. The Viterbi decoder simultaneously looks at the received data over several baud periods. For each baud period, it predicts whether the symbol received should be even or odd, and compares that to the actual symbol received. The 4DPAM5 code is organized in such a way that a single level error on any channel changes an even code to an odd one

and vice versa. In this way, the Viterbi decoder can detect single-level coding errors, effectively improving the signal-to-noise (SNR) ratio by a factor of 6 dB. When an error occurs, this information is quickly fed back into the equalizer to prevent future errors.

#### **3.7.8.7.3.8 4DPAM5 Decoder**

The 4DPAM5 decoder generates 8-byte data from the output of the Viterbi decoder.

#### **3.7.8.7.3.9 100 Mb/s Operation**

The MAC passes data to the PHY over the MII. The PHY encodes and scrambles the data, then transmits it using MLT-3 for 100TX over copper. The PHY de-scrambles and decodes MLT-3 data received from the network. When the MAC is not actively transmitting data, the PHY sends out idle symbols on the line.

#### **3.7.8.7.3.10 10 Mb/s Operation**

The PHY operates as a standard 10 Mb/s transceiver. Data transmitted by the MAC as 4-bit nibbles is serialized, Manchester-encoded, and transmitted on the MDI[0] +/- outputs. Received data is decoded, de-serialized into 4-bit nibbles and passed to the MAC across the internal MII. The PHY supports all the standard 10 Mb/s functions.

#### **3.7.8.7.3.11 Link Test**

In 10 Mb/s mode, the PHY always transmits link pulses. If link test function is enabled, it monitors the connection for link pulses. Once it detects two to seven link pulses, data transmission are enabled and remain enabled as long as the link pulses or data reception continues. If the link pulses stop, the data transmission is disabled.

If the link test function is disabled, the PHY might transmit packets regardless of detected link pulses. Setting the Port Configuration register bit (PHYREG.16.14) can disable the link test function.

#### **3.7.8.7.3.12 10Base-T Link Failure Criteria and Override**

Link failure occurs if link test is enabled and link pulses stop being received. If this condition occurs, the PHY returns to the auto-negotiation phase, if auto-negotiation is enabled. Setting the Port Configuration register bit (PHYREG.16.14) disables the link integrity test function, then the PHY transmits packets, regardless of link status.

#### **3.7.8.7.3.13 Jabber**

If the MAC begins a transmission that exceeds the jabber timer, the PHY disables the transmit and loopback functions and asserts collision indication to the MAC. The PHY automatically exits jabber mode after 250-750 ms. This function can be disabled by setting bit PHYREG.16.10 = 1b.

#### **3.7.8.7.3.14 Polarity Correction**

The PHY automatically detects and corrects for the condition where the receive signal (MDI\_PLUS[0]/MDI\_MINUS[0]) is inverted. Reversed polarity is detected if eight inverted link pulses or four inverted end-of-frame markers are received consecutively. If link pulses or data are not received for 96-130 ms, the polarity state is reset to a non-inverted state.

Automatic polarity correction can be disabled by setting bit PHYREG.27.5.

### 3.7.8.7.3.15 Dribble Bits

The PHY handles dribble bits for all of its modes. If between one and four dribble bits are received, the nibble is passed across the interface. The data passed across is padded with 1's if necessary. If between five and seven dribble bits are received, the second nibble is not sent onto the internal MII bus to the MAC. This ensures that dribble bits between 1-7 do not cause the MAC to discard the frame due to a CRC error.

### 3.7.8.7.3.16 PHY Address

The External PHY MDIO Address is defined in the *MDICNFG.PHYADD* field and is loaded at power-up from EEPROM. If the *MDICNFG.Destination* bit is cleared (Internal PHY), MDIO access is always to the internal PHY.

## 3.7.9 Media Auto Sense

The I350 provides a significant amount of flexibility in pairing a LAN device with a particular type of media (such as copper or fiber-optic) as well as the specific transceiver/interface used to communicate with the media. Each MAC, representing a distinct LAN device, can be coupled with an internal copper PHY or SerDes/SGMII/1000BASE-KX interface independently. The link configuration specified for each LAN device can be specified in the *LINK\_MODE* field of the Extended Device Control (*CTRL\_EXT*) register and initialized from the EEPROM Initialization Control Word 3 associated with each LAN Port.

In some applications, software might need to be aware of the presence of a link on the media not currently active. In order to supply such an indication, any of the I350 ports can set the *AUTOSENSE\_EN* bit in the *CONNSW* register (address 0x0034) in order to enable sensing of the non active media activity.

**Note:** When in SerDes/SGMII/1000BASE-KX detect mode, software should define which indication is used to detect the energy change on the SerDes/SGMII/1000BASE-KX media. It can be either the external signal detect pin or the internal signal detect. This is done using the *CONNSW.ENRGSR* bit. The signal detect pin is normally used when connecting in SerDes mode to optical media where the receive LED provide such an indication.

Software can then enable the *OMED* interrupt in *ICR* in order to get an indication on any detection of energy in the non active media.

**Note:** The auto-sense capability can be used in either port independent of the usage of the other port.

The following sections describes the procedures that should be followed in order to enable the auto-sense mode

### 3.7.9.1 Auto sense setup

#### 3.7.9.1.1 SerDes/SGMII/1000BASE-KX Detect Mode (PHY is Active)

1. Set *CONNSW.ENRGSR* to determine the sources for the signal detect indication (1b = external *SIG\_DET*, 0b = internal SerDes electrical idle). The default of this bit is set by EEPROM.
2. Set *CONNSW.AUTOSENSE\_EN*.

- When link is detected on the SerDes/SGMII/1000BASE-KX media, the I350 sets the interrupt bit *OMED* in *ICR* and if enabled, issues an interrupt. The *CONNSW.AUTONSENSE\_EN* bit is cleared.

### 3.7.9.1.2 PHY Detect Mode (SerDes/SGMII/1000BASE-KX is active)

- Set *CONNSW.AUTONSENSE\_CONF* = 1b.
- Reset the PHY as described in [Section 4.3.4.4](#).
- Enable PHY to move to low power mode when cable is disconnected by setting the *PHPM.SPD\_EN* bit.
- Set *CONNSW.AUTONSENSE\_EN* = 1b and then clear *CONNSW.AUTONSENSE\_CONF*.
- When signal is detected on the PHY media, the I350 sets the *ICR.OMED* interrupt bit and issues an interrupt if enabled.
- The I350 puts the PHY in power down mode.

According to the result of the interrupt, software can then decide to switch to the other media.

**Note:** Assertion of *ICR.OMED* PHY is a one time event. To re-enable Auto-detect after cable is unplugged Software should clear the *CONNSW.AUTONSENSE\_EN* bit and the procedure defined above should be executed again.

### 3.7.9.2 Switching between medias.

The I350's link mode is controlled by the *CTRL\_EXT.LINK\_MODE* field. The default value for the *LINK\_MODE* setting is directly mapped from the EEPROM's *initialization Control Word 3 Link Mode* field. Software can modify the *LINK\_MODE* indication by writing the corresponding value into this register.

**Notes:** Before dynamically switching between medias, the software should ensure that the current mode of operation is not in the process of transmitting or receiving data. This is achieved by disabling the transmitter and receiver, waiting until the I350 is in an idle state, and then beginning the process for changing the link mode.

The mode switch in this method is only valid until the next hardware reset of the I350. After a hardware reset, the link mode is restored to the default setting by the EEPROM. To get a permanent change of the link mode, the default in the EEPROM should be changed.

The following procedures need to be followed to actually switch between the two modes.

#### 3.7.9.2.1 Transition to SerDes/1000BASE-KX/SGMII Modes

- Disable the receiver by clearing *RCTL.RXEN*.
- Disable the transmitter by clearing *TCTL.EN*.
- Verify the I350 has stopped processing outstanding cycles and is idle.
- Modify LINK mode to SerDes, 1000BASE-KX or SGMII by setting *CTRL\_EXT.LINK\_MODE* to 11b, 01b or 10b respectively.
- Set up the link as described in [Section 4.6.7.3](#), [Section 4.6.7.4](#) or [Section 4.6.7.5](#).
- Set up Tx and Rx queues and enable Tx and Rx processes.

#### 3.7.9.2.2 Transition to Internal PHY Mode

- Disable the receiver by clearing *RCTL.RXEN*.
- Disable the transmitter by clearing *TCTL.EN*.

3. Verify the I350 has stopped processing outstanding cycles and is idle.
4. Modify LINK mode to PHY mode by setting `CTRL_EXT.LINK_MODE` to 00b.
5. Set link-up indication by setting `CTRL.SLU`.
6. Reset the PHY as described in [Section 4.3.4.4](#).
7. Set up the link as described in [Section 4.6.7.2](#).
8. Set up the Tx and Rx queues and enable the Tx and Rx processes.

§ §

## 4 Initialization

### 4.1 Power Up

#### 4.1.1 Power-Up Sequence

Figure 4-1 shows the power-up sequence from power ramp up and to when the I350 is ready to accept host commands.

**Figure 4-1 Power-Up - General Flow**

**Note:** The Keep\_PHY\_Link\_Up bit (Veto bit) is set by firmware when the BMC is running IDER or SoL. Its purpose is to prevent interruption of these processes when power is being turned on.

## 4.1.2 Power-Up Timing Diagram

**Figure 4-2 Power-Up Timing Diagram**

**Table 4-1 Notes to Power-Up Timing Diagram**

| Note |                                                                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Xosc is stable $t_{xog}$ after the Power is stable                                                                                                                    |
| 2    | Internal Reset is released after all power supplies are good and $t_{ppg}$ after Xosc is stable.                                                                      |
| 3    | An EEPROM read starts on the rising edge of the internal Reset or LAN_PWR_GOOD.                                                                                       |
| 4    | After reading the EEPROM, PHY might exit power down mode.                                                                                                             |
| 5    | APM Wakeup and/or manageability might be enabled based on EEPROM contents.                                                                                            |
| 6    | The PCIe reference clock is valid $t_{PE\_RST-CLK}$ before the de-assertion of PE_RST# (according to PCIe spec).                                                      |
| 7    | PE_RST# is de-asserted $t_{PVRGL}$ after power is stable (according to PCIe spec).                                                                                    |
| 8    | De-assertion of PE_RST# causes the EEPROM to be re-read, asserts PHY power-down (except if veto bit also known as Keep_PHY_Link_Up bit is set), and disables Wake Up. |
| 9    | After reading the EEPROM, PHY exits power-down mode.                                                                                                                  |
| 10   | Link training starts after $t_{pgtrn}$ from PE_RST# de-assertion.                                                                                                     |
| 11   | A first PCIe configuration access might arrive after $t_{pgcfg}$ from PE_RST# de-assertion.                                                                           |
| 12   | A first PCI configuration response can be sent after $t_{pgres}$ from PE_RST# de-assertion                                                                            |
| 13   | Writing a 1 to the Memory Access Enable bit in the PCI Command Register transitions the device from D0u to D0 state.                                                  |

## 4.2 Reset Operation

The I350 has a number of reset sources described below. Following the reset Software driver should verify that the *EEMNGCTL.CFG\_DONE* bit (refer to [Section 8.4.6.1](#)) is set to 1b and no errors were reported in the *FWSM.Ext\_Err\_Ind* (refer to [Section 8.7.2](#)) field.

### 4.2.1 Reset Sources

The I350 reset sources are described below:

#### 4.2.1.1 LAN\_PWR\_GOOD

The I350 has an internal mechanism for sensing the power pins. Once the power is up and stable, the I350 creates an internal reset. This reset acts as a master reset of the entire chip. It is level sensitive, and while it is zero holds all of the registers in reset. LAN\_PWR\_GOOD is interpreted to be an indication that device power supplies are all stable. LAN\_PWR\_GOOD changes state during system power-up.

#### 4.2.1.2 PE\_RST\_N

The de-assertion of PE\_RST\_N indicates that both the power and the PCIe clock sources are stable. This pin asserts an internal reset also after a D3cold exit. Most units are reset on the rising edge of PE\_RST\_N. The only exception is the PCIe unit, which is kept in reset while PE\_RST\_N is asserted (level).

#### 4.2.1.3 In-Band PCIe Reset

The I350 generates an internal reset in response to a Physical layer message from the PCIe or when the PCIe link goes down (entry to Polling or Detect state). This reset is equivalent to PCI reset in previous (PCI) gigabit LAN controllers.

#### 4.2.1.4 D3hot to D0 Transition

This is also known as ACPI Reset. the I350 generates an internal reset on the transition from D3hot power state to D0 (caused after configuration writes from D3 to D0 power state). Note that this reset is per function and resets only the function that transitions from D3hot to D0 (refer to [Section 5.2.3](#) for additional information).

When the *PMCSR.No\_Soft\_Reset* bit in the configuration space is set on transition from D3hot to D0 the I350 will reset internal CSRs (similar to *CTRL.RST* assertion) but will not reset registers in the PCIe configuration space. If the *PMCSR.No\_Soft\_Reset* bit is cleared the I350 will reset all per function registers except for registers defined as sticky in the configuration space.

**Note:** Regardless of the value of the *PMCSR.No\_Soft\_Reset* bit the function will be reset (including bits that are not defined as sticky in PCIe configuration space) if the Link state transitions to the L2/L3 Ready state, on transition from D3cold to D0, if FLR is asserted or if transition D3hot to D0 is caused by assertion of PCIe reset (PE\_RST pin).

**Note:** Software drivers should implement the handshake mechanism defined in [Section 5.2.3.3](#) to verify that all pending PCIe completions are done, before moving the I350 to D3.

#### 4.2.1.5 Function Level Reset (FLR)

The FLR bit is required for the PF and per VF (Virtual Function). Setting of this bit for a VF resets only the part of the logic dedicated to the specific VF and does not influence the shared part of the port. Setting the PF FLR bit resets the entire function.

##### 4.2.1.5.1 PF (Physical Function) FLR or FLR in non-IOV Mode

A FLR reset to a function is issued, by setting bit 15 in the *Device Control* configuration register (refer to [Section 9.5.6.5](#)), is equivalent to a D0 ⇒ D3 ⇒ D0 transition. The only difference is that this reset does not require driver intervention in order to stop the master transactions of this function. This reset is per function and resets only the function without affecting activity of other functions or LAN ports. In an IOV enabled system, this reset resets all the VFs attached to the PF.

The EEPROM is partially reloaded after an FLR reset. The words read from EEPROM at FLR are the same as read following a full software reset. A list of these words can be found in [Section 3.3.1.3](#).

A FLR reset to a function resets all the queues, interrupts, and statistics registers attached to the function. It also resets PCIe R/W configuration bits as well as disables transmit and receive flows for the queues allocated to the function. All pending read requests are dropped and PCIe read completions to the function might be completed as unexpected completions and silently discarded (following update of flow control credits) without logging or signaling as an error.

**Note:** If software initiates a FLR when the *Transactions Pending* bit in the *Device Status* configuration register is set to 1b (refer to [Section 9.5.6.6](#)), then software must not initialize the function until allowing time for any associated completions to arrive. The *Transactions Pending* bit is cleared upon completion of the FLR.

##### 4.2.1.5.2 VF (Virtual Function) FLR (Function Level Reset)

An FLR reset to a VF function resets all the queues, interrupts, and statistics registers attached to this VF. It also resets the PCIe R/W configuration bits allocated to this function. It also disables Tx and Rx flow for the queues allocated to this VF. All pending read requests are dropped and PCIe read completions to this function might be completed as unsupported requests.

##### 4.2.1.5.3 IOV (IO Virtualization) Disable

Clearing of the IOV enable bit in the IOV structure is equivalent to a VFLR to all the active VFs in the PF.

## 4.3 Software Reset

### 4.3.1 Full Port Software Reset (RST)

Software can reset a port in the I350 by setting the Port Software Reset (*CTRL.RST*) in the Device Control Register. The port software reset (*CTRL.RST*) is per function and resets only the function that received the software reset. Following the reset the PCI configuration space (configuration and mapping) of the device is unaffected. Prior to issuing software reset the driver needs to operate the master disable algorithm as defined in [Section 5.2.3.3](#).

The *CTRL.RST* bit is provided primarily to recover from an indeterminate or suspected Port hung hardware state. Most registers (receive, transmit, interrupt, statistics, etc.) and state machines in the port are set to their power-on reset values, approximating the state following a power-on or PCIe reset (refer to [Table 4-3](#) for further information on affects of Software reset). However, PCIe configuration registers and logic common to all ports is not reset, leaving the device mapped into system memory space and accessible by a driver.

**Note:** To ensure that software reset has fully completed and that the I350 responds correctly to subsequent accesses after setting the *CTRL.RST* bit, the driver should wait at least 3 milliseconds before accessing any register and then verify that *EEC.Auto\_RD* is set to 1b and that the *STATUS.PF\_RST\_DONE* bit is set to 1b.

When asserting the *CTRL.RST* software reset bit, only some EEPROM bits related to the specific function are re-read (refer to [Section 3.3.1.3](#)). Bits re-read from EEPROM are reset to default values.

### 4.3.2 Physical Function (PF) Software Reset

A software reset by the PF in IOV mode has the same consequences as a port software reset in a non-IOV mode (refer to [Table 4-3](#) for further information on affects of PF Software reset). The procedure for PF software reset is as follows:

- The PF driver disables master accesses by the device through the Master Disable mechanism (refer to [Section 5.2.3.3](#)). Master Disable affects all VFs traffic.
- Execute the procedure described in [Section 4.6.11.2.3](#) to synchronize between the PF and VFs.

VFs are expected to timeout and check on the *VFMailbox.RSTD* bit in order to identify a PF software reset event. The *VFMailbox.RSTD* bits are cleared on read.

### 4.3.3 VF Software Reset

A software reset applied to a VF is equivalent to a FLR reset to this VF with the exception that the PCIe configuration bits allocated to this function are not reset. This can be activated by setting the *VFCTRL.RST* bit (refer to [Table 4-4](#) for further information on affects of Software reset).

### 4.3.4 Device Software Reset (DEV\_RST)

Software can reset all I350 ports by setting the Device Reset bit (*CTRL.DEV\_RST*) in the Device Control Register. The Device Reset (*CTRL.DEV\_RST*) resets all functions and common logic (refer to [Table 4-2](#) for further information on affects of Device Software reset). PCI configuration space (configuration and mapping) of the device is unaffected.

Device Reset (*CTRL.DEV\_RST*) can be used to globally reset the entire component, if the *DEV\_RST\_EN* bit in *Initialization Control 4* EEPROM word is set. This bit is provided as a last-ditch software mechanism to recover from an indeterminate or suspected hardware hung state that could not be resolved by setting the *CTRL.RST* bit. When setting *CTRL.DEV\_RST*, most registers (receive, transmit, interrupt, statistics, etc.) and state machines on ports are set to their default values similar to the state following a Function Level reset on all functions. PCIe configuration registers are not reset, leaving the device mapped into system memory space and accessible by the drivers.

When *CTRL.DEV\_RST* is asserted by software on a LAN port, all LAN ports (including LAN ports that didn't initiate the reset) are placed in a reset state. To notify software device drivers on all ports that *CTRL.DEV\_RST* has been asserted, an interrupt is generated and the *ICR.DRSTA* bit is set on all ports that didn't initiate the Device reset. In addition the *STATUS.DEV\_RST\_SET* bit is set on all ports to indicate that Device reset was asserted.

Prior to issuing Device reset the driver needs to:

1. Get ownership of the Device reset functionality by sending message via the mailbox mechanism described in [Section 4.7.3](#) and receiving acknowledge message from other drivers.
2. Initiate the master disable algorithm as defined in [Section 5.2.3.3](#).

**Note:** To ensure that Device reset has fully completed and that the I350 responds correctly to subsequent accesses, wait at least 3 milliseconds after setting *CTRL.DEV\_RST* before attempting to access any other register.

Following Device Reset assertion or reception of Device Reset interrupt (*ICR.DRSTA*) software should initiate the following steps to re-initialize the port:

1. Wait for the *GCR.DEV\_RST In progress* bit to be cleared.
2. Read *STATUS.DEV\_RST\_SET* bit and clear bit by write 1.
3. Verify that *EEC.Auto\_RD* is set to 1b and EEPROM Auto load completed, since setting the Device reset bit (*CTRL.DEV\_RST*) causes EEPROM bits related to all ports to be re-read (refer to [Section 3.3.1.3](#)).
4. Check that the *STATUS.PF\_RST\_DONE* bit is set to 1b to verify that internal reset has completed.
5. Re-initialize the port.
6. Check *STATUS.DEV\_RST\_SET* bit and verify that bit is still 0. If bit is set, return to [1.](#) and re-start initialization process.
7. Driver that initiated the Device reset should release ownership of Device Reset and Mailbox using the flow described in [Section 4.7.3](#).

#### 4.3.4.1 BME (Bus Master Enable)

Disabling Bus Master activity of a function by clearing the Configuration *Command register.BME* bit to 0, resets all DMA activities and MSI/MSIx operations related to the port. The Master disable is per function and resets only the DMA activities related to this function without affecting activity of other functions or LAN ports. Configuration accesses and target accesses to the function are still enabled and BMC can still transmit and receive packets on the port.

A Master Disable to a function resets all the queues and DMA related interrupts attached to this function. It also disables the transmit and receive flows for the queues allocated to this function. All pending read requests are dropped and PCIe read completions to this function might be completed as unexpected completions and silently discarded (following update of flow control credits) without logging or signaling it as an error.

**Note:** Prior to issuing a master disable the Driver needs to implement the master disable algorithm as defined in [Section 5.2.3.3](#). After Master Enable is set back to 1 driver should re-initialize the transmit and receive queues.

#### 4.3.4.2 Force TCO

This reset is generated when manageability logic is enabled and BMC detects that the I350 does not receive or transmit data correctly. Force TCO reset is enabled if the *Reset on Force TCO* bit in the *Management Control* EEPROM word is set 1. [Table 4-3](#) describes affects of TCO reset on the I350 functionality.

Force TCO reset is generated in pass through mode when BMC issues a Force TCO command with bit 1 set and the above conditions exist.

#### 4.3.4.3 EEPROM Reset

Writing a 1 to the EEPROM Reset bit of the Extended Device Control Register (*CTRL\_EXT.EE\_RST*) causes the I350 to re-read the per-function configuration from the EEPROM, setting the appropriate bits in the registers loaded by the EEPROM.

#### 4.3.4.4 PHY Reset

Software can write a 1 to the PHY Reset bit of the Device Control Register (*CTRL.PHY\_RST*) to reset the internal PHY. The PHY is internally configured after a PHY reset.

**Note:** The internal PHY should not be reset using PHYREG 0 bit 15 (*PCTRL.Reset*), since in this case the internal PHY configuration process is bypassed and there is no guarantee the PHY will operate correctly.

As the PHY may be accessed by the internal firmware and the driver software, the driver software should coordinate any PHY reset with the firmware using the following procedure:

1. Check that *MANC.BLK\_Phy\_Rst\_On\_IDE* (offset 0x5820 bit 18) is cleared. If it is set, the BMC requires a stable link and thus the PHY should not be reset at this stage. The driver may skip the PHY reset if not mandatory or wait for *MANC.BLK\_Phy\_Rst\_On\_IDE* to clear. Refer to [Section 4.3.6](#) for more details.
2. Take ownership of the relevant PHY (on port 0,1,2 or 3) using the following flow:
  - a. Get ownership of the software/software semaphore *SWSM.SMBI* bit (offset 0x5B50 bit 0).
    - Read the *SWSM* register.
    - If *SWSM.SMBI* is read as zero, the semaphore was taken.
    - Otherwise, go back to step a.
    - This step assure that other software will not access the shared resources register (*SW\_FW\_SYNC*).
  - b. Get ownership of the software/firmware semaphore *SWSM.SWESMBI* bit (offset 0x5B50 bit 1):
    - Set the *SWSM.SWESMBI* bit.

- Read *SWSM*.
  - If *SWSM.SWESMBI* was successfully set - the semaphore was acquired - otherwise, go back to step a.
  - This step assure that the internal firmware will not access the shared resources register (*SW\_FW\_SYNC*).
- c. Software reads the Software-Firmware Synchronization Register (*SW\_FW\_SYNC*) and checks both bits in the pair of bits that control the PHY it wishes to own.
- If both bits are cleared (both firmware and other software does not own the PHY), software sets the software bit in the pair of bits that control the resource it wishes to own.
  - If one of the bits is set (firmware or other software owns the PHY), software tries again later.
- d. Release ownership of the software/firmware semaphore by clearing the *SWSM.SWESMBI* bit.
3. Drive PHY reset bit in CTRL bit 31.
4. Wait 100  $\mu$ s.
5. Release PHY reset in CTRL bit 31.
6. Release ownership of the relevant PHY to the FW using the following flow:
- a. Get ownership of the software/firmware semaphore *SWSM.SWESMBI* (offset 0x5B50 bit 1):
- Set the *SWSM.SWESMBI* bit.
  - Read *SWSM*.
  - If *SWSM.SWESMBI* was successfully set - the semaphore was acquired - otherwise, go back to step a.
  - Clear the bit in *SW\_FW\_SYNC* that control the software ownership of the resource to indicate this resource is free.
  - Release ownership of the software/firmware semaphore by clearing the *SWSM.SWESMBI* bit.
7. Wait for the relevant *CFG\_DONE* bit (*EEMNGCTL.CFG\_DONE0*, *EEMNGCTL.CFG\_DONE1*, *EEMNGCTL.CFG\_DONE2* or *EEMNGCTL.CFG\_DONE3*).
8. Take ownership of the relevant PHY using the following flow:
- a. Get ownership of the software/firmware semaphore *SWSM.SWESMBI* (offset 0x5B50 bit 1):
- Set the *SWSM.SWESMBI* bit.
  - Read *SWSM*.
  - If *SWSM.SWESMBI* was successfully set - the semaphore was acquired - otherwise, go back to step a.
  - This step assure that the internal firmware will not access the shared resources register (*SW\_FW\_SYNC*).
- b. Software reads the Software-Firmware Synchronization Register (*SW\_FW\_SYNC*) and checks both bits in the pair of bits that control the PHY it wishes to own.
- If both bits are cleared (both firmware and other software does not own the PHY), software sets the software bit in the pair of bits that control the resource it wishes to own.
  - If one of the bits is set (firmware or other software owns the PHY), software tries again later.
- c. Release ownership of the software/software semaphore and the software/firmware semaphore by clearing *SWSM.SMBI* and *SWSM.SWESMBI* bits.
9. Configure the PHY.
10. Release ownership of the relevant PHY using the flow described in [Section 4.7.2](#).

**Note:** Software PHY ownership should not exceed 100 mS. If Software takes PHY ownership for a longer duration, Firmware may implement a timeout mechanism and take ownership of the PHY.

## 4.3.5 Registers and Logic Reset Affects

The resets affect the following registers and logic:

**Table 4-2 I350 Reset Affects - Common Resets**

| Reset Activation                                        | LAN_PWR_GOOD | PE_RST_N | SW_DEV_RST | In-Band PCIe Reset | FW Reset | Notes  |
|---------------------------------------------------------|--------------|----------|------------|--------------------|----------|--------|

| Strapping Pins                                          |            |     |                          |           |          |           |        |

**Table 4-4 I350 Reset Affects -Virtual Function Resets**

| Reset Activation                     | VFLR <sup>20</sup> . | Software Reset | Notes |
|--------------------------------------|----------------------|----------------|-------|
| Interrupt registers                  | X                    | X              | 14.   |
| Queue disable                        | X                    | X              |       |
| VF specific PCIe configuration space | X                    |                | 13.   |
| Data path                            |                      |                |       |

**Notes:**

1. If AUX\_POWER = 0b the Wakeup Context is reset (*PME\_Status* and *PME\_En* bits should be 0b at reset if the I350 does not support PME from D3cold).
2. The MMS unit must configure the PHY after any PHY reset.
3. The following register fields do not follow the general rules above:
  - a. "CTRL.SDP0\_IODIR, CTRL.SDP1\_IODIR, CTRL\_EXT.SDP2\_IODIR, CTRL\_EXT.SDP3\_IODIR, CONNSW.ENRGSRC field, CTRL\_EXT.SFP\_Enable, CTRL\_EXT.LINK\_MODE, CTRL\_EXT.EXT\_VLAN and LED configuration registers are reset on LAN\_PWR\_GOOD only. Any EEPROM read resets these fields to the values in the EEPROM.
  - b. The Aux Power Detected bit in the PCIe Device Status register is reset on LAN\_PWR\_GOOD and PE\_RST\_N (PCIe reset) assertion only.
  - c. FLA - reset on LAN\_PWR\_GOOD Internal Power only.
  - d. The bits mentioned in the next note.
4. The following registers are part of this group:
  - a. VPD registers
  - b. Max payload size field in PCIe Capability Control register (offset 0xA8).
  - c. Active State Link PM Control field, Common Clock Configuration field and Extended Synch field in PCIe Capability Link Control register (Offset 0xB0).
  - d. *ARI enable* bit in *IOV capability Command* register (offset 0x168).
  - e. Read Completion Boundary in the PCIe Link Control register (Offset 0xB0).
5. The following registers are part of this group:
  - a. SWSM
  - b. GCR (only part of the bits - see register description for details)
  - c. FUNCTAG
  - d. GSCL\_1/2/3/4
  - e. GSCN\_0/1/2/3
  - f. SW\_FW\_SYNC - only part of the bits - see register description for details.
6. The following registers are part of this group:
  - a. *MSIX control* register, *MSIX PBA* and *MSIX per vector mask*.
7. The Wake Up Context is defined in the PCI Bus Power Management Interface Specification (Sticky bits). It includes:
  - *PME\_En* bit of the Power Management Control/Status Register (*PMCSR*).
  - *PME\_Status* bit of the Power Management Control/Status Register (*PMCSR*).
  - *Aux\_En* in the PCIe registers

- The device Requester ID (since it is required for the PM\_PME TLP).  
The shadow copies of these bits in the Wakeup Control Register are treated identically.
- 8. Refers to bits in the Wake Up Control Register that are not part of the Wake-Up Context (the *PME\_En* and *PME\_Status* bits).
- 9. The Wake Up Status Registers include the following:
  - a. Wake Up Status Register
  - b. Wake Up Packet Length.
  - c. Wake Up Packet Memory.
- 10. The manageability control registers refer to the following registers:
  - a. *MANC* 0x5820
  - b. *MFUTP0-3* 0x5030 - 0x503C
  - c. *MNGONLY* 0x5864
  - d. *MAVTV0-7* 0x5010 - 0x502C
  - e. *MDEF0-7* 0x5890 - 0x58AC
  - f. *MDEF\_EXT* 0x5930 - 0x594C
  - g. *METF0-3* 0x5060 - 0x506C
  - h. *MIPAF0-15* 0x58B0 - 0x58EC
  - i. *MMAH/MMAL0-1* 0x5910 - 0x591C
  - j. FWSM
- 11. The Wake-up Management Registers include the following:
  - a. Wake Up Filter Control
  - b. IP Address Valid
  - c. IPv4 Address Table
  - d. IPv6 Address Table
  - e. Flexible Filter Length Table
  - f. Flexible Filter Mask Table
- 12. The Other Configuration Registers include:
  - a. General Registers
  - b. Interrupt Registers
  - c. Receive Registers
  - d. Transmit Registers
  - e. Statistics Registers
  - f. Diagnostic Registers

Of these registers, *MTA[n]*, *VFTA[n]*, *WUPM[n]*, *FTFT[n]*, *FHFT[n]*, *FHFT\_EXT[n]*, *TDBAH/TDBAL*, and *RDBAH/RDVAL* registers have no default value. If the functions associated with the registers are enabled they must be programmed by software. Once programmed, their value is preserved through all resets as long as power is applied to the I350.

**Note:** In situations where the device is reset using the software reset *CTRL.RST* or *CTRL.DEV\_RST* the transmit data lines are forced to all zeros. This causes a substantial number of symbol errors to be detected by the link partner. In TBI mode, if the duration is long enough, the link partner might restart the Auto-Negotiation process by sending “break-link” (/C/ codes with the configuration register value set to all zeros).

13. These registers include:
  - a. MSI/MSI-X enable bits
  - b. BME
  - c. Error indications
14. These registers include:
  - a. VTEICS
  - b. VTEIMS
  - c. VTEIAC
  - d. VTEIAM
  - e. VTEITR 0-2
  - f. VTIVAR0
  - g. VTIVAR\_MISC
  - h. PBACL
  - i. VFMailbox
15. These registers include:
  - a. RXDCTL.Enable
  - b. Adequate bit in *VFTE* and *VFRE* registers.
16. The contents of the following memories are cleared to support the requirements of PCIe FLR:
  - a. The Tx packet buffers
  - b. The Rx packet buffers
17. Includes *EEC.REQ*, *EEC.GNT*, *FLA.REQ* and *FLA.GNT* fields.
18. The following DMA Registers are cleared only by LAN\_PWR\_GOOD, PCIe Reset or *CTRL.DEV\_RST*: *DMCTLX*, *DTPARS*, *DRPARS* and *DDPARS*.
19. *CTRL.DEV\_RST* assertion causes read of function related sections for all ports
20. A VFLR does not reset the configuration of the VF, only disables the interrupts and the queues.

### 4.3.6 PHY Behavior During a Manageability Session

During some manageability sessions (e.g. an IDER or SoL session as initiated by an external BMC), the platform is reset so that it boots from a remote media. This reset must not cause the Ethernet link to drop since the manageability session is lost. Also, the Ethernet link should be kept on continuously during the session for the same reasons. The I350 therefore limits the cases in which the internal PHY would restart the link, by masking two types of events from the internal PHY:

- PE\_RST# and PCIe resets (in-band and link drop) do not reset the PHY during such a manageability session
- The PHY does not change link speed as a result of a change in power management state, to avoid link loss. For example, the transition to D3hot state is not propagated to the PHY.
  - Note however that if main power is removed, the PHY is allowed to react to the change in power state (i.e., the PHY might respond in link speed change). The motivation for this exception is to reduce power when operating on auxiliary power by reducing link speed.

The capability described in this section is disabled by default on LAN Power Good reset. The *Keep\_PHY\_Link\_Up\_En* bit in the EEPROM must be set to '1' to enable it. Once enabled, the feature is enabled until the next LAN Power Good (i.e., I350 does not revert to the hardware default value on PE\_RST#, PCIe reset or any other reset but LAN Power Good).

When the *Keep\_PHY\_Link\_Up* bit (also known as “veto bit”) in the MANC Register is set, the following behaviors are disabled:

- The PHY is not reset on PE\_RST# and PCIe resets (in-band and link drop). Other reset events are not affected - LAN Power Good reset, Device Disable, Force TCO, and PHY reset by software.
- The PHY does not change its power state. As a result link speed does not change.
- The I350 does not initiate configuration of the PHY to avoid losing link.

The *keep\_PHY\_link\_up* bit is set by the BMC through the Management Control command (refer to [Section 10.5.10.1.5](#) for SMBus command and [Section 10.6.3.10](#) for NC-SI command) on the sideband interface. It is cleared by the external BMC (again, through a command on the sideband interface) when the manageability session ends. Once the *keep\_PHY\_link\_up* bit is cleared, the PHY updates its Dx state and acts accordingly (e.g. negotiates its speed).

The *Keep\_PHY\_Link\_Up* bit is also cleared on de-assertion of the MAIN\_PWR\_OK input pin. MAIN\_PWR\_OK must be de-asserted at least 1 msec before power drops below its 90% value. This allows enough time to respond before auxiliary power takes over.

The *Keep\_PHY\_Link\_Up* bit is a R/W bit and can be accessed by host software, but software is not expected to clear the bit. The bit is cleared in the following cases:

- On LAN Power Good
- When the BMC resets or initializes it
- On de-assertion of the MAIN\_PWR\_OK input pin. The BMC should set the bit again if it wishes to maintain speed on exit from Dr state.

## 4.4 Function Disable

### 4.4.1 General

For a LOM (Lan on Motherboard) design, it might be desirable for the system to provide BIOS-setup capability for selectively enabling or disabling LAN functions. It allows the end-user more control over system resource-management and avoid conflicts with add-in NIC solutions. The I350 provides support for selectively enabling or disabling one or more LAN device(s) in the system.

### 4.4.2 Overview

Device presence (or non-presence) must be established early during BIOS execution, in order to ensure that BIOS resource-allocation (of interrupts, of memory or IO regions) is done according to devices that are present only. This is frequently accomplished using a BIOS CVDR (Configuration Values Driven on Reset) mechanism. The I350 LAN-disable mechanism is implemented in order to be compatible with such a solution.

### 4.4.3 Disabling Both LAN Port and PCIe Function

The I350 provides two mechanisms to disable its LAN ports and the PCIe functions they reside on:

1. Four pins (LANx\_DIS\_N, one per LAN port) are sampled on PCIe reset to determine the LAN-enable configuration. If the relevant LANx\_DIS\_N is asserted and the *PHY\_in\_LAN\_Disable* EEPROM bit (refer to [Section 6.2.21](#)) associated with it is set to 1b, both the PCIe function and the LAN port associated with it are disabled.
  - The LANx\_DIS\_N pins are sampled on power-up, de-assertion of PE\_RST\_N or In-band PCIe reset.
  - Active polarity (active high or active low) of the LANx\_DIS\_N pins can be set via the *LAN\_DIS\_POL* EEPROM bit (refer to [Section 6.2.28](#)).
2. All LAN ports except the first (LAN Port 0) might be disabled via the *LAN\_DIS* EEPROM bit associated with the LAN port (refer to [Section 6.2.21](#)). LAN port 0 can not be disabled via the EEPROM to avoid cases where all LAN ports are disabled in the EEPROM resulting in a EEPROM that can't be accessed.

### 4.4.4 Disabling PCIe Function Only

The I350 supports also disabling just the PCIe function but keeping the LAN port that resides on it fully active (for manageability purposes and BMC pass-through traffic). This functionality can be achieved in three ways:

1. By setting the *LAN\_PCI\_DIS* EEPROM bit (refer to [Section 6.2.21](#)) associated with the PCIe function.
2. By asserting the relevant LANx\_DIS\_N pin and clearing the *PHY\_in\_LAN\_Disable* EEPROM bit (refer to [Section 6.2.21](#)).
  - Active polarity (active high or active low) of the LANx\_DIS\_N pins can be set via the *LAN\_DIS\_POL* EEPROM bit (refer to [Section 6.2.28](#)).
  - The LANx\_DIS\_N pins are sampled on de-assertion of PE\_RST\_N or In-band PCIe reset.
  - The LANx\_DIS\_N pins have an internal weak pull-up resistor. If the *LAN\_DIS\_POL* EEPROM bit (refer to [Section 6.2.28](#)) is cleared to 0b and a pin is not connected or driven high during init time, LAN 0 is enabled.
3. By asserting the relevant SDPx\_1 pin (SDP0\_1, SDP1\_1, SDP2\_1 or SDP3\_1 pins to disable PCIe Functions 0, 1, 2, and 3 respectively) when the *en\_pin\_pcie\_func\_dis* EEPROM bit (refer to [Section 6.2.28](#)) is set to 1b.
  - The SDPx\_1 pins are sampled on de-assertion of PE\_RST\_N or In-band PCIe reset.
  - Active polarity (active high or active low) of the SDPx\_1 pins can be set via the *PCI\_DIS\_POL* EEPROM bit (refer to [Section 6.2.28](#)).

**Note:** In this case when only the PCIe function is disabled, if the *PHPM.LPLU* register bit is set to 1b, the internal copper PHY associated with the disabled PCIe function will attempt to create a link with its link partner at the lowest common link speed via Auto-negotiation.

### 4.4.5 PCIe Functions to LAN Ports Mapping

When PCIe function 0 is disabled (Could be either associated with LAN0 or LAN3 as a function of the *FACTPS.LAN Function Sel* bit), two different behaviors are possible. The behavior is controlled by the *Dummy Function Enable* EEPROM bit (refer to [Section 6.2.17](#)):

1. Dummy Function mode — In some systems, it is required to keep all the functions at their respective location, even when other functions are disabled. In Dummy Function mode, if PCIe function 0 (either associated with LAN0 or LAN3) is disabled, then it does not disappear from the PCIe configuration space. Rather, the function presents itself as a dummy function. The device ID and class code of this function changes to other values (dummy function Device ID 0x10A6, Class Code 0xFF0000). In addition, the function does not require any memory or I/O space, and does not require an interrupt line.
2. Legacy mode - when PCIe function 0 is disabled, then the LAN port residing on the next existing PCIe function moves to reside on function 0. All other LAN ports keeps their respective locations.

**Note:** In some systems, the dummy function is not recognized by the enumeration process as a valid PCIe function. In these systems, all ports will not be enumerated and it is recommended to work in legacy mode.

PCIe function mapping to LAN ports as a function of disabled LAN ports and PCIe functions and the *FACTPS.LAN Function Sel* bit is summarized in the following tables.

**Notes:** PCIe Functions Mapping of the I350 dual port SKU behaves like the quad port SKU with Port 2 and Port 3 disabled.

In the Following tables a port is considered enabled if both the PCIe function and the LAN port is enabled.

**Table 4-5 PCI Functions Mapping (Legacy Mode)**

| Port 0 enabled | Port 1 enabled | Port 2 enabled | Port 3 enabled | FACTPS.LAN Function Sel | Function 0                                                                               | Function 1          | Function 2          | Function 3        |
|----------------|----------------|----------------|----------------|-------------------------|------------------------------------------------------------------------------------------|---------------------|---------------------|-------------------|
| Yes            | Yes            | Yes            | Yes            | 0                       | Port 0                                                                                   | Port 1              | Port 2              | Port 3            |
| Yes            | X              | X              | X              | 0                       | Port 0                                                                                   | As above if enabled |                     |                   |
| No             | Yes            | X              | X              | 0                       | Port 1                                                                                   | Disabled            | As above if enabled |                   |
| No             | No             | Yes            | X              | 0                       | Port 2                                                                                   | Disabled            | Disabled            | Port 3 if enabled |
| No             | No             | No             | Yes            | 0                       | Port 3                                                                                   | Disabled            | Disabled            | Disabled          |
| Yes            | Yes            | Yes            | Yes            | 1                       | Port 3                                                                                   | Port 2              | Port 1              | Port 0            |
| X              | X              | X              | Yes            | 1                       | Port 3                                                                                   | As above if enabled |                     |                   |
| X              | X              | Yes            | No             | 1                       | Port 2                                                                                   | Disabled            | As above if enabled |                   |
| X              | Yes            | No             | No             | 1                       | Port 1                                                                                   | Disabled            | Disabled            | Port 0 if enabled |
| Yes            | No             | No             | No             | 1                       | Port 0                                                                                   | Disabled            | Disabled            | Disabled          |
| No             | No             | No             | No             | X                       | All PCI functions are disabled. Device is in low power mode unless used by manageability |                     |                     |                   |

The following EEPROM bits control Function Disable:

- PCIe functions 1 to 3 can be enabled or disabled according to the *LAN\_PCI\_DIS* EEPROM bit (refer to [Section 6.2.21](#)).
  - PCIe function 0 can not be disabled via EEPROM.
- The *LAN\_DIS* EEPROM bit (refer to [Section 6.2.21](#)), indicates which function and LAN port are disabled. When this bit is set port is not available also to the manageability channel.
  - PCIe function 0 and the LAN port associated with it can not be disabled via EEPROM.
- The *LAN Function Sel* EEPROM bit (refer to [Section 6.2.22](#)), defines the correspondence between LAN Port and PCIe function.

- The *Dummy Function Enable* EEPROM bit (refer to [Section 6.2.17](#)) enables the Dummy Function mode for function 0. Default value is disabled.
- The *PHY\_in\_LAN\_disable* EEPROM bit (refer to [Section 6.2.21](#)), controls the availability of the disabled function to the manageability channel.
- The *en\_pin\_pcie\_func\_dis* EEPROM bit (refer to [Section 6.2.28](#)), controls whether asserting SDPx\_1 pins (SDP0\_1, SDP1\_1, SDP2\_1 or SDP3\_1 pins for PCIe Functions 0, 1, 2, and 3 respectively) during PCIe reset disables the relevant PCIe function.
- Polarity (Active low or Active high) of the SDPx\_1 pins can be set via the *PCI\_DIS\_POL* EEPROM bit (refer to [Section 6.2.28](#)).
- Polarity (Active Low or Active High) of the LANx\_DIS\_N pins can be set by the EEPROM via the *LAN\_DIS\_POL* EEPROM bit (refer to [Section 6.2.28](#)).

When a particular LAN is fully disabled, all internal clocks to that LAN are disabled, the device is held in reset, and the internal PHY for that LAN is powered-down. In both modes, the device does not respond to PCI configuration cycles. Effectively, the LAN device becomes invisible to the system from both a configuration and power-consumption standpoint.

## 4.4.6 Control Options

The functions have a separate enabling Mechanism. Any function that is not enabled does not function and does not expose its PCI configuration registers.

**Table 4-6 Strapping for Control Options**

| Function | Control Options                                                                                                                                                                                                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LAN 0    | Strapping Option + EEPROM bits <i>PHY_in_LAN_disable</i> (full/PCI only disable in case of LANx_DIS_N strap), <i>en_pin_pcie_func_dis</i> (Enable SDPx_1 strap), <i>LAN_DIS_POL</i> (LANx_DIS_N active polarity) and <i>PCI_DIS_POL</i> (SDPx_1 pin active polarity)                                                                                 |
| LAN 1    | Strapping Option + EEPROM bits <i>PHY_in_LAN_disable</i> (full/PCI only disable in case of LANx_DIS_N strap), <i>LAN_DIS</i> (full disable), <i>LAN_PCI_DIS</i> (PCIe Function only disable), <i>en_pin_pcie_func_dis</i> (Enable SDPx_1 strap), <i>LAN_DIS_POL</i> (LANx_DIS_N active polarity) and <i>PCI_DIS_POL</i> (SDPx_1 pin active polarity) |
| LAN 2    | Strapping Option + EEPROM bits <i>PHY_in_LAN_disable</i> (full/PCI only disable in case of LANx_DIS_N strap), <i>LAN_DIS</i> (full disable), <i>LAN_PCI_DIS</i> (PCIe Function only disable), <i>en_pin_pcie_func_dis</i> (Enable SDPx_1 strap), <i>LAN_DIS_POL</i> (LANx_DIS_N active polarity) and <i>PCI_DIS_POL</i> (SDPx_1 pin active polarity) |
| LAN 3    | Strapping Option + EEPROM bits <i>PHY_in_LAN_disable</i> (full/PCI only disable in case of LANx_DIS_N strap), <i>LAN_DIS</i> (full disable), <i>LAN_PCI_DIS</i> (PCIe Function only disable), <i>en_pin_pcie_func_dis</i> (Enable SDPx_1 strap), <i>LAN_DIS_POL</i> (LANx_DIS_N active polarity) and <i>PCI_DIS_POL</i> (SDPx_1 pin active polarity) |

The I350 strapping option for LAN Disable feature are:

**Table 4-7 Strapping for LAN Disable**

| Symbol     | Ball # | Name and Function                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LAN0_DIS_N |        | This pin is a strapping option pin always active. In case this pin is asserted during init time, LAN 0 is disabled. This pin is also used for testing and scan. When used for testing or scan, the LAN disable functionality is not active. Refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> for additional information.                                                                                        |
| LAN1_DIS_N |        | This pin is a strapping option pin always active. In case this pin is asserted during init time, LAN 1 function is disabled. This pin is also used for testing and scan. When used for testing or scan, the LAN disable functionality is not active. Refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> for additional information.                                                                               |
| LAN2_DIS_N |        | This pin is a strapping option pin always active. In case this pin is asserted during init time, LAN 2 is disabled. This pin is also used for testing and scan. When used for testing or scan, the LAN disable functionality is not active. Refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> for additional information.                                                                                        |
| LAN3_DIS_N |        | This pin is a strapping option pin always active. In case this pin is asserted during init time, LAN 3 is disabled. This pin is also used for testing and scan. When used for testing or scan, the LAN disable functionality is not active. Refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> for additional information.                                                                                        |
| SDP0_1     |        | This pin is a strapping option if the <i>en_pin_pcie_func_dis</i> EEPROM bit is set to 1b.<br>In case this pin is asserted during init time, PCIe function 0 is disabled. This pin is also used for testing and scan. When used for testing or scan or when the <i>en_pin_pcie_func_dis</i> EEPROM bit is 0b, the PCIe function disable functionality is not active. Refer to <a href="#">Section 4.4.4</a> for additional information. |
| SDP1_1     |        | This pin is a strapping option if the <i>en_pin_pcie_func_dis</i> EEPROM bit is set to 1b.<br>In case this pin is asserted during init time, PCIe function 1 is disabled. Refer to <a href="#">Section 4.4.4</a> for additional information. |
| SDP2_1     |        | This pin is a strapping option if the <i>en_pin_pcie_func_dis</i> EEPROM bit is set to 1b.<br>In case this pin is asserted during init time, PCIe function 2 is disabled. This pin is also used for testing and scan. When used for testing or scan or when the <i>en_pin_pcie_func_dis</i> EEPROM bit is 0b, the PCIe function disable functionality is not active. Refer to <a href="#">Section 4.4.4</a> for additional information. |
| SDP3_1     |        | This pin is a strapping option if the <i>en_pin_pcie_func_dis</i> EEPROM bit is set to 1b.<br>In case this pin is asserted during init time, PCIe function 3 is disabled. This pin is also used for testing and scan. When used for testing or scan or when the <i>en_pin_pcie_func_dis</i> EEPROM bit is 0b, the PCIe function disable functionality is not active. Refer to <a href="#">Section 4.4.4</a> for additional information. |

## 4.4.7 Event Flow for Enable/Disable Functions

This section describes the driving levels and event sequence for device functionality. Following a Power on Reset / LAN\_PWR\_GOOD / PE\_RST\_N/ In-Band reset the LANx\_DIS\_N pins and the SDPx\_1 pins (when the *en\_pin\_pcie\_func\_dis* EEPROM bit is set) should be de-asserted for nominal operation. If any of the LAN functions are not required statically its associated Disable strapping pin can be tied statically to low.

Case A - BIOS Disables the LAN Function at boot time by using strapping:

1. Assume that following power up the LANx\_DIS\_N pins and the SDPx\_1 pins are de-asserted.
2. The PCIe link is established following the PE\_RST\_N.
3. BIOS recognizes that a LAN function in the I350 should be disabled.
4. The BIOS asserts the LANx\_DIS\_N pin or SDPx\_1 pin.
5. The BIOS should assert the PCIe reset, either in-band or via PE\_RST\_N.

6. As a result, the I350 samples the LANx\_DIS\_N and SDPx\_1 pins, disables the LAN function and issues an internal reset to the disabled function.
7. BIOS might start with the Device enumeration procedure (the disabled LAN function is invisible or changed to dummy function).
8. Proceed with Nominal operation.
9. Re-enable of the function could be done by de-asserting the LANx\_DIS\_N pin or SDPx\_1 pin and then request the user to issue a warm boot that causes bus enumeration.

#### 4.4.7.1 Multi-Function Advertisement

If all but one of the LAN devices are disabled, the I350 is no longer a multi-function device. The I350 normally reports a 0x80 in the PCI Configuration Header field Header Type, indicating multi-function capability. However, if only a single LAN is enabled, the I350 reports a 0x0 in this field to signify single-function capability.

#### 4.4.7.2 Legacy Interrupts Utilization

When more than one LAN device is enabled, the I350 can utilize the INTA# to INTC# interrupts for interrupt reporting. The EEPROM *Initialization Control Word 3* (bits 12:11) associated with each LAN device controls which of these interrupts are used for each LAN device. The specific interrupt pin utilized is reported in the PCI Configuration Header Interrupt Pin field associated with each LAN device.

However, if only one LAN device is enabled, then the INTA# must be used for this LAN device, regardless of the EEPROM configuration. Under these circumstances, the Interrupt Pin field of the PCI Header always reports a value of 0x1, indicating INTA# usage.

#### 4.4.7.3 Power Reporting

When more than one LAN function is enabled, the PCI Power Management Register Block has the capability of reporting a "Common Power" value. The Common Power value is reflected in the Data field of the PCI Power Management registers. The value reported as Common Power is specified via the *LAN Power Consumption* EEPROM word (word 0x22), and is reflected in the Data field whenever the Data\_Select field has a value of 0x8 (0x8 = Common Power Value Select).

When only one LAN is enabled, the I350 appears as a single-function device, the Common Power value, if selected, reports 0x0 (undefined value), as Common Power is undefined for a single-function device.

### 4.5 Device Disable

For a LOM design, it might be desirable for the system to provide BIOS-setup capability for selectively enabling or disabling LOM devices. This might allow the end-user more control over system resource-management; avoid conflicts with add-in NIC solutions, etc. The I350 provides support for selectively enabling or disabling it.

**Note:** If the I350 is configured to provide a 50MHz NC-SI clock (via the NC-SI Output Clock EEPROM bit), then the device should not be disabled.

Device Disable is initiated by assertion of the asynchronous DEV\_OFF\_N pin. The DEV\_OFF\_N pin should always be connected to enable correct device operation.

The EEPROM *Power Down Enable* bit (refer to [Section 6.2.19](#)) enables device disable mode (Hardware default is that this mode is disabled) and the EEPROM bit *Deep DEV\_OFF* (refer to [Section 6.2.22](#)) defines amount of power saving when DEV\_OFF\_N is asserted.

While in device disable mode, the PCIe link is in L3 state. The PHY is in power down mode. Output buffers are tri-stated.

**Note:** Behavior of SDP pins in device disable mode is controlled by the *SDP\_IDDQ\_EN* EEPROM bit (refer to [Section 6.2.2](#)).

Assertion or deassertion of PCIe PE\_RST\_N does not have any affect while the device is in device disable mode (i.e., the device stays in the respective mode as long as DEV\_OFF\_N is asserted). However, the device might momentarily exit the device disable mode from the time PCIe PE\_RST\_N is de-asserted again and until the EEPROM is read.

During power-up, the DEV\_OFF\_N pin is ignored until the EEPROM is read. From that point, the device might enter Device Disable if DEV\_OFF\_N is asserted.

**Note:** De-assertion of the DEV\_OFF\_N pin causes a fundamental reset to the I350.

Note to system designer: The DEV\_OFF\_N pin should maintain its state during system reset and system sleep states. It should also insure the proper default value on system power-up. For example, one could use a GPIO pin that defaults to '1' (enable) and is on system suspend power (i.e., it maintains state in S0-S5 ACPI states).

## 4.5.1 BIOS Handling of Device Disable

1. Assume that following power up sequence the DEV\_OFF\_N signal is driven high (else it is already disabled).
2. The PCIe is established following the PE\_RST\_N.
3. BIOS recognize that the whole Device should be disabled.
4. The BIOS drive the DEV\_OFF\_N signal to the low level.
5. As a result, the I350 samples the DEV\_OFF\_N signal and enters the device disable mode.
6. The BIOS places the Link in the Electrical IDLE state (at the other end of the PCIe link) by clearing the LINK Disable bit in the Link Control Register.
7. BIOS might start with the Device enumeration procedure (all of the Device functions are invisible).
8. Proceed with Nominal operation.
9. Re-enable could be done by driving the DEV\_OFF\_N signal high followed later by bus enumeration.

## 4.6 Software Initialization and Diagnostics

### 4.6.1 Introduction

This chapter discusses general software notes for the I350, especially initialization steps. This includes general hardware, power-up state, basic device configuration, initialization of transmit and receive operation, link configuration, software reset capability, statistics, and diagnostic hints.

## 4.6.2 Power Up State

When the I350 powers up it reads the EEPROM. The EEPROM contains sufficient information to bring the link up and configure the I350 for manageability and/or APM wakeup. However, software initialization is required for normal operation.

The power-up sequence, as well as transitions between power states, are described in [Section 4.1.1](#). The detailed timing is given in [Section 5.5](#). The next section gives more details on configuration requirements.

## 4.6.3 Initialization Sequence

The following sequence of commands is typically issued to the device by the software device driver in order to initialize the I350 to normal operation. The major initialization steps are:

- Disable Interrupts - see Interrupts during initialization.
- Issue Global Reset and perform General Configuration - see Global Reset and General Configuration.
- Setup the PHY and the link - see Link Setup Mechanisms and Control/Status Bit Summary.
- Initialize all statistical counters - refer to [Section 4.6.8](#).
- Initialize Receive - refer to [Section 4.6.9](#).
- Initialize Transmit - refer to [Section 4.6.10](#).
- Enable Interrupts - refer to [Section 4.6.4](#).

## 4.6.4 Interrupts During Initialization

- Most drivers disable interrupts during initialization to prevent re-entering the interrupt routine. Interrupts are disabled by writing to the *EIMC* (Extended Interrupt Mask Clear) register. Note that the interrupts need to be disabled also after issuing a global reset, so a typical driver initialization flow is:
  - Disable interrupts
  - Issue a Global Reset
  - Disable interrupts (again)
  - ...

After the initialization is done, a typical driver enables the desired interrupts by writing to the *EIMS* (Extended Interrupt Mask Set) register.

## 4.6.5 Global Reset and General Configuration

Device initialization typically starts with a global reset that places the device into a known state and enables the device driver to continue the initialization sequence.

Several values in the Device Control Register (*CTRL*) need to be set, upon power up, or after a device reset for normal operation.

- *FD* bit should be set per interface negotiation (if done in software), or is set by the hardware if the interface is Auto-Negotiating. This is reflected in the *Device Status* Register in the Auto-Negotiation case.
- Speed is determined via Auto-Negotiation by the PHY, Auto-Negotiation by the PCS layer in SGMII/SerDes mode, or forced by software if the link is forced. Status information for speed is also readable in the *STATUS* register.
- *ILOS* bit should normally be set to 0.

## 4.6.6 Flow Control Setup

If flow control is enabled, program the *FCRTL0*, *FCRTH0*, *FCTTV* and *FCRTV* registers. In order to avoid packet losses, *FCRTH* should be set to a value equal to at least two max size packet below the receive buffer size. E.g. Assuming a packet buffer size of 36 KB and expected max size packet of 9.5K, the *FCRTH0* value should be set to  $36 - 2 * 9.5 = 17\text{KB}$  i.e. *FCRTH0.RTH* should be set to 0x440.

If DMA Coalescing is enabled, to avoid packet loss, the *FCRTC.RTH\_Coal* field should also be programmed to a value equal to at least a single max packet size below the receive buffer size (i.e. a value equal or less than *FCRTH0.RTH* + max size packet).

## 4.6.7 Link Setup Mechanisms and Control/Status Bit Summary

The *CTRL\_EXT.LINK\_MODE* value should be set to the desired mode prior to the setting of the other fields in the link setup procedures.

### 4.6.7.1 PHY Initialization

Refer to the PHY documentation for the initialization and link setup steps. The device driver uses the *MDIC* register to initialize the PHY and setup the link. [Section 3.7.4.4](#) describes the link setup for the internal copper PHY. [Section 3.7.2.2](#) Section describes the usage of the *MDIC* register.

### 4.6.7.2 MAC/PHY Link Setup (*CTRL\_EXT.LINK\_MODE* = 00b)

This section summarizes the various means of establishing proper MAC/PHY link setups, differences in MAC *CTRL* register settings for each mechanism, and the relevant MAC status bits. The methods are ordered in terms of preference (the first mechanism being the most preferred).

#### 4.6.7.2.1 MAC Settings Automatically Based on Duplex and Speed Resolved by PHY (*CTRL.FRCDPLX* = 0b, *CTRL.FRCDSPD* = 0b)

|                  |                                                                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>CTRL.FD</i>   | Don't care; duplex setting is established from PHY's internal indication to the MAC (FDX) after PHY has auto-negotiated a successful link-up. |
| <i>CTRL.SLU</i>  | Must be set to 1 by software to enable communications between MAC and PHY.                                                                    |
| <i>CTRL.RFCE</i> | Must be programmed by software after reading capabilities from PHY registers and resolving the desired flow control setting.                  |
| <i>CTRL.TFCE</i> | Must be programmed by software after reading capabilities from PHY registers and resolving the desired flow control setting.                  |

|                     |                                                                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>CTRL.SPEED</i>   | Don't care; speed setting is established from PHY's internal indication to the MAC ( <i>SPD_IND</i> ) after PHY has auto-negotiated a successful link-up. |
| <i>STATUS.FD</i>    | Reflects the actual duplex setting (FDX) negotiated by the PHY and indicated to MAC.                                                                      |
| <i>STATUS.LU</i>    | Reflects link indication (LINK) from PHY qualified with <i>CTRL.SLU</i> (set to 1).                                                                       |
| <i>STATUS.SPEED</i> | Reflects actual speed setting negotiated by the PHY and indicated to the MAC ( <i>SPD_IND</i> ).                                                          |

#### 4.6.7.2.2 MAC Duplex and Speed Settings Forced by Software Based on Resolution of PHY (*CTRL.FRCDPLX* = 1b, *CTRL.FRCSPD* = 1b)

|                     |                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------|
| <i>CTRL.FD</i>      | Set by software based on reading PHY status register after PHY has auto-negotiated a successful link-up.                     |
| <i>CTRL.SLU</i>     | Must be set to 1 by software to enable communications between MAC and PHY.                                                   |
| <i>CTRL.RFCE</i>    | Must be programmed by software after reading capabilities from PHY registers and resolving the desired flow control setting. |
| <i>CTRL.TFCE</i>    | Must be programmed by software after reading capabilities from PHY registers and resolving the desired flow control setting. |
| <i>CTRL.SPEED</i>   | Set by software based on reading PHY status register after PHY has auto-negotiated a successful link-up.                     |
| <i>STATUS.FD</i>    | Reflects the MAC forced duplex setting written to <i>CTRL.FD</i> .                                                           |
| <i>STATUS.LU</i>    | Reflects link indication (LINK) from PHY qualified with <i>CTRL.SLU</i> (set to 1).                                          |
| <i>STATUS.SPEED</i> | Reflects MAC forced speed setting written in <i>CTRL.SPEED</i> .                                                             |

#### 4.6.7.2.3 MAC/PHY Duplex and Speed Settings Both Forced by Software (Fully-Forced Link Setup) (*CTRL.FRCDPLX* = 1b, *CTRL.FRCSPD* = 1b, *CTRL.SLU* = 1b)

|                     |                                                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>CTRL.FD</i>      | Set by software to desired full/half duplex operation (must match duplex setting of PHY).                                                                                                                                                                     |
| <i>CTRL.SLU</i>     | Must be set to 1 by software to enable communications between MAC and PHY. PHY must also be forced/configured to indicate positive link indication (LINK) to the MAC.                                                                                         |
| <i>CTRL.RFCE</i>    | Must be programmed by software to desired flow-control operation (must match flow-control settings of PHY).                                                                                                                                                   |
| <i>CTRL.TFCE</i>    | Must be programmed by software to desired flow-control operation (must match flow-control settings of PHY).                                                                                                                                                   |
| <i>CTRL.SPEED</i>   | Set by software to desired link speed (must match speed setting of PHY).                                                                                                                                                                                      |
| <i>STATUS.FD</i>    | Reflects the MAC duplex setting written by software to <i>CTRL.FD</i> .                                                                                                                                                                                       |
| <i>STATUS.LU</i>    | Reflects 1 (positive link indication LINK) from PHY qualified with <i>CTRL.SLU</i> . Note that since both <i>CTRL.SLU</i> and the PHY link indication LINK are forced, this bit set does not guarantee that operation of the link has been truly established. |
| <i>STATUS.SPEED</i> | Reflects MAC forced speed setting written in <i>CTRL.SPEED</i> .                                                                                                                                                                                              |

### 4.6.7.3 MAC/SERDES Link Setup (CTRL\_EXT.LINK\_MODE = 11b)

Link setup procedures using an external SERDES interface mode:

#### 4.6.7.3.1 Hardware Auto-Negotiation Enabled (PCS\_LCTL.AN\_ENABLE = 1b; CTRL.FRCSPD = 0b; CTRL.FRCDPLX = 0)

|                                    |                                                                                                                                                                                                             |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>CTRL.FD</i>                     | Ignored; duplex is set by priority resolution of <i>PCS_ANDV</i> and <i>PCS_LPAB</i> .                                                                                                                      |
| <i>CTRL.SLU</i>                    | Must be set to 1 by software to enable communications to the SerDes.                                                                                                                                        |
| <i>CTRL.RFCE</i>                   | Set by Hardware according to auto negotiation resolution <sup>1</sup> .                                                                                                                                     |
| <i>CTRL.TFCE</i>                   | Set by Hardware according to auto negotiation resolution <sup>1</sup> .                                                                                                                                     |
| <i>CTRL.SPEED</i>                  | Ignored; speed always 1000Mb/s when using SerDes mode communications.                                                                                                                                       |
| <i>STATUS.FD</i>                   | Reflects hardware-negotiated priority resolution.                                                                                                                                                           |
| <i>STATUS.LU</i>                   | Reflects <i>PCS_LSTS.AN_COMPLETE</i> (Auto-Negotiation complete) and link is up.                                                                                                                            |
| <i>STATUS.SPEED</i>                | Reflects 1000Mb/s speed, reporting fixed value of (10)b.                                                                                                                                                    |
| <i>PCS_LCTL.FSD</i>                | Must be zero.                                                                                                                                                                                               |
| <i>PCS_LCTL.Force Flow Control</i> | Must be zero <sup>1</sup> .                                                                                                                                                                                 |
| <i>PCS_LCTL.FSV</i>                | Must be set to 10b. Only 1000 Mb/s is supported in SerDes mode.                                                                                                                                             |
| <i>PCS_LCTL.FDV</i>                | Ignored; duplex is set by priority resolution of <i>PCS_ANDV</i> and <i>PCS_LPAB</i> .                                                                                                                      |
| <i>PCS_LCTL.AN_TIMEOUT_EN</i>      | Must be 1b to enable Auto-negotiation time-out.                                                                                                                                                             |
| <i>CONNSW.ENRGSR</i>               | Must be 0b on 1000BASE-BX backplane, when source of the signal detect indication is internal. When connected to an optical module and <i>SRDS_[n]_SIG_DET</i> pin is connected to the module, should be 1b. |
| <i>CTRL.ILOS</i>                   | If <i>SRDS_[n]_SIG_DET</i> pin connected to optical module, should be set according to optical module polarity.                                                                                             |

#### 4.6.7.3.2 Auto-Negotiation Skipped (PCS\_LCTL.AN\_ENABLE = 0b; CTRL.FRCSPD = 1b; CTRL.FRCDPLX = 1)

|                     |                                                                                      |
|---------------------|--------------------------------------------------------------------------------------|
| <i>CTRL.FD</i>      | Must be set to 1b. - only full duplex is supported in SerDes mode.                   |
| <i>CTRL.SLU</i>     | Must be set to 1b by software to enable communications to the SerDes.                |
| <i>CTRL.RFCE</i>    | Must be 0b (No Auto-negotiation).                                                    |
| <i>CTRL.TFCE</i>    | Must be 0b (No Auto-negotiation).                                                    |
| <i>CTRL.SPEED</i>   | Must be set to 10b. Only 1000 Mb/s is supported in SerDes mode.                      |
| <i>STATUS.FD</i>    | Reflects the value written by software to <i>CTRL.FD</i> .                           |
| <i>STATUS.LU</i>    | Reflects whether the PCS is synchronized, qualified with <i>CTRL.SLU</i> (set to 1). |
| <i>STATUS.SPEED</i> | Reflects 1000Mb/s speed, reporting fixed value of (10)b.                             |
| <i>PCS_LCTL.FSD</i> | Must be set to 1b by software to enable communications to the SerDes.                |

1. If *PCS\_LCTL.Force Flow Control* is set, the auto negotiation result is not reflected in the *CTRL.RFCE* and *CTRL.TFCE* registers. In This case, the software must set these fields after reading flow control resolution from PCS registers.

*PCS\_LCTL.Force Flow Control*

Must be set to 1b.

*PCS\_LCTL.FSV*

Must be set to 10b. Only 1000 Mb/s is supported in SerDes mode.

*PCS\_LCTL.FDV*

Must be set to 1b - only full duplex is supported in SerDes mode.

*PCS\_LCTL.AN TIMEOUT EN*

Must be 0b when Auto-negotiation is disabled.

*CONNSW.ENRGSR*

Must be 0b on 1000BASE-BX backplane, when source of the signal detect indication is internal. When connected to an optical module and SRDS\_[n]\_SIG\_DET pin is connected to the module, should be 1b.

*CTRL.ILOS*

If SRDS\_[n]\_SIG\_DET pin connected to optical module, should be set according to optical module polarity.

#### 4.6.7.4 MAC/SGMII Link Setup (CTRL\_EXT.LINK\_MODE = 10b)

Link setup procedures using an external SGMII interface mode:

##### 4.6.7.4.1 Hardware Auto-Negotiation Enabled (PCS\_LCTL.AN ENABLE = 1b, CTRL.FRCPLX = 0b, CTRL.FRCSPD = 0b)

*CTRL.FD*

Ignored; duplex is set by priority resolution of PCS\_ANDV and PCS\_LPAB.

*CTRL.SLU*

Must be set to 1 by software to enable communications to the SerDes.

*CTRL.RFCE*

Must be programmed by software after reading capabilities from external PHY registers and resolving the desired setting.

*CTRL.TFCE*

Must be programmed by software after reading capabilities from external PHY registers and resolving the desired setting.

*CTRL.SPEED*

Ignored; speed setting is established from SGMII's internal indication to the MAC after SGMII PHY has auto-negotiated a successful link-up.

*STATUS.FD*

Reflects hardware-negotiated priority resolution.

*STATUS.LU*

Reflects PCS\_LSTS.Link OK

*STATUS.SPEED*

Reflects actual speed setting negotiated by the SGMII and indicated to the MAC.

*PCS\_LCTL.Force Flow Control*

Ignored.

*PCS\_LCTL.FSD*

Should be set to zero.

*PCS\_LCTL.FSV*

Ignored; speed is set by priority resolution of PCS\_ANDV and PCS\_LPAB.

*PCS\_LCTL.FDV*

Ignored; duplex is set by priority resolution of PCS\_ANDV and PCS\_LPAB.

*PCS\_LCTL.AN TIMEOUT EN*

Must be 0b. Auto-negotiation time-out should be disabled in SGMII mode.

*CONNSW.ENRGSR*

Must be 0b. In SGMII mode source of the signal detect indication is internal.

#### 4.6.7.5 MAC/1000BASE-KX Link Setup (CTRL\_EXT.LINK\_MODE = 01b)

##### 4.6.7.5.1 Auto-Negotiation Skipped (PCS\_LCTL.AN ENABLE = 0b; CTRL.FRCSPD = 1b; CTRL.FRCPLX = 1)

Link setup procedures using an external 1000BASE-KX Server Backplane interface mode:

|                                    |                                                                                       |
|------------------------------------|---------------------------------------------------------------------------------------|
| <i>CTRL.FD</i>                     | Must be set to 1b. 1000BASE-KX always in full duplex mode.                            |
| <i>CTRL.SLU</i>                    | Must be set to 1b by software to enable communications to the SerDes.                 |
| <i>CTRL.RFCE</i>                   | Must be 0b (no Auto-negotiation).                                                     |
| <i>CTRL.TFCE</i>                   | Must be 0b (no Auto-negotiation).                                                     |
| <i>CTRL.SPEED</i>                  | Must be set to 10b. Only 1000 Mb/s is supported in 1000BASE-KX mode.                  |
| <i>STATUS.FD</i>                   | Reflects the value written by software to <i>CTRL.FD</i> .                            |
| <i>STATUS.LU</i>                   | Reflects whether the PCS is synchronized, qualified with <i>CTRL.SLU</i> (set to 1b). |
| <i>STATUS.SPEED</i>                | Reflects 1000Mb/s speed, reporting fixed value of (10b).                              |
| <i>PCS_LCTL.FSD</i>                | Must be set to 1b by software to enable communications to the 1000BASE-KX SerDes.     |
| <i>PCS_LCTL.Force Flow Control</i> | Must be set to 1b.                                                                    |
| <i>PCS_LCTL.FSV</i>                | Must be set to 10b. Only 1000 Mb/s is supported in 1000BASE-KX mode.                  |
| <i>PCS_LCTL.FDV</i>                | Must be set to 1b - only full duplex is supported in 1000BASE-KX mode.                |
| <i>PCS_LCTL.AN TIMEOUT EN</i>      | Must be 0b. Auto-negotiation not supported in 1000BASE-KX mode.                       |
| <i>CONNSW.ENRGSR</i>               | Must be 0b. In 1000BASE-KX mode source of the signal detect indication is internal.   |

## 4.6.8 Initialization of Statistics

Statistics registers are hardware-initialized to values as detailed in each particular register's description. The initialization of these registers begins upon transition to D0active power state (when internal registers become accessible, as enabled by setting the Memory Access Enable of the PCIe Command register), and is guaranteed to be completed within 1  $\mu$ sec of this transition. Access to statistics registers prior to this interval might return indeterminate values.

All of the statistical counters are cleared on read and a typical device driver reads them (thus making them zero) as a part of the initialization sequence.

## 4.6.9 Receive Initialization

Program the Receive address register(s) per the station address. This can come from the EEPROM or by any other means (for example, on some machines, this comes from the system PROM not the EEPROM on the adapter card).

Set up the MTA (Multicast Table Array) by software. This means zeroing all entries initially and adding in entries as requested.

Program *RCTL* with appropriate values. If initializing it at this stage, it is best to leave the receive logic disabled (*RCTL.RXEN* = 0b) until after the receive descriptor rings have been initialized. If VLANs are not used, software should clear *VFE*. Then there is no need to initialize the *VFTA*. Select the receive descriptor type.

The following should be done once per receive queue needed:

1. Allocate a region of memory for the receive descriptor list.
2. Receive buffers of appropriate size should be allocated and pointers to these buffers should be stored in the descriptor ring.
3. Program the descriptor base address with the address of the region.
4. Set the length register to the size of the descriptor ring.
5. Program *SRRCTL* of the queue according to the size of the buffers, the required header handling and the drop policy.
6. If header split or header replication is required for this queue, program the *PSRTYPE* register according to the required headers.
7. Enable the queue by setting *RXDCTL.ENABLE*. In the case of queue zero, the enable bit is set by default - so the ring parameters should be set before *RCTL.RXEN* is set.
8. Poll the *RXDCTL* register until the *ENABLE* bit is set. The tail should not be bumped before this bit was read as one.
9. Program the direction of packets to this queue according to the mode selected in the *MRQC* register. Packets directed to a disabled queue are dropped.

**Note:** The tail register of the queue (*RD[n]*) should not be bumped until the queue is enabled.

#### 4.6.9.1 Initialize the Receive Control Register

To properly receive packets the receiver should be enabled by setting *RCTL.RXEN*. This should be done only after all other setup is accomplished. If software uses the Receive Descriptor Minimum Threshold Interrupt, that value should be set.

#### 4.6.9.2 Dynamic Enabling and Disabling of Receive Queues

Receive queues can be dynamically enabled or disabled given the following procedure is followed:

##### Enabling a queue:

- Follow the per queue initialization sequence described in [Section 4.6.9](#).

**Note:** If there are still packets in the packet buffer assigned to this queue according to previous settings, they are received after the queue is re-enabled. In order to avoid this condition, the software might poll the *PBRWAC* register. Once an empty condition of the relevant packet buffer is detected or 2 wrap around occurrences are detected the queue can be re-enabled.

##### Disabling a queue:

1. Disable assignment of packets to this queue.
2. Clear the *VFRE* bit allocated to the queue in the *VFRE* register.
3. Poll the *PBRWAC* register until an empty condition of the relevant packet buffer is detected or 2 wrap around occurrences are detected.
4. Disable the queue by clearing *RXDCTL.ENABLE*. The I350 stops fetching and writing back descriptors from this queue immediately. The I350 eventually completes the storage of one buffer allocated to this queue. Any further packet directed to this queue is dropped. If the currently processed packet is spread over more than one buffer, all subsequent buffers are not written.
5. The I350 clears *RXDCTL.ENABLE* only after all pending memory accesses to the descriptor ring or to the buffers are done. The driver should poll this bit before releasing the memory allocated to this queue.
6. Set the *VFRE* bit allocated to the queue so that the queue can be re-enabled.

**Note:** The RX path can be disabled only after all Rx queues are disabled.

## 4.6.10 Transmit Initialization

- Program the *TCTL* register according to the MAC behavior needed.

If work in half duplex mode is expected, program the *TCTL\_EXT.COLD* field. For internal PHY mode the default value of 0x42 is OK. For SGMII mode, a value reflecting the I350 and the PHY SGMII delays should be used. A suggested value for a typical PHY is 0x46 for 10 Mbps and 0x4C for 100 Mbps.

The following should be done once per transmit queue:

- Allocate a region of memory for the transmit descriptor list.
- Program the descriptor base address with the address of the region.
- Set the length register to the size of the descriptor ring.
- Program the *TXDCTL* register with the desired TX descriptor write back policy. Suggested values are:
  - *WTHRESH* = 1b
  - All other fields 0b.
- If needed, set the *TDWBAL/TWDBAH* to enable head write back
- Enable the queue using *TXDCTL.ENABLE* (queue zero is enabled by default).
- Poll the *TXDCTL* register until the *ENABLE* bit is set.

**Note:** The tail register of the queue (*TDT[n]*) should not be bumped until the queue is enabled.

Enable transmit path by setting *TCTL.EN*. This should be done only after all other settings are done.

### 4.6.10.1 Dynamic Queue Enabling and Disabling

Transmit queues can be dynamically enabled or disabled given the following procedure is followed:

#### Enabling:

- Follow the per queue initialization described in the previous section.

#### Disabling:

- Stop storing packets for transmission in this queue.
- Wait until the head of the queue (*TDH*) is equal to the tail (*TDT*), i.e. the queue is empty.
- Disable the queue by clearing *TXDCTL.ENABLE*.

The Tx path might be disabled only after all Tx queues are disabled.

## 4.6.11 Virtualization Initialization Flow

### 4.6.11.1 VMDq Mode

#### 4.6.11.1.1 Global Filtering and Offload Capabilities

- Select the VMDQ pooling method - MAC/VLAN filtering for pool selection. *MRQC.Multiple Receive Queues Enable* = 011b.
- Set the *RPLPSRTYPE* registers to define the behavior of replicated packets.
- Configure *VT\_CTL.DEF\_PL* to define the default pool. If packets with no pools should be dropped, set *VT\_CTL.Dis\_def\_Pool* field.
- If needed, enable padding of small packets via the *RCTL.PSP*

#### 4.6.11.1.2 Mirroring rules.

For each mirroring rule to be activated:

- Set the type of traffic to be mirrored in the *VMRCTL[n]* register.
- Set the mirror pool in the *VMRCTL[n].MP*
- For pool mirroring, set the *VMRVM[n]* register with the pools to be mirrored.
- For VLAN mirroring, set the *VMVLAN[n]* with the indexes from the *VLVF* registers of the VLANs to be mirrored.

#### 4.6.11.1.3 Per Pool Settings

As soon as a pool of queues is associated to a VM the software should set the following parameters:

- Address filtering:
  - The unicast MAC address of the VM by enabling the pool in the *RAH/RAL* registers.
  - If all the MAC addresses are used, the unicast hash table (*UTA*) can be used. Pools servicing VMs whose address is in the hash table should be declared as so by setting the *VMOLR.ROPE*. Packets received according to this method didn't pass perfect filtering and are indicated as such.
  - Enable the pool in all the *RAH/RAL* registers representing the multicast MAC addresses this VM belongs to.
  - If all the MAC addresses are used, the multicast hash table (*MTA*) can be used. Pools servicing VMs using multicast addresses in the hash table should be declared as so by setting the *VMOLR.ROMPE*. Packets received according to this method didn't pass perfect filtering and are indicated as such.
  - Define whether this VM should get all multicast/broadcast packets in the same VLAN via the *VMOLR.MPE* and *VMOLR.BAM* fields
  - Enable the pool in each *VLVF* register representing a VLAN this VM belongs to.
  - Define whether the pool belongs to the default VLAN and should accept untagged packets via the *VMOLR.AUPE* field
- Offloads
  - Define whether VLAN header should be stripped from the packet (defined by *DVMOLR.strvlan*).
  - Set which header split is required via the *PSRTYPE* register.
  - Set whether larger than standard packet are allowed by the VM and what is the largest packet allowed (jumbo packets support) via the *VMOLR.RLPML* and *VMOLR.RLE* fields.
- Queues
  - Enable Rx and Tx queues as described in [Section 4.6.9](#) and [Section 4.6.10](#)
  - For each Rx queue a drop/no drop flag can be set in *SRRCTL.DROP\_EN* or via the QDE register, controlling the behavior in cases no receive buffers are available in the queue to receive packets. The usual behavior is to allow drops in order to avoid head of line blocking, unless a no-drop behavior is needed for some type of traffic (e.g. storage).

#### 4.6.11.1.4 Security Features

##### 4.6.11.1.4.1 Storm control

The driver may set limits to the broadcast or multicast traffic it can receive.

1. It should set the how many 64 byte chunks of Broadcast and Multicast traffic are acceptable per interval via the *BSCTRH* and *MSCTRH* respectively.
2. It should then set the interval to be used via the *SCCRL.Interval* field and which action to take when the broadcast or multicast traffic crosses the programmed threshold via the *SCCRL.BDIPW*, *SCCRL.BDICW*, *SCCRL.MDIPW*, and *SCCRL.MDICW* fields.
3. The driver may be notified of storm control events through the *ICR.SCE* interrupt cause.

#### 4.6.11.2 IOV Initialization

The initialization flow used to enable an IOV function can be found in chapter 2 of the PCI-Express Single Root I/O Virtualization and Sharing Specification.

##### 4.6.11.2.1 PF Driver Initialization

The PF driver is responsible for the link setup and handling of all the filtering & off load capabilities for all the VFs as described in [Section 4.6.11.1.1](#) and the security features as described in [Section 4.6.11.1.4](#). It should also set the bandwidth allocation per transmit queue for each VF as described in [Section 4.6.10](#).

After all the common parameters are set, the PF driver should set all the *VFMailbox.RSTD* bit by setting the *CTRL.PFRSTD*.

The PF might disable all the active VFs traffic via the *VFTE* & *VFRE* registers until the parameters of a VF are set as defined in [Section 4.6.11.1.3](#), the VF can be enabled using the same registers.

##### 4.6.11.2.1.1 VF Specific Reset Coordination

After the PF driver receives an indication of a VF FLR via the *VFLRE* register, it should enable the receive and transmit for the VF only once the device is programmed with the right parameters as defined in [Section 4.6.11.1.3](#). The receive filtering is enabled using the *VFRE* register and the transmit filtering is enabled via the *VFTE* register.

**Note:** The filtering and offloads setup might be based on a central IT settings or on requests from the VF drivers.

The PF driver should assert the VF reset via the *VTCTRL* register before configuration of the VF parameters.

##### 4.6.11.2.2 VF Driver Initialization

Upon init, after the PF indicated that the global init was done via the *VFMailbox.RSTD* bit, the VF driver should communicate with the PF, either via the mailbox or other software mechanisms to assure that the right parameters of the VF are programmed as described in [Section 4.6.11.1.3](#).

The mailbox mechanism is described in [Section 7.8.2.9.1](#).

The PF should also setup the security measures as described in [Section 4.6.11.1.4](#). In addition, the PF may also program whether the VF is allowed to control VLAN insertion or whether VLAN insertion is controlled by the PF via the relevant *VMVIR* register.

The PF should initialize all the statistical counters described in [Section 8.18.77](#) to zero.

The PF driver might then send an acknowledge message with the actual setup done according to the VF request and the IT policy.

The VF driver should then setup the interrupts and the queues as described in [Section 4.6.9](#) & [Section 4.6.10](#).

### 4.6.11.2.3 Full Reset Coordination

A mechanism is provided to synchronize reset procedures between the Physical Function and the VFs. It is provided specifically for PF software reset but can be used in other reset cases as described below.

The procedure is as follows:

When one of the following reset cases occurs:

- LAN\_PWR\_GOOD
- PCIe Reset (PE\_RST\_N or in-band PCIe reset)
- D3hot --> D0
- FLR
- Software reset by the PF (*CTRL.RST*)
- Device Reset by PF (*CTRL.DEV\_RST*)

The I350 sets the *RSTI* bits in all the *VFMailbox* registers. Once the reset completes, each VF might read its *VFMailbox* register to identify a reset in progress.

Once the PF completed configuring the device, it sets the *CTRL\_EXT.PFRSTD* bit. As a result, the I350 clears the *RSTI* bits in all the *VFMailbox* registers and sets the *RSTD* (Reset Done) bits in all the *VFMailbox* registers.

Until a *VFMailbox.RSTD* condition is detected, the VFs should access only the *VFMailbox* register and should not attempt to activate the interrupt mechanism or the transmit and receive process.

**Note:** Before issuing a software reset (*CTRL.RST* or *CTRL.DEV\_RST*) the PF driver should send a mailbox message to the various VFs via the mailbox mechanism described in [Section 7.8.2.9.1](#) to indicate that a reset is going to occur, following acknowledgment of the message by all the VFs the PF driver can issue the software reset.

### 4.6.11.2.4 VFRE/VFTE

This mechanism insures that a VF cannot transmit or receive before the Tx and Rx path have been initialized by the PF. It is required for VFLR reset and must also be used in case of VF software reset. It is optional for PF software reset as described above. The VFRE register contains a bit per VF. When the bit is cleared assignment of Rx packet for the VF's pool is disabled. When set, assignment of Rx packet for the VF's pool is enabled.

The VFTE register contains a bit per VF. When the bit is cleared, fetching of data for the VF's pool is disabled. When set, fetching of data for the VF's pool is enabled. Fetching of descriptors for the VF pool is maintained, up to the limit of the internal descriptor queues - regardless to VFTE settings.

The *VFRE* and *VFTE* registers apply in all device modes (not just IOV). The default values for both registers are therefore '1', enabling transmission and reception in non-IOV modes.

## 4.6.12 Alternate MAC Address Support

In some systems, the MAC address used by a port needs to be replaced with a temporary MAC address in a way that is transparent to the software layer. One possible usage is in blade systems, to allow a standby blade to use the MAC address of another blade that failed, so that the network image of the entire blade system does not change.

In order to allow this mode, a management console might change the MAC address in the EEPROM image. It is important in this case to be able to keep the original MAC address of the device as programmed at the factory.

In order to support this mode, the I350 provides the *Alternate Ethernet MAC Address* EEPROM structure to store the original MAC addresses. This structure is described in [Section 6.4.8](#). When the MAC address is changed the port Factory MAC address should be written to the *Alternate Ethernet MAC Address* structure before writing the new Ethernet MAC address to the ports *Ethernet Address* EEPROM words (refer to [Section 6.2.1](#)).

In some systems, it might be advantageous to restore the original MAC address at power on reset, to avoid conflicts where two network controllers would have the same MAC address. The I350 restores the LAN MAC addresses stored in the *Alternate Ethernet MAC Address* EEPROM structure to the regular *Ethernet MAC address* EEPROM words (refer to [Section 6.2.1](#)) if the following conditions are met:

1. The *restore MAC address* bit in the *Common Firmware Parameters* EEPROM word is set ([Section 6.3.7.2](#)).
2. The value in word 0x37 ([Section 6.4.8](#)) is not 0xFFFF.
3. The MAC address set in the regular *Ethernet MAC Address* EEPROM words is different than the address stored in the *Alternate Ethernet MAC Address* EEPROM structure.
4. The address stored in the *Alternate Ethernet MAC Address* structure is valid (not all zeros or all ones).

If the Factory MAC address was restored by the internal firmware, the *FWSM.Factory MAC address restored* bit is set. This bit is common to all ports. If the value at word 0x37 is valid, but the MAC addresses in the *Alternate MAC* structure are not valid (0xFFFFFFFF), the regular MAC address is backed up in the *Alternate MAC* structure.

The I350 supports replacement of the MAC address with via a BIOS CLP interface as described in TBR.

## 4.7 Access to Shared Resources

Part of the resources in the I350 are shared between several software entities - namely the drivers of the four ports and the internal firmware. In order to avoid contentions, a driver that needs to access one of these resources should use the flow described in [Section 4.7.1](#) in order to acquire ownership of this resource and use the flow described in [Section 4.7.2](#) in order to relinquish ownership of this resource.

The shared resources are:

1. EEPROM.
2. All PHYs or SerDes ports.

3. CSRs accessed by the internal firmware after the initialization process. Currently there are no such CSRs.
4. The flash.
5. Software to Software Mailbox.
6. Thermal Sensor registers.
7. Management Host Interface

**Note:** Any other software tool that accesses the register set directly should also follow the flow described below.

## 4.7.1 Acquiring Ownership Over a Shared Resource

The following flow should be used to acquire a shared resource:

1. Get ownership of the software/software semaphore *SWSM.SMBI* (offset 0x5B50 bit 0).
  - a. Read the *SWSM* register.
  - b. If *SWSM.SMBI* is read as zero, the semaphore was taken.
  - c. Otherwise, go back to step a.

This step assure that other software will not access the shared resources register (*SW\_FW\_SYNC*).
2. Get ownership of the software/firmware semaphore *SWSM.SWESMBI* (offset 0x5B50 bit 1):
  - a. Set the *SWSM.SWESMBI* bit.
  - b. Read *SWSM*.
  - c. If *SWSM.SWESMBI* was successfully set - the semaphore was acquired - otherwise, go back to step a.

This step assure that the internal firmware will not access the shared resources register (*SW\_FW\_SYNC*).
3. Software reads the Software-Firmware Synchronization Register (*SW\_FW\_SYNC*) and checks both bits in the pair of bits that control the resource it wishes to own.
  - a. If both bits are cleared (both firmware and other software does not own the resource), software sets the software bit in the pair of bits that control the resource it wishes to own.
  - b. If one of the bits is set (firmware or other software owns the resource), software tries again later.
4. Release ownership of the software/software semaphore and the software/firmware semaphore by clearing *SWSM.SMBI* and *SWSM.SWESMBI* bits.
5. At this stage, the shared resources is owned by the driver and it may access it. The *SWSM* and *SW\_FW\_SYNC* registers can now be used to take ownership of another shared resources.

**Notes:** Software ownership of *SWSM.SWESMBI* bit should not exceed 100 mS. If Software takes ownership for a longer duration, Firmware may implement a timeout mechanism and take ownership of the *SWSM.SWESMBI* bit.

Software ownership of bits in *SW\_FW\_SYNC* register should not exceed 1 Second. If Software takes ownership for a longer duration, Firmware may implement a timeout mechanism and take ownership of the relevant *SW\_FW\_SYNC* bits.

## 4.7.2 Releasing Ownership Over a Shared Resource

The following flow should be used to release a shared resource:

1. Get ownership of the software/software semaphore *SWSM.SMBI* (offset 0x5B50 bit 0).
  - a. Read the *SWSM* register.
  - b. If *SWSM.SMBI* is read as zero, the semaphore was taken.
  - c. Otherwise, go back to step a.

This step assures that other software will not access the shared resources register (*SW\_FW\_SYNC*).
2. Get ownership of the software/firmware semaphore *SWSM.SWESMBI* (offset 0x5B50 bit 1):
  - a. Set the *SWSM.SWESMBI* bit.
  - b. Read *SWSM*.
  - c. If *SWSM.SWESMBI* was successfully set - the semaphore was acquired - otherwise, go back to step a.

This step assure that the internal firmware will not access the shared resources register (*SW\_FW\_SYNC*).
3. Clear the bit in *SW\_FW\_SYNC* that controls the software ownership of the resource to indicate this resource is free.
4. Release ownership of the software/software semaphore and the software/firmware semaphore by clearing *SWSM.SMBI* and *SWSM.SWESMBI* bits.
5. At this stage, the shared resource are released by the driver and it may not access it. The *SWSM* and *SW\_FW\_SYNC* registers can now be used to take ownership of another shared resource.

### 4.7.3 Software to Software Mailbox

In order to allow different I350 drivers to coordinate activities, a simple mailbox mechanism is defined. This mechanism allows each driver to send a broadcast message to all the other drivers on the same device.

In order to send a message the following flow should be used:

1. The Driver that wants to send the message should acquire the mailbox semaphore (*SW\_FW\_SYNC.SW\_MB\_SM*) using the flow described in [Section 4.7.1](#).
2. The Driver should then write the message in the *SWMBWR* register.
3. All the drivers will then receive an interrupt (except for the driver that initiated the message) via the *SWMB* cause in the *ICR* registers.
4. All the drivers will read the *SWMB0*, *SWMB1*, *SWMB2* and *SWMB3* registers to understand which driver sent a message.

**Note:** The mapping of *SWMB0*, *SWMB1*, *SWMB2* and *SWMB3* registers is according to the physical ports. A function can detect which physical port it is mapped to, by reading the *STATUS.LAN ID* field.

5. If the message requires an acknowledgment from the other drivers, each driver may write an acknowledge message through their *SWMBWR* register.
6. The driver that sent the original message can then poll the *SWMB0*, *SWMB1*, *SWMB2* and *SWMB3* registers for acknowledge messages.
7. After the message was acknowledged, the driver that sent the original message should release the Software Mailbox semaphore (*SW\_FW\_SYNC.SW\_MB\_SM*) using the flow described in [Section 4.7.2](#).
  - Together with clearing the *SWSM.SMBI* and *SWSM.SWESMBI* bits when releasing the Software Mailbox semaphore, Software driver should also clear the *SWMBWR*, *SWMB0*, *SWMB1*, *SWMB2* and *SWMB3* registers by setting the *SWSM.SWMB\_CLR* bit to avoid confusion when future messages are sent.

## 5 Power Management

---

This section describes how power management is implemented in the I350. The I350 supports the Advanced Configuration and Power Interface (ACPI) specification as well as Advanced Power Management (APM).

Power management can be disabled via the *power management* bit in the *Initialization Control Word 1* EEPROM word (see [Section 6.2.2](#)), which is loaded during power-up reset. Even when disabled, the power management register set is still present. Power management support is required by the PCIe specification.

### 5.1 General Power State Information

#### 5.1.1 PCI Device Power States

The PCIe Specification defines function power states (D-states) that enable the platform to establish and control power states for the I350 ranging from fully on to fully off (drawing no power) and various in-between levels of power-saving states, annotated as D0-D3. Similarly, PCIe defines a series of link power states (L-states) that work specifically within the link layer between the I350 and its upstream PCIe port (typically in the host chipset).

The PCIe link state follows the power management state of the device. Since the I350 incorporates multiple PCI functions, the device power management state is defined as the power management state of the most awake function:

- If any function is in D0a state in ARI mode or either D0a or D0u in non-ARI mode, the PCIe link assumes the device is in D0 state. Else,
- If in ARI mode, at least one of the functions is in D3 state and the other functions are not in D0a state, or if in non-ARI mode all of the functions are in the D3 state, the PCIe link assumes the device is in D3 state. Else,
- The device is in Dr state (PE\_RST\_N is asserted to all functions).

For a given device D-state, only certain L-states are possible as follows.

- D0 (fully on): The I350 is completely active and responsive during this D-state. The link can be in either L0 or a low-latency idle state referred to as L0s. Minimizing L0s exit latency is paramount for enabling frequent entry into L0s while facilitating performance needs via a fast exit. A deeper link power state, L1 state, is supported as well.
- D1 and D2: These modes are not supported by the I350.
- D3 (off): Two sub-states of D3 are supported:
  - D3hot, where primary power is maintained.
  - D3cold, where primary power is removed.

Link states are mapped into device states as follows:

- D3hot maps to L1 to support clock removal on mobile platforms
- D3cold maps to L2 if auxiliary power is supported on the I350 with wake-capable logic, or to L3 if no power is delivered to the I350. A sideband PE\_WAKE\_N mechanism is supported to interface wake-enabled logic on mobile platforms during the L2 state.

## 5.1.2 PCIe Link Power States

Configuring the I350 into a D-state automatically causes the PCIe link to transition to the appropriate L-state.

- L2/L3 Ready: This link state prepares the PCIe link for the removal of power and clock. The I350 is in the D3hot state and is preparing to enter D3cold. The power-saving opportunities for this state include, but are not limited to, clock gating of all PCIe architecture logic, shutdown of the PLL, and shutdown of all transceiver circuitry.
- L2: This link state is intended to comprehend D3cold with auxiliary power support. Note that sideband PE\_WAKE\_N signaling exists to cause wake-capable devices to exit this state. The power-saving opportunities for this state include, but are not limited to, shutdown of all transceiver circuitry except detection circuitry to support exit, clock gating of all PCIe logic, and shutdown of the PLL as well as appropriate platform voltage and clock generators.
- L3 (link off): Power and clock are removed in this link state, and there is no auxiliary power available. To bring the I350 and its link back up, the platform must go through a boot sequence where power, clock, and reset are reapplied appropriately.

## 5.2 Power States

The I350 supports the D0 and D3 architectural power states as described earlier. Internally, the I350 supports the following power states:

- D0u (D0 un-initialized) - an architectural sub-state of D0
- D0a (D0 active) - an architectural sub-state of D0
- D3 - architecture state D3hot
- Dr - internal state that contains the architecture D3cold state. Dr state is entered when PE\_RST\_N is asserted or a PCIe in-band reset is received

Figure 5-1 shows the power states and transitions between them.

**Figure 5-1 Power Management State Diagram**

## 5.2.1 D0 Uninitialized State (D0u)

The D0u state is an architectural low-power state.

When entering D0u, the I350:

- Asserts a reset to the PHY while the EEPROM is being read.
- Disables wake up. However APM wake up is enabled (See additional information in [Section 5.6.1](#)), if all of the following register bits are set:
  - The *WUC.APME* bit is set to 1b.
  - The *WUC.APM PME* bit or the *PMCSR.PME\_en* bits are set to 1b.
  - The *WUC.EN\_APM\_D0* bit is set to 1b.

### 5.2.1.1 Entry into D0u State

D0u is reached from either the Dr state (on de-assertion of *PE\_RST\_N*) or the D3hot state (by configuration software writing a value of 00b to the *Power State* field of the PCI PM registers).

De-asserting *PE\_RST\_N* means that the entire state of the I350 is cleared, other than sticky bits. State is loaded from the EEPROM, followed by establishment of the PCIe link. Once this is done, configuration software can access the I350.

On a transition from D3hot state to D0u state, the I350 PCI configuration space is not reset (since the *No\_Soft\_Reset* bit in the *PMCSR* register is set to 1b). However following move to D0a state, the I350 requires that the software driver perform a full re-initialization of the function.

## 5.2.2 D0active State

Once memory space is enabled, the I350 enters the D0 active state. It can transmit and receive packets if properly configured by the software device driver. The PHY is enabled or re-enabled by the software device driver to operate/auto-negotiate to full line speed/power if not already operating at full capability.

### Notes:

1. In the I350 if the *WUC.EN\_APM\_D0* is cleared to 0 an APM wake event due to reception of a Magic packet is not generated when the function is not in D3 (or Dr) state. Any APM wake up previously active remains active when moving from D3 to D0.
2. If APM wake is required in D3 software driver should not disable APM wake-up via the *WUC.APME* bit on D0 entry. Otherwise APM wake following a system crash and entry into S3, S4 or S5 system power management state will not be enabled.
3. Following entry into D0 software device driver can activate other wake-up filters by writing to the Wake Up Filter Control (*WUFC*) register.

### 5.2.2.1 Entry to D0a State

D0a is entered from the D0u state by writing a 1b to the *Memory Access Enable* or the *I/O Access Enable* bit of the PCI Command register (See [Section 9.4.3](#)). The DMA, MAC, and PHY of the appropriate LAN function are also enabled.

## 5.2.3 D3 State (PCI-PM D3hot)

The I350 transitions to D3 when the system writes a 11b to the Power State field of the *Power Management Control/Status Register (PMCSR)*. Any wake-up filter settings that were enabled before entering this state are maintained. If the *PMCSR.No\_Soft\_reset* bit is cleared upon completion or during the transition to D3 state, the I350 clears the *Memory Access Enable* and *I/O Access Enable* bits of the PCI Command register, which disables memory access decode. If the *PMCSR.No\_Soft\_reset* bit is set the I350 doesn't clear any bit in the PCIe configuration space. While in D3, the I350 does not generate master cycles.

Configuration and message requests are the only TLPs accepted by a function in the D3hot state. All other received requests must be handled as unsupported requests, and all received completions are handled as unexpected completions. If an error caused by a received TLP (such as an unsupported request) is detected while in D3hot, and reporting is enabled, the link must be returned to L0 if it is not already in L0 and an error message must be sent. See section 5.3.1.4.1 in The PCIe Base Specification.

### 5.2.3.1 Entry to D3 State

Transition to D3 state is through a configuration write to the *Power State* field of the *PMCSR* PCIe configuration register.

Prior to transition from D0 to the D3 state, the software device driver disables scheduling of further tasks to the I350; it masks all interrupts and does not write to the Transmit Descriptor Tail (*TDT*) register or to the Receive Descriptor Tail (*RDT*) register and operates the master disable algorithm as defined in [Section 5.2.3.3](#).

If wake up capability is needed, system should enable wake capability by setting to 1b the *PME\_En* bit in the *PMCSR* PCIe configuration register. After Wake capability has been enabled Software device driver should set up the appropriate wake up registers (*WUC*, *WUFC* and associated filters) prior to the D3 transition.

**Note:** Software driver can override the *PMCSR.PME\_En* bit setting via the *WUC.APMPME* bit.

If Protocol offload (Proxying) capability is required and the *MANC.MPROXYE* bit is set to 1b Software device driver should:

1. Send to the management Firmware the relevant protocol offload information (Type of protocol offloads required, MAC and IPv4/6 addresses information for protocol offload) via the shared RAM Firmware/Software Host interface as defined in [Section 8.22.1](#), [Section 10.8](#) and [Section 10.8.2.4.2](#).
2. Program the *PROXYFC* register and associated filters according to the protocol offload required.
3. Program the *WUC.PPROXYE* bit to 1b.

**Note:** If operation during D3<sub>cold</sub> is required, even when Wake capability is not required (e.g. for manageability operation), system should also set the *Auxiliary (AUX) Power PM Enable* bit in the *PCIe Device Control register*.

As a response to being programmed into D3 state, the I350 transitions its PCIe link into the L1 link state. As part of the transition into L1 state, the I350 suspends scheduling of new TLPs and waits for the completion of all previous TLPs it has sent. If the *PMCSR.No\_Soft\_reset* bit is cleared the I350 clears the *Memory Access Enable* and *I/O Access Enable* bits of the PCI Command register, which disables memory access decode. Any receive packets that have not been transferred into system memory are kept in the I350 (and discarded later on D3 exit). Any transmit packets that have not been sent can still be transmitted (assuming the Ethernet link is up).

In order to reduce power consumption, if the link is still needed for manageability, wake-up or proxying functionality, the PHY can auto-negotiate to a lower link speed on D3 entry (See [Section 3.7.8.5.4](#)). In addition in preparation for a possible transition to D3cold state, the device driver might disable some of the LAN ports to further reduce power consumption.

### 5.2.3.2 Exit from D3 State

A D3 state is followed by either a D0u state (in preparation for a D0a state) or by a transition to Dr state (PCI-PM D3cold state). To transition back to D0u, the system writes a 00b to the *Power State* field of the *Power Management Control/Status Register (PMCSR)*. Transition to Dr state is through *PE\_RST\_N* assertion.

The *No\_Soft\_Reset* bit in the *PCIe Power Management Control / Status (PMCSR)* register in the I350 is set to 1b, to indicate that the I350 does not perform an internal reset on transition from D3hot to D0 so that transition will not disrupt the proper operation of other active Functions. In this case, software is not required to re-initialize the function's configuration space after a transition from D3hot to D0 (the Function will be in the D0<sub>initialized</sub> state), however the Software driver needs to re-initialize internal registers since transition from D3hot to D0 causes an internal port reset (similar to asserting the *CTRL.RST* bit).

The I350 can be configured via EEPROM to clear the *No\_Soft\_Reset* bit in the *PMCSR* register (See [Section 6.2.17](#)). In this case an internal reset is generated when transition from D3hot to D0 occurs and functional context is not maintained also in PCIe configuration bits (except for bits defined as sticky). As a result, in this case software is required to fully re-initialize the Function after a transition to D0 as the Function will be in the D0<sub>uninitialized</sub> state.

**Note:** The Function will be reset if the Link state transitions to the L2/L3 Ready state, on transition from D3cold to D0, if FLR is asserted or if transition D3hot to D0 is caused by assertion of PCIe reset (PE\_RST pin) regardless of the value of the *No\_Soft\_Reset* bit.

### 5.2.3.3 Master Disable Via CTRL Register

System software can disable master accesses on the PCIe link by either clearing the *PCI Bus Master* bit or by bringing the function into a D3 state. From that time on, the I350 must not issue master accesses for this function. Due to the full-duplex nature of PCIe, and the pipelined design in the I350, it might happen that multiple requests from several functions are pending when the master disable request arrives. The protocol described in this section insures that a function does not issue master requests to the PCIe link after its *Master Enable* bit is cleared (or after entry to D3 state).

Two configuration bits are provided for the handshake between the I350 function and its software device driver:

- *GIO Master Disable* bit in the Device Control (*CTRL*) register - When the *GIO Master Disable* bit is set, the I350 blocks new master requests by this function. The I350 then proceeds to issue any pending requests by this function. This bit is cleared on master reset (LAN\_PWR\_GOOD, PCIe reset and software reset) to enable master accesses.
- *GIO Master Enable Status* bit in the Device Status (*STATUS*) register - Cleared by the I350 when the *GIO Master Disable* bit is set and no master requests are pending by the relevant function and is set otherwise. Indicates that no master requests are issued by this function as long as the *GIO Master Disable* bit is set. The following activities must end before the I350 clears the *GIO Master Enable Status* bit:
  - Master requests by the transmit and receive engines (for both data and MSI/MSIx interrupts).
  - All pending completions to the I350 are received.

In the event of a PCIe Master disable (*Configuration Command register.BME* set to 0) on a certain function or LAN port or if the function is moved into D3 state during a DMA access, the I350 generates an internal reset to the function and stops all port DMA accesses and interrupts related to the function. Following move to normal operating mode software driver should re-initialize the receive and transmit queues of the relevant port.

**Notes:** The software device driver sets the *GIO Master Disable* bit when notified of a pending master disable (or D3 entry). The I350 then blocks new requests and proceeds to issue any pending requests by this function. The software device driver then polls the *GIO Master Enable Status* bit. Once the bit is cleared, it is guaranteed that no requests are pending from this function. The software device driver might time out if the *GIO Master Enable Status* bit is not cleared within a given time.

The *GIO Master Disable* bit must be cleared to enable a master request to the PCIe link. This can be done either through reset or by the software device driver.

### 5.2.4 Dr State (D3cold)

Transition to Dr state is initiated on several occasions:

- On system power up - Dr state begins with the assertion of the internal power detection circuit and ends with de-assertion of *PE\_RST\_N*.
- On transition from a D0a state - During operation the system might assert *PE\_RST\_N* at any time. In an ACPI system, a system transition to the G2/S5 state causes a transition from D0a to Dr state.
- On transition from a D3 state - The system transitions the I350 into the Dr state by asserting PCIe *PE\_RST\_N*.

Any wake-up filter settings or proxying filter settings that were enabled before entering this reset state are maintained.

The system might maintain *PE\_RST\_N* asserted for an arbitrary time. The de-assertion (rising edge) of *PE\_RST\_N* causes a transition to D0u state.

While in Dr state, the I350 might enter one of several modes with different levels of functionality and power consumption. The lower-power modes are achieved when the I350 is not required to maintain any functionality (see [Section 5.2.4.1](#)).

**Note:** If the I350 is configured to provide a 50 MHz NC-SI clock (via the *NC-SI Output Clock* EEPROM bit), then the NC-SI clock must be provided in Dr state as well.

### 5.2.4.1 Dr Disable Mode

The I350 enters a Dr disable mode on transition to D3cold state when it does not need to maintain any functionality. The conditions to enter either state are:

- The I350 (all PCI functions) is in Dr state
- APM WoL (Wake-on-LAN) is inactive for all LAN functions
- Proxying is not required for all LAN functions (*WUC.PPROXYE* is cleared to 0b).
- Pass-through manageability is disabled
- ACPI PME is disabled for all PCI functions
- The I350 *Power Down Enable* EEPROM bit (word 0x1E, bit 15) is set (default hardware value is disabled).
- The *PHY Power Down Enable* EEPROM bit is set (word 0xF, bit 6).

Entering Dr disable mode is usually done by asserting PCIe *PE\_RST\_N*. It might also be possible to enter Dr disable mode by reading the EEPROM while already in Dr state. The usage model for this later case is on system power up, assuming that manageability, wake up and proxying are not required. Once the I350 enters Dr state on power-up, the EEPROM is read. If the EEPROM contents determine that the conditions to enter Dr disable mode are met, the I350 then enters this mode (assuming that PCIe *PE\_RST\_N* is still asserted).

The I350 exits Dr disable mode when Dr state is exited (See [Figure 5-1](#) for conditions to exit Dr state).

### 5.2.4.2 Entry to Dr State

Dr entry on platform power-up begins with the assertion of the internal power detection circuit. The EEPROM is read and determines the I350 configuration. If the *APM Enable* bit in the EEPROM's *Initialization Control Word 3* is set, then APM wake up is enabled. PHY and MAC states are redetermined by the state of manageability and APM wake. To reduce power consumption, if manageability or APM wake is enabled, the PHY auto-negotiates to a lower link speed on Dr entry (See [Section 3.7.8.5.4](#)). The PCIe link is not enabled in Dr state following system power up (since *PE\_RST\_N* is asserted).

Entering Dr state from D0a state is done by asserting *PE\_RST\_N*. An ACPI transition to the G2/S5 state is reflected in the I350 transition from D0a to Dr state. The transition can be orderly (such as user selecting the shut down option), in which case the software device driver might have a chance to intervene. Or, it might be an emergency transition (such as power button override), in which case, the software device driver is not notified.

To reduce power consumption, if any of manageability, APM wake or PCI-PM PME<sup>1</sup> is enabled, the PHY auto-negotiates to a lower link speed on D0a to Dr transition (see [Section 3.7.8.5.4](#)).

Transition from D3 (hot) state to Dr state is done by asserting *PE\_RST\_N*. Prior to that, the system initiates a transition of the PCIe link from L1 state to either the L2 or L3 state (assuming all functions were already in D3 state). The link enters L2 state if PCI-PM PME is enabled.

### 5.2.4.3 Auxiliary Power Usage

The EEPROM *D3COLD\_WAKEUP\_ADVEN* bit and the *AUX\_PWR* strapping pin determine when D3cold PME is supported:

- *D3COLD\_WAKEUP\_ADVEN* denotes that PME wake should be supported
- *AUX\_PWR* strapping pin indicates that auxiliary power is provided

D3cold PME is supported as follows:

- If the *D3COLD\_WAKEUP\_ADVEN* is set to '1' and the *AUX\_PWR* strapping is set to '1', then D3cold PME is supported
- Else D3cold PME is not supported

The amount of power required for the function (including the entire NIC) is advertised in the *Power Management Data* register, which is loaded from the EEPROM.

If D3cold is supported, the *PME\_En* and *PME\_Status* bits of the *Power Management Control/Status* Register (PMCSR), as well as their shadow bits in the Wake Up Control (WUC) register are reset only by the power up reset (detection of power rising).

### 5.2.5 Link Disconnect

In any of D0u, D0a, D3, or Dr power states, the I350 enters a link-disconnect state if it detects a link-disconnect condition on the Ethernet link. Note that the link-disconnect state in the internal PHY is invisible to software (other than the *PHPM.Link Energy Detect* bit state). In particular, while in D0 state, software might be able to access any of the I350 registers as in a link-connect state.

### 5.2.6 Device Power-Down State

The I350 enters a global power-down state if all of the following conditions are met:

- The I350 *Power Down Enable* EEPROM bit (word 0x1E bit 15) was set (default hardware value is disabled).
- The I350 is in Dr state.

---

1. ACPI 2.0 specifies that "OSPM will not disable wake events before setting the SLP\_EN bit when entering the S5 sleeping state. This provides support for remote management initiatives by enabling Remote Power On (RPO) capability. This is a change from ACPI 1.0 behavior."

- The link connections of all ports (PHY or SerDes) are in power down mode.

The I350 also enters a power-down state when the DEV\_OFF\_N pin is asserted and the relevant EEPROM bits were configured as previously described (see [Section 4.5](#) for more details on DEV\_OFF\_N functionality).

## 5.3 Power Limits by Certain Form Factors

Table 5-1 lists power limitation introduced by different form factors.

**Table 5-1 Power Limits by Form-Factor**

|                          | Form Factor    |                              |
|--------------------------|----------------|------------------------------|
|                          | LOM            | PCIe add-in card (10 W slot) |
| Main                     | N/A            | 3 A @ 3.3 V                  |
| Auxiliary (aux enabled)  | 375 mA @ 3.3 V | 375 mA @ 3.3 V               |
| Auxiliary (aux disabled) | 20 mA @ 3.3 V  | 20 mA @ 3.3 V                |

**Note:** This auxiliary current limit only applies when the primary 3.3 V voltage source is not available (the card is in a low power D3 state).

The I350 exceeds the allocated auxiliary power in some configurations (such as all ports running at 1000 Mb/s speed). The I350 must therefore be configured to meet the previously mentioned requirements. To do so, the I350 implements three EEPROM bits to disable operation in certain cases:

1. The *PHPM.Disable\_1000* PHY register bit disables 1000 Mb/s operation under all conditions.
2. The *PHPM.Disable\_1000 in non-D0a* PHY CSR bit disables 1000 Mb/s operation in non-D0a states<sup>1</sup>. If *PHPM.Disable\_1000 in non-D0a* is set, and the I350 is at 1000 Mb/s speed on entry to a non-D0a state, then the I350 removes advertisement for 1000 Mb/s and auto-negotiates.
3. The *PHPM.Disable\_100 in non-D0a* PHY CSR bit disables 1000 Mb/s and 100 Mb/s operation in non-D0a states. If *PHPM.Disable\_100 in non-D0a* is set, and the I350 is at 1000 Mb/s or 100 Mb/s speeds on entry to a non-D0a state, then the I350 removes advertisement for 1000 Mb/s and 100 Mb/s and auto-negotiates.

Note that the I350 restarts link auto-negotiation each time it transitions from a state where 1000 Mb/s or 100 Mb/s speed is enabled to a state where 1000 Mb/s or 100 Mb/s speed is disabled, or vice versa. For example, if *PHPM.Disable\_1000 in non-D0a* is set but *PHPM.Disable\_1000* is cleared, the I350 restarts link auto-negotiation on transition from D0 state to D3 or Dr states.

## 5.4 Interconnects Power Management

This section describes the power reduction techniques employed by the I350 main interconnects.

---

1. The restriction is defined for all non-D0a states to have compatible behavior with previous products.

## 5.4.1 PCIe Link Power Management

The PCIe link state follows the power management state of the I350. Since the I350 incorporates multiple PCI functions, its power management state is defined as the power management state of the most awake function (see [Figure 5-2](#)):

- If any function is in D0 state (either D0a or D0u), the PCIe link assumes the I350 is in D0 state. Else,
- If the functions are in D3 state, the PCIe link assumes the I350 is in D3 state. Else,
- The I350 is in Dr state (PE\_RST\_N is asserted to all functions).

The I350 supports all PCIe power management link states:

- L0 state is used in D0u and D0a states.
- The L0s state is used in D0a and D0u states each time link conditions apply.
- The L1 state is also used in D0a and D0u states when idle conditions apply for a longer period of time. The L1 state is also used in the D3 state.
- The L2 state is used in the Dr state following a transition from a D3 state if *PCI-PM PME* is enabled.
- The L3 state is used in the Dr state following power up, on transition from D0a, and if *PME* is not enabled in other Dr transitions.

The I350 support for active state link power management is reported via the *PCIe Active State Link PM Support* register and is loaded from the EEPROM.

**Figure 5-2 Link Power Management State Diagram**

While in L0 state, the I350 transitions the transmit lane(s) into L0s state once the idle conditions are met for a period of time as follows:

L0s configuration fields are:

- L0s enable - The default value of the *Active State Link PM Control* field in the PCIe *Link Control* Register is set to 00b (both L0s and L1 disabled). System software may later write a different value into the Link Control Register. The default value is loaded on any reset of the PCI configuration registers.
- L0s exit latency (as published in the L0s Exit Latency field of the Link Capabilities Register) is loaded from EEPROM. Separate values are loaded when the I350 shares the same reference PCIe clock with its partner across the link, and when the I350 uses a different reference clock than its partner across the link. The I350 reports whether it uses the slot clock configuration through the PCIe Slot Clock Configuration bit loaded from the *Slot\_Clock\_Cfg* bit in the *PCIe Init Configuration 3* EEPROM Word.
- L0s Acceptable Latency (as published in the Endpoint L0s Acceptable Latency field of the Device Capabilities Register) is loaded from EEPROM.

The I350 transitions the PCIe link into low power state as defined in the *DMACR.DMAC\_Lx* field once it detects no PCIe activity for a duration defined in the *DMCTLX.TTLX* field.

**Note:** To comply with the PCIe specification if the link idle time exceeds the *Latency\_To\_Enter\_L0s* value defined in the EEPROM then the I350 will enter L0s even if the PCIe idle time defined in the *DMCTLX.TTLX* field has not expired. Once the PCIe idle time defined in the *DMCTLX.TTLX* has expired the I350 enters L1 according to the programming of the *DMACR.DMAC\_Lx* field.

The following EEPROM fields control L1 behavior:

- *Act\_Stat\_PM\_Sup* - Indicates support for ASPM L1 in the PCIe configuration space (loaded into the Active State Link PM Support field)
- *L1\_Act\_Ext\_Latency* - Defines L1 active exit latency
- *L1\_Act\_Acc\_Latency* - Defines L1 active acceptable exit latency
- *Latency\_To\_Enter\_L1* - Defines the period (in the L0s state) before the transition into L1 state

## 5.4.2 NC-SI Clock Control

The I350 can be configured to provide a 50 MHz output clock to its NC-SI interface and other platform devices. When enabled through the *NC-SI Output Clock Disable* EEPROM bit (See [Section 6.2.22](#)), the NC-SI clock is provided in all power states without exception.

## 5.4.3 Internal PHY Power-Management

The PHY power management features are described in [Section 3.7.8.5](#).

# 5.5 Timing of Power-State Transitions

The following sections give detailed timing for the state transitions. In the diagrams the dotted connecting lines represent I350 requirements, while the solid connecting lines represent the I350 guarantees.

The timing diagrams are not to scale. The clocks edges are shown to indicate running clocks only and are not to be used to indicate the actual number of cycles for any operation.

## 5.5.1 Power Up (Off to Dup to D0u to D0a)

**Figure 5-3 Power Up (Off to Dup to D0u to D0a)**

**Table 5-2 Power Up (Off to Dup to D0u to D0a)**

| Note | Description                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------|
| 1    | Xosc is stable $t_{xog}$ after power is stable.                                                                             |
| 2    | LAN_PWR_GOOD is asserted after all power supplies are good and $t_{ppg}$ after Xosc is stable.                              |
| 3    | An EEPROM read starts on the rising edge of LAN_PWR_GOOD.                                                                   |
| 4    | After reading the EEPROM, PHY reset is de-asserted.                                                                         |
| 5    | APM wake-up mode can be enabled based on what is read from the EEPROM.                                                      |
| 6    | The PCIe reference clock is valid $t_{PE\_RST\_CLK}$ before de-asserting PE_RST_N (according to PCIe specification).        |
| 7    | PE_RST_N is de-asserted $t_{pVPG}$ after power is stable (according to PCIe specification).                                 |
| 8    | The internal PCIe clock is valid and stable $t_{ppg-clkint}$ from PE_RST_N de-assertion.                                    |
| 9    | The PCIe internal PWRGD signal is asserted $t_{clkpr}$ after the external PE_RST_N signal.                                  |
| 10   | Asserting internal PCIe PWRGD causes the EEPROM to be re-read, asserts PHY reset, and disables wake up.                     |
| 11   | After reading the EEPROM, PHY reset is de-asserted.                                                                         |
| 12   | Link training starts after $t_{pgtrn}$ from PE_RST_N de-assertion.                                                          |
| 13   | A first PCIe configuration access might arrive after $t_{pgcfg}$ from PE_RST_N de-assertion.                                |
| 14   | A first PCI configuration response can be sent after $t_{pgres}$ from PE_RST_N de-assertion.                                |
| 15   | Writing a 1b to the <i>Memory Access Enable</i> bit in the PCI Command Register transitions the I350 from D0u to D0. state. |

## 5.5.2 Transition from D0a to D3 and Back Without PE\_RST\_N

**Figure 5-4 Transition from D0a to D3 and Back Without PE\_RST\_N**

**Table 5-3 Transition from D0a to D3 and Back Without PE\_RST\_N**

| Note | Description                                                                                                                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Writing 11b to the <i>Power State</i> field of the Power Management Control/Status Register (PMCSR) transitions the I350 to D3.                                                                                     |
| 2    | The system can keep the I350 in D3 state for an arbitrary amount of time.                                                                                                                                           |
| 3    | To exit D3 state, the system writes 00b to the <i>Power State</i> field of the PMCSR.                                                                                                                               |
| 4    | APM wake-up or SMBus mode might be enabled based on what is read in the EEPROM.                                                                                                                                     |
| 5    | After reading the EEPROM, reset to the PHY is de-asserted. The PHY operates at reduced-speed if APM wake up or SMBus is enabled, else powered-down.                                                                 |
| 6    | The system can delay an arbitrary time before enabling memory access.                                                                                                                                               |
| 7    | Writing a 1b to the <i>Memory Access Enable</i> bit or to the <i>I/O Access Enable</i> bit in the PCI Command Register transitions the I350 from D0u to D0 state and returns the PHY to full-power/speed operation. |

### 5.5.3 Transition From D0a to D3 and Back With PE\_RST\_N

**Figure 5-5 Transition From D0a to D3 and Back With PE\_RST\_N**

**Table 5-4 Transition From D0a to D3 and Back With PE\_RST\_N**

| Note | Description                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Writing 11b to the <i>Power State</i> field of the PMCSR transitions the I350 to D3. PCIe link transitions to L1 state.                                                     |
| 2    | The system can delay an arbitrary amount of time between setting D3 mode and moving the link to a L2 or L3 state.                                                           |
| 3    | Following link transition, PE_RST_N is asserted.                                                                                                                            |
| 4    | The system must assert PE_RST_N before stopping the PCIe reference clock. It must also wait $t_{i2clk}$ after link transition to L2/L3 before stopping the reference clock. |
| 5    | On assertion of PE_RST_N, the I350 transitions to Dr state.                                                                                                                 |
| 6    | The system starts the PCIe reference clock $t_{PE\_RST\_CLK}$ before de-assertion PE_RST_N.                                                                                 |
| 7    | The internal PCIe clock is valid and stable $t_{ppg-clkint}$ from PE_RST_N de-assertion.                                                                                    |
| 8    | The PCIe internal PWRGD signal is asserted $t_{clkpr}$ after the external PE_RST_N signal.                                                                                  |
| 9    | Asserting internal PCIe PWRGD causes the EEPROM to be re-read, asserts PHY reset, and disables wake up.                                                                     |
| 10   | APM wake-up mode might be enabled based on what is read from the EEPROM.                                                                                                    |
| 11   | After reading the EEPROM, PHY reset is de-asserted.                                                                                                                         |
| 12   | Link training starts after $t_{pgtrn}$ from PE_RST_N de-assertion.                                                                                                          |
| 13   | A first PCIe configuration access might arrive after $t_{pgcfg}$ from PE_RST_N de-assertion.                                                                                |
| 14   | A first PCI configuration response can be sent after $t_{pgres}$ from PE_RST_N de-assertion.                                                                                |
| 15   | Writing a 1b to the <i>Memory Access Enable</i> bit in the PCI Command Register transitions the I350 from D0u to D0 state.                                                  |

## 5.5.4 Transition From D0a to Dr and Back Without Transition to D3

**Figure 5-6 Transition From D0a to Dr and Back Without Transition to D3**

**Table 5-5 Transition From D0a to Dr and Back Without Transition to D3**

| Note | Description                                                                                                                                                                     |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | The system must assert $PE\_RST\_N$ before stopping the PCIe reference clock. It must also wait $t_{l2clk}$ after link transition to L2/L3 before stopping the reference clock. |
| 2    | On assertion of $PE\_RST\_N$ , the I350 transitions to Dr state and the PCIe link transitions to electrical idle.                                                               |
| 3    | The system starts the PCIe reference clock $t_{PE\_RST\_CLK}$ before de-assertion $PE\_RST\_N$ .                                                                                |
| 4    | The internal PCIe clock is valid and stable $t_{ppg-clkint}$ from $PE\_RST\_N$ de-assertion.                                                                                    |
| 5    | The PCIe internal PWRGD signal is asserted $t_{clkpr}$ after the external $PE\_RST\_N$ signal.                                                                                  |
| 6    | Asserting internal PCIe PWRGD causes the EEPROM to be re-read, asserts PHY reset, and disables wake up.                                                                         |
| 7    | APM wake-up mode might be enabled based on what is read from the EEPROM.                                                                                                        |
| 8    | After reading the EEPROM, PHY reset is de-asserted.                                                                                                                             |
| 9    | Link training starts after $t_{pgtrn}$ from $PE\_RST\_N$ de-assertion.                                                                                                          |
| 10   | A first PCIe configuration access might arrive after $t_{pgcfg}$ from $PE\_RST\_N$ de-assertion.                                                                                |
| 11   | A first PCI configuration response can be sent after $t_{pgres}$ from $PE\_RST\_N$ de-assertion.                                                                                |
| 12   | Writing a 1b to the <i>Memory Access Enable</i> bit in the PCI Command Register transitions the I350 from D0u to D0 state.                                                      |

## 5.6 Wake Up

The I350 supports two modes of wake-up management:

1. Advanced Power Management (APM) wake up
2. ACPI/PCIe defined wake up

The usual model is to activate one mode at a time but not both modes together. If both modes are activated, the I350 might wake up the system on unexpected events. For example, if APM is enabled together with the ACPI/PCIe Magic packet in the *WUFC* register, a magic packet might wake up the system even if APM is disabled (*WUC.APME* = 0b). Alternatively, if APM is enabled together with some of the ACPI/PCIe filters (enabled in the *WUFC* register), packets matching these filters might wake up the system even if PCIe PME is disabled.

### 5.6.1 Advanced Power Management Wake Up

Advanced Power Management Wake Up or APM Wakeup (also known as Wake on LAN) is a feature that existed in earlier 10/100 Mb/s NICs. This functionality was designed to receive a broadcast or unicast packet with an explicit data pattern, and then assert a subsequent signal to wake up the system. This was accomplished by using a special signal that ran across a cable to a defined connector on the motherboard. The NIC would assert the signal for approximately 50 ms to signal a wake up. The I350 now uses (if configured) an in-band PM\_PME message for this functionality.

On power up, the I350 reads the *APM Enable* bits from the EEPROM *Initialization Control Word 3* into the *APM Enable* (*APME*) bits of the *Wakeup Control* (*WUC*) register. These bits control enabling of APM wake up.

When APM wake up is enabled, the I350 checks all incoming packets for Magic Packets. See [Section 5.6.3.1.4](#) for a definition of Magic Packets.

Once the I350 receives a matching Magic packet, and if the *WUC.APMPME* bit or the *PMCSR.PME\_En* bits are set to 1b and the *WUC.APME* bit is set to 1b it:

- Sets the *PME\_Status* bit in the *PMCSR* register and issues a PM\_PME message (in some cases, this might require asserting the *PE\_WAKE\_N* signal first to resume power and clock to the PCIe interface).
- Stores the first 128 bytes of the packet in the Wake Up Packet Memory (*WUPM*) register.
- Sets the *Magic Packet Received* bit in the Wake Up Status (*WUS*) register.
- Sets the packet length in the Wake Up Packet Length (*WUPL*) register.

The I350 maintains the first Magic Packet received in the *Wake Up Packet Memory* (*WUPM*) register until the software device driver writes a 1b to the *WUS.MAG* bit.

If the *WUC.EN\_APM\_D0* bit is set to 1b APM wake up is supported in all power states and only disabled if a subsequent EEPROM read results in the *WUC.APME* bit being cleared or software explicitly writes a 0b to the *WUC.APME* bit. If the *WUC.EN\_APM\_D0* bit is cleared APM wake-up is supported only in the D3 or Dr power states.

#### Notes:

1. When the *WUC.APMPME* bit is set a wake event is issued (*PE\_WAKE\_N* pin is asserted and a PM\_PME PCIe message is issued) even if the *PMCSR.PME\_En* bit in configuration space is cleared.

To enable disabling of system Wake-up when *PMCSR.PME\_En* is cleared, Software driver should clear the *WUC.APMPME* bit after power-up or PCIe reset.

2. So long as APM is enabled and the I350 is programmed to issue a wake event on the PCIe, each time a Magic packet is received. A wake event is generated on the PCIe interface even if the *WUS.MAG* bit is set as a result of reception of a previous Magic packet. Consecutive magic packets will generate consecutive Wake events.

## 5.6.2 ACPI Power Management Wake Up

The I350 supports PCIe power management based wake-up. It can generate system wake-up events from a number of sources:

- Reception of a Magic Packet.
- Reception of a network wakeup packet.
- Detection of change in network link state (cable connected or disconnected).
- Detection of a thermal event due to crossing of a thermal trip point.
- Wake-up by Manageability on reception of an unsupported packets for Proxying.

Activating PCIe power management wake up requires the following:

- System software writes at configuration time a 1b to the PCI *PMCSR.PME\_En* bit.
- Software device driver clears all pending wake-up status bits in the Wake Up Status (*WUS*) register.
- The software device driver programs the Wake Up Filter Control (*WUFC*) register to indicate the packets that should initiate system wake up and programs the necessary data to the IPv4/v6 Address Table (*IP4AT*, *IP6AT*) and the Flexible Host Filter Table (*FHFT*). It can also set the *WUFC.LNKC* bit and/or the *WUFC.TS* bit to cause wake up on link status change or thermal event.
- Once the I350 wakes the system, the driver needs to clear the *WUS* and *WUFC* registers until the next time the system moves to a low power state with wake up enabled.

Normally, after enabling wake up, system software moves the device to D3 low power state by writing a 11b to the PCI *PMCSR.Power State* field.

Once wake up is enabled, the I350 monitors incoming packets, first filtering them according to its standard address filtering method, then filtering them with all of the enabled wakeup filters. If a packet passes both the standard address filtering and at least one of the enabled wakeup filters, the I350:

- Sets the *PME\_Status* bit in the *PMCSR*.
- Asserts *PE\_WAKE\_N* (if the *PME\_En* bit in the *PMCSR* configuration register is set).
- Stores the first 128 bytes of the packet in the *Wakeup Packet Memory (WUPM)* register.
- Sets one or more bits in the *Wake Up Status (WUS)* register. Note that the I350 sets more than one bit if a packet matches more than one filter.
- Sets the packet length in the *Wake Up Packet Length (WUPL)* register.

**Note:** If enabled, a link state change wake-up or a thermal sensor event wake-up also causes similar results. Sets the *PMCSR.PME\_Status* bit, asserts the *PE\_WAKE\_N* signal and sets the relevant bit in the *WUS* register.

The *PE\_WAKE\_N* remains asserted until the operating system either writes a 1b to the *PMCSR.PME\_Status* bit or writes a 0b to the *PMCSR.PME\_En* bit.

After receiving a wake-up packet, the I350 ignores any subsequent wake-up packets until the software device driver clears all of the received bits in the Wake Up Status (WUS) register. It also ignores link change events until the software device driver clears the *Link Status Changed (LNKC)* bit in the *Wake Up Status (WUS)* register.

**Note:** A wake on link change is not supported when configured to SerDes or 1000BASE-KX mode.

## 5.6.3 Wake-Up and Proxying Filters

The I350 supports issuing wake-up to Host when device is in D3 or protocol offload (Proxying) of packets using two types of filters:

- Pre-defined filters
- Flexible filters

Each of these filters are enabled if the corresponding bit in the *Wake Up Filter Control (WUFC)* register or *Proxying Filter Control (PROXYFC)* register is set to 1b.

**Note:** When VLAN filtering is enabled, packets that passed any of the receive wake-up filters should only cause a wake-up event if they also passed the VLAN filtering.

### 5.6.3.1 Pre-Defined Filters

The following packets are supported by the I350's pre-defined filters:

- Directed packet (including exact, multicast indexed, and broadcast)
- Magic Packet
- ARP/IPv4 request packet
- Directed IPv4 packet
- Directed IPv6 packet
- ICMPv6 packet like:
  - IPv6 Neighbor Solicitation (NS) packet
  - IPv6 Multicast Listener Discovery (MLD) packet

Each of these filters are enabled if the corresponding bit in the *Wakeup Filter Control (WUFC)* register or *Proxying Filter Control (PROXYFC)* register is set to 1b.

Following sections include a description of each filter and a table describing which bytes at which offsets need to be compared, to determine if the packet passes the filter.

**Note:** Both VLAN fields and LLC/SNAP fields can increase the given offsets if they are present.

#### 5.6.3.1.1 Directed Exact Packet

The I350 generates a wake-up event after receiving any packet whose destination address matches one of the 32 valid programmed receive destination MAC addresses (defined in the *RAL* and *RAH* registers), if the *Directed Exact Wake Up Enable* bit is set in the *Wake Up Filter Control (WUFC.EX)* register.

The I350 forwards a packet to Management for Proxying after receiving any packet whose MAC destination address matches one of the 32 valid programmed receive destination MAC addresses (defined in the *RAL* and *RAH* registers), if the *Directed Exact Proxying Enable* bit is set in the *Proxying Filter Control (PROXYFC)* register.

| Offset | # of bytes | Field               | Value | Action  | Comment                          |
|--------|------------|---------------------|-------|---------|----------------------------------|
| 0      | 6          | Destination Address |       | Compare | Match any pre-programmed address |

#### 5.6.3.1.2 Directed Multicast Packet

For multicast packets, the upper bits of the incoming packet's destination address index a bit vector, the Multicast Table Array (*MTA*) that indicates whether to accept the packet.

If the *Directed Multicast Wake Up Enable* bit set in the *Wake Up Filter Control (WUFC.MC)* register and the indexed bit in the vector is one, then the I350 generates a wake-up event. If the *Directed Multicast Proxying Enable* bit is set in the *Proxying Filter Control (PROXYFC)* register and the indexed bit in the vector is one, then the I350 forwards packet to Management for Proxying.

**Note:** The exact bits used in the comparison are programmed by software in the *Multicast Offset* field of the *Receive Control (RCTL.MO)* register.

#### 5.6.3.1.3 Broadcast

If the Broadcast Wake Up Enable bit in the *Wake Up Filter Control (WUFC.BC)* register is set, the I350 generates a wake-up event when it receives a broadcast packet. If the Broadcast Proxying Enable bit in the *Proxying Filter Control (PROXYFC)* register is set, the I350 forwards packet to Management for Proxying when receiving a broadcast packet.

| Offset | # of bytes | Field               | Value | Action  | Comment |
|--------|------------|---------------------|-------|---------|---------|
| 0      | 6          | Destination Address | FF*6  | Compare |         |

#### 5.6.3.1.4 Magic Packet

Magic packets are defined in:

[http://www.amd.com/us-en/assets/content\\_type/white\\_papers\\_and\\_tech\\_docs/20213.pdf](http://www.amd.com/us-en/assets/content_type/white_papers_and_tech_docs/20213.pdf) as:

“Once the LAN controller has been put into the Magic Packet mode, it scans all incoming frames addressed to the node for a specific data sequence. This sequence indicates to the controller that this is a Magic Packet frame. A Magic Packet frame must also meet the basic requirements for the LAN technology chosen, such as SOURCE ADDRESS, DESTINATION ADDRESS (which may be the receiving station's IEEE address or a MULTICAST address which includes the BROADCAST address), and CRC. The specific data sequence consists of 16 repetitions of the IEEE address of this node, with no breaks or interruptions. This sequence can be located anywhere within the packet, but must be preceded by a synchronization stream. The synchronization stream allows the scanning state machine to be much simpler. The synchronization stream is defined as 6 bytes of 0xFF. The device will also accept a BROADCAST frame, as long as the 16 repetitions of the IEEE address match the address of the machine to be awakened.”

The I350 expects the destination address to either:

- Be the broadcast address (FF.FF.FF.FF.FF.FF)
- Match the value in Receive Address 0 (*RAH0*, *RAL0*) register. This is initially loaded from the EEPROM but can be changed by the software device driver.
- Match any other address filtering (*RAH[n]*, *RAL[n]*) enabled by the software device driver.

The I350 searches for the contents of Receive Address 0 (*RAH0*, *RAL0*) register as the embedded IEEE address. It considers any non-0xFF byte after a series of at least 6 0xFFs to be the start of the IEEE address for comparison purposes. For example, it catches the case of 7 0xFFs followed by the IEEE address). As soon as one of the first 96 bytes after a string of 0xFFs don't match, it continues to search for another set of at least 6 0xFFs followed by the 16 copies of the IEEE address later in the packet. Note that this definition precludes the first byte of the destination address from being FF.

A Magic Packet's destination address must match the address filtering enabled in the configuration registers with the exception that broadcast packets are considered to match even if the *Broadcast Accept* bit of the *Receive Control (RCTL.BAM)* register is 0b. If APM wake up (wake up by a Magic Packet) is enabled in the EEPROM, the I350 starts up with the Receive Address 0 (*RAH0*, *RAL0*) register loaded from the EEPROM. This enables the I350 to accept packets with the matching IEEE address before the software device driver loads.

**Table 5-6 Magic Packet Structure**

| Offset     | # of bytes | Field                             | Value | Action  | Comment                                                               |
|------------|------------|-----------------------------------|-------|---------|-----------------------------------------------------------------------|
| 0          | 6          | Destination Address               |       | Compare | MAC header – processed by main address filter.                        |
| 6          | 6          | Source Address                    |       | Skip    |                                                                       |
| 12         | S=(0/4)    | Possible VLAN Tag                 |       | Skip    |                                                                       |
| 12 + S     | D=(0/8)    | Possible Length + LLC/SNAP Header |       | Skip    |                                                                       |
| 12 + S + D | 2          | Type                              |       | Skip    |                                                                       |
| Any        | 6          | Synchronizing Stream              | FF*6+ | Compare |                                                                       |
| any+6      | 96         | 16 copies of Node Address         | A*16  | Compare | Compared to Receive Address 0 ( <i>RAH0</i> , <i>RAL0</i> ) register. |

### 5.6.3.1.5 ARP/IPv4 Request Packet

The I350 supports receiving ARP request packets for wake up if the *Directed ARP* bit or the *ARP* bit is set in the *Wake Up Filter Control (WUFC)* register and Proxying if the *Directed ARP* bit or the *ARP* bit is set in the *Proxying Filter Control (PROXYFC)* register.

- If the *Directed ARP* bit is set, a successfully matched packet must contain a broadcast MAC address, match VLAN tag if programmed, a Ethernet type of 0x0806, an ARP op-code of 0x01 and the Target IP address matches one of the four IPv4 addresses programmed in the *IPv4 Address Table (IP4AT)*.
- If the *ARP* bit is set, a successfully matched packet must contain a broadcast MAC address, match VLAN tag if programmed, a Ethernet type of 0x0806 and an ARP op-code of 0x01.

The I350 also handles ARP request packets that have VLAN tagging on both Ethernet II and Ethernet SNAP types.

**Table 5-7 ARP Packet Structure and Processing**

| Offset     | # of bytes | Field                             | Value  | Action  | Comment                                                                                                |
|------------|------------|-----------------------------------|--------|---------|--------------------------------------------------------------------------------------------------------|
| 0          | 6          | Destination Address               |        | Compare | MAC header – processed by main address filter.                                                         |
| 6          | 6          | Source Address                    |        | Skip    |                                                                                                        |
| 12         | S=(0/4)    | Possible VLAN Tag                 |        | Compare | Processed by main address filter.                                                                      |
| 12 + S     | D=(0/8)    | Possible Length + LLC/SNAP Header |        | Skip    |                                                                                                        |
| 12 + S + D | 2          | Ethernet Type                     | 0x0806 | Compare | ARP                                                                                                    |
| 14 + S + D | 2          | HW Type                           | 0x0001 | Compare |                                                                                                        |
| 16 + S + D | 2          | Protocol Type                     | 0x0800 | Compare |                                                                                                        |
| 18 + S + D | 1          | Hardware Size                     | 0x06   | Compare |                                                                                                        |
| 19 + S + D | 1          | Protocol Address Length           | 0x04   | Compare |                                                                                                        |
| 20 + S + D | 2          | Operation                         | 0x0001 | Compare |                                                                                                        |
| 22 + S + D | 6          | Sender HW Address                 | -      | Ignore  |                                                                                                        |
| 28 + S + D | 4          | Sender IP Address                 | -      | Ignore  |                                                                                                        |
| 32 + S + D | 6          | Target HW Address                 | -      | Ignore  |                                                                                                        |
| 38 + S + D | 4          | Target IP Address                 | IP4AT  | Compare | Compare if the <i>Directed ARP</i> bit is set to 1b.<br>May match any of four values in <i>IP4AT</i> . |

### 5.6.3.1.6 Directed IPv4 Packet

The I350 supports receiving directed IPv4 packets for wake up if the *IPV4* bit is set in the Wake Up Filter Control (*WUFC*) register and Proxying if the *IPV4* bit is set in the *Proxying Filter Control* (*PROXYFC*) register.

Four IPv4 addresses are supported, which are programmed in the IPv4 Address Table (*IP4AT*). A successfully matched packet must contain the station's MAC address, match VLAN tag if programmed, a Ethernet type of 0x0800, and one of the four programmed IPv4 addresses. The I350 also handles directed IPv4 packets that have VLAN tagging on both Ethernet II and Ethernet SNAP types.

**Table 5-8 IPv4 Packet Structure and Processing**

| Offset     | # of bytes | Field                             | Value  | Action  | Comment                                        |
|------------|------------|-----------------------------------|--------|---------|------------------------------------------------|
| 0          | 6          | Destination Address               |        | Compare | MAC header – processed by main address filter. |
| 6          | 6          | Source Address                    |        | Skip    |                                                |
| 12         | S=(0/4)    | Possible VLAN Tag                 |        | Compare | Processed by main address filter.              |
| 12 + S     | D=(0/8)    | Possible Length + LLC/SNAP Header |        | Skip    |                                                |
| 12 + S + D | 2          | Ethernet Type                     | 0x0800 | Compare | IPv4                                           |
| 14 + S + D | 1          | Version/ HDR length               | 0x4X   | Compare | Check IPv4                                     |
| 15 + S + D | 1          | Type of Service                   | -      | Ignore  |                                                |
| 16 + S + D | 2          | Packet Length                     | -      | Ignore  |                                                |
| 18 + S + D | 2          | Identification                    | -      | Ignore  |                                                |
| 20 + S + D | 2          | Fragment Info                     | -      | Ignore  |                                                |
| 22 + S + D | 1          | Time to live                      | -      | Ignore  |                                                |

**Table 5-8 IPv4 Packet Structure and Processing (Continued)**

| Offset     | # of bytes | Field                  | Value | Action  | Comment                                |
|------------|------------|------------------------|-------|---------|----------------------------------------|
| 23 + S + D | 1          | Protocol               | -     | Ignore  |                                        |
| 24 + S + D | 2          | Header Checksum        | -     | Ignore  |                                        |
| 26 + S + D | 4          | Source IP Address      | -     | Ignore  |                                        |
| 30 + S + D | 4          | Destination IP Address | IP4AT | Compare | May match any of four values in IP4AT. |

### 5.6.3.1.7 Directed IPv6 Packet

The I350 supports receiving directed IPv6 packets for wake up if the *IPV6* bit is set in the *Wake Up Filter Control (WUFC)* register and Proxying if the *IPV6* bit is set in the *Proxying Filter Control (PROXYFC)* register.

One IPv6 address is supported and is programmed in the *IPv6 Address Table (IP6AT)*. A successfully matched packet must contain the station's MAC address, match VLAN tag if programmed, a Ethernet type of 0x86DD, and the programmed IPv6 address. In addition, the *IPAV.V60* bit should be set. The I350 also handles directed IPv6 packets that have VLAN tagging on both Ethernet II and Ethernet SNAP types.

**Table 5-9 IPv6 Packet Structure and Processing**

| Offset     | # of bytes | Field                             | Value  | Action  | Comment                                        |
|------------|------------|-----------------------------------|--------|---------|------------------------------------------------|
| 0          | 6          | Destination Address               |        | Compare | MAC header – processed by main address filter. |
| 6          | 6          | Source Address                    |        | Skip    |                                                |
| 12         | S=(0/4)    | Possible VLAN Tag                 |        | Compare | Processed by main address filter.              |
| 12+ S      | D=(0/8)    | Possible Length + LLC/SNAP Header |        | Skip    |                                                |
| 12 + S + D | 2          | Ethernet Type                     | 0x86DD | Compare | IPv6                                           |
| 14 + S + D | 1          | Version/ Priority                 | 0x6X   | Compare | Check IPv6                                     |
| 15 + S + D | 3          | Flow Label                        | -      | Ignore  |                                                |
| 18 + S + D | 2          | Payload Length                    | -      | Ignore  |                                                |
| 20 + S + D | 1          | Next Header                       | -      | Ignore  |                                                |
| 21 + S + D | 1          | Hop Limit                         | -      | Ignore  |                                                |
| 22 + S + D | 16         | Source IP Address                 | -      | Ignore  |                                                |
| 38 + S + D | 16         | Destination IP Address            | IP6AT  | Compare | Match value in IP6AT.                          |

### 5.6.3.1.8 NS and MLD IPv6 Packets

The I350 supports receiving:

1. IPv6 Neighbor Solicitation (NS) packets sent by a node to determine the link-layer address of a neighbor, or to verify that a neighbor is still reachable for wake up or Proxying.
2. IPv6 Multicast Listener Discovery (MLD) packets sent by an IPv6 router to discover the presence of multicast listeners (that is, nodes wishing to receive multicast packets) on its directly attached links, and to discover specifically which multicast addresses are of interest to those neighboring nodes.
3. Other ICMPv6 packets.

If the *NS* or *NS Directed* bits are set in the *Wake Up Filter Control (WUFC)* register, Wake up is executed on reception of the relevant ICMPv6 packets. Else if the *NS* or *NS Directed* bits are set in the *Proxying Filter Control (PROXYFC)* register the relevant ICMPv6 packets are sent to Firmware for Protocol offload.

- If the *NS directed* bit is set a successfully matched packet must contain the station's MAC address (Unicast or Multicast), match VLAN tag if programmed, a Ethernet type of 0x86DD, a IPv6 Header Type of ICMPv6 (0x3A), correct ICMPv6 Checksum and the single programmed IPv6 address in the *IPv6 Address Table (IP6AT)* must match the Target IPv6 Address in a NS packet or the Multicast Address field in a MLD packet. In addition, the *IPAV.V60* bit should be set.
- If the *NS* bit is set a successfully matched packet must contain the station's MAC address (Unicast or Multicast), match VLAN tag if programmed, a protocol type of 0x86DD, a IPv6 Header Type of ICMPv6 (0x3A) and a correct ICMPv6 Checksum. In this case all ICMPv6 packets are forwarded to Firmware.

The I350 also handles Neighbor Solicitation (NS) and Multicast Listener Discovery (MLD) IPv6 packets that have VLAN tagging on both Ethernet II and Ethernet SNAP types.

**Table 5-10 Neighbor Solicitation (NS) and Multicast Listener Discovery (MLD) Packet Structure and Processing**

| Offset               | # of bytes | Field                                | Value                          | Action  | Comment                                                                                                    |
|----------------------|------------|--------------------------------------|--------------------------------|---------|------------------------------------------------------------------------------------------------------------|
| 0                    | 6          | Destination Address                  |                                | Compare | MAC header – processed by main address filter.                                                             |

### 5.6.3.2 Flexible Filters

The I350 supports a total of 8 flexible filters. Each filter can be configured to recognize any arbitrary pattern within the first 128 bytes of the packet. To configure the flexible filters, software programs the mask values (required values and the minimum packet length), into the Flexible Host Filter Table (*FHFT* and *FHFT\_EXT*). These 8 flexible filters contain separate values for each filter.

To enable Wake on LAN operation based on the Flex filters Software must also enable the filters in the *Wake Up Filter Control* (*WUFC*) register, and enable the overall wake up functionality. The overall wake up functionality must be enabled by setting *PME\_En* bit in the *PMCSR* configuration register or the *PME\_En* bit in the *Wake Up Control* (*WUC*) register.

To enable Proxying operation based on the Flex filters Software must also enable the filters in the *Proxying Filter Control* (*PROXYFC*) register, and enable the overall Proxying functionality by setting to 1b the *WUC.PPROXYE* bit.

Once enabled, the flexible filters scan incoming packets for a match. If the filter encounters any byte in the packet where the mask bit is one and the byte doesn't match the value programmed in the Flexible Host Filter Table (*FHFT* or *FHFT\_EXT*), then the filter fails that packet. If the filter reaches the required length without failing the packet, it passes the packet and generates a wake-up event. It ignores any mask bits set to one beyond the required length.

**Note:** The flex filters are temporarily disabled when read from or written to by the host. Any packet received during a read or write operation is dropped. Filter operation resumes once the read or write access completes.

The following packets are listed for reference purposes only. The flexible filter could be used to filter these packets.

#### 5.6.3.2.1 IPX Diagnostic Responder Request Packet

An IPX diagnostic responder request packet must contain a valid MAC address, a Ethernet type of 0x8137, and an IPX diagnostic socket of 0x0456. It might include LLC/SNAP headers and VLAN tags. Since filtering this packet relies on the flexible filters, which use offsets specified by the operating system directly, the operating system must account for the extra offset LLC/SNAP headers and VLAN tags.

**Table 5-11 IPX Diagnostic Responder Request Packet Structure and Processing**

| Offset     | # of bytes | Field                             | Value  | Action  | Comment |
|------------|------------|-----------------------------------|--------|---------|---------|
| 0          | 6          | Destination Address               |        | Compare |         |
| 6          | 6          | Source Address                    |        | Skip    |         |
| 12         | S=(0/4)    | Possible VLAN Tag                 |        | Skip    |         |
| 12+ S      | D=(0/8)    | Possible Length + LLC/SNAP Header |        | Skip    |         |
| 12 + S + D | 2          | Ethernet Type                     | 0x8137 | Compare | IPX     |
| 14 + S + D | 16         | Some IPX Stuff                    | -      | Ignore  |         |
| 30 + S + D | 2          | IPX Diagnostic Socket             | 0x0456 | Compare |         |

#### 5.6.3.2.2 Directed IPX Packet

A valid directed IPX packet contains the station's MAC address, a Ethernet type of 0x8137, and an IPX node address that is equal to the station's MAC address. It might include LLC/SNAP headers and VLAN tags. Since filtering this packet relies on the flexible filters, which use offsets specified by the operating system directly, the operating system must account for the extra offset LLC/SNAP headers and VLAN tags.

**Table 5-12 IPX Packet Structure and Processing**

| Offset     | # of bytes | Field                             | Value             | Action  | Comment                                        |
|------------|------------|-----------------------------------|-------------------|---------|------------------------------------------------|
| 0          | 6          | Destination Address               |                   | Compare | MAC header – processed by main address filter. |
| 6          | 6          | Source Address                    |                   | Skip    |                                                |
| 12         | S=(0/4)    | Possible VLAN Tag                 |                   | Skip    |                                                |

### 5.6.3.2.3 Utilizing Flex Wake-Up Filters In Normal Operation

The I350 enables utilizing the WoL Flex filters in normal operation, when in D0 power management state, for queuing decisions. Further information can be found in [Section 7.1.2.6](#).

### 5.6.3.3 Wake Up Packet Storage

The I350 saves the first 128 bytes of the wake-up packet in its internal buffer, which can be read through the *Wake Up Packet Memory (WUPM)* register after the system wakes up.

## 5.6.4 Wake-up and Virtualization

When operating in a virtualized environment, all wake-up capabilities are managed by a single entity (such as the VMM or an IOVM). In an IOV architecture, the physical (PF) driver controls wake-up and none of the Virtual Machines (VMs) has direct access to the wake-up registers. The wake-up registers are not replicated per VF.

## 5.7 Protocol Offload (Proxying)

In order to avoid spurious wake up events and reduce system power consumption when the device is in D3 low power state and system is in S3 or S4 low power states the I350 supports protocol offload (Proxying) of:

1. A single IPv4 ARP (Address Resolution Protocol) request per function.
  - Responds to IPv4 address resolution request with the Host MAC (L2) address (as defined in RFC 826).
2. Two IPv6 NS (Neighbor Solicitation) requests per function, where each NS protocol offload request includes 2 IPv6 addresses, for a total of 4 possible IPv6 addresses per function.

- Responds to IPv6 Neighbor Solicitation requests with the Host MAC (L2) address (as defined in RFC 4861).
- 3. When NS (Neighbor Solicitation) Protocol offload is enabled the I350 supports up to two IPv6 Multicast-Address-Specific MLD (Multicast Listener Discovery) Queries (either MLDv1 or MLDv2) per function. In addition the I350 will also respond to General MLD Queries, used to learn which IPv6 multicast addresses have listeners on an attached link.
  - MLD protocol offload is supported when NS protocol offload is enabled so that IPv6 routers will discover the presence of multicast listeners (that is, nodes wishing to receive multicast packets), for packets with the IPv6 NS “solicited-node multicast address” and continue forwarding these Neighbor Solicitation (NS) requests on the link.
  - MLD Protocol offload is supported for either “MLD Multicast Listener Query packets” or “MLD Multicast Address and Source Specific Query” packets that check for IPv6 Multicast Listeners with the “solicited-node multicast address” placed in the IPv6 destination address field of the IPv6 Neighbor Solicitation (NS) packets that are off-loaded by the I350.
  - Responds to the IPv6 MLD (Multicast Listener Discovery) Queries, with the “solicited-node multicast address” placed in the IPv6 destination address field of the IPv6 Neighbor Solicitation (NS) packets that are off-loaded by the I350 (as defined in RFC 2710 and RFC 3810).

In addition when the *PROXYFC.D0\_PROXY* bit is set to 1b, the I350 can support protocol offload when the device is not in the D3 low power state. Enabling this feature will allow system to be in low power S0ix state for longer durations and increase system power saving.

## 5.7.1 Proxying and Virtualization

When operating in a virtualized environment, all proxying capabilities are managed by a single entity (such as the VMM or an IOVM). In an IOV architecture, the physical (PF) driver controls Proxying and none of the Virtual Machines (VMs) has direct access to the Proxying registers. The Proxying registers are not replicated per VF.

## 5.7.2 Protocol Offload Activation in D3

To enable Protocol Offload software device driver should implement the following steps before D3 entry:

1. Read *MANC.MPROXYE* bit to verify that proxying is supported by management.
2. Clear all pending proxy status bits in the Proxying Status (*PROXYS*) register.
3. Program the Proxying Filter Control (*PROXYFC*) register to indicate type of packets that should be forwarded to manageability for proxying and program the necessary data to the IPv4/v6 Address Table (*IP4AT*, *IP6AT*) and the Flexible Host Filter Table (*FHFT*) registers.
4. Set the *WUFC.FW\_RST\_WK* bit to 1b to initiate a wake if firmware reset was issued when in D3 state and proxying information was lost.
5. Take ownership of the Management Host interface semaphore (*SW\_FW\_SYNC.SW\_MNG\_SM* register bit) using the flow defined in [Section 4.7.1](#) to send Protocol Offload information to Firmware.
6. Read and clear the *FWSTS.FWRI* firmware reset indication bit.
  - If a firmware reset was issued as reported in the *FWSTS.FWRI* bit software device driver should clear the bit and then re-initialize the Protocol Offload list even if previously Firmware was configured to keep protocol Offload list on move from D3 to D0 (See *Set Firmware Proxying Configuration Command* in [Section 10.8.2.4.2.2](#)).

7. Verify that the *HICR.En* bit (See [Section 8.22.1.2](#)) is set 1b which indicates that the Shared RAM interface is available.
8. Write proxying information in the shared RAM interface located in addresses 0x8800-0x8EFF using the format defined in [Section 10.8.2.4.2](#). All addresses should be placed in Networking order.
9. Once information is written into the shared RAM software should set the *HICR.C* bit to 1b.
10. Poll the *HICR.C* bit until bit is cleared by Firmware indicating that command was processed and verify that command completed successfully by checking that *HICR.SV* bit was set.
11. Read Firmware response from the Shared RAM to verify that data was received correctly.
12. Return to [8](#). if additional commands need to be sent to Firmware.
13. Release management Host interface semaphore (*SW\_FW\_SYNC.SW\_MNG\_SM* register bit) using the flow defined in [Section 4.7.2](#).
14. Verify that a Firmware reset was not initiated during the Proxying configuration process by reading the *FWSTS.FWRI* firmware reset indication bit. If a firmware reset was initiated Return to [1](#).
15. Set *WUC.PPROXYE* bit to 1b and enable entry into D3 low power state.
16. Once the I350 moves back into D0 state, the Software Device driver needs to clear the *WUC.PPROXYE* bit, *PROXYS* and *PROXYFC* registers until the next time the system moves to a low power state with proxying enabled.
  - On transition from D3 to D0 Firmware may either delete all proxying requirements or not depending on the configuration defined by Software driver via the *Set Firmware Proxying Configuration Command* using the Shared RAM interface (See [Section 10.8.2.4.2.2](#)).

Normally, after enabling wake-up or proxying, system software moves the device to D3 low power state by writing a 11b to the PCI *PMCSR.Power State* field.

Once proxying is enabled by setting the *WUC.PPROXYE* bit to 1b and device is placed in the D3 low power state, the I350 monitors incoming packets, first filtering them according to its standard address filtering method, then filtering them with all of the proxying filters enabled in the *PROXYFC* register. If a packet passes both the standard address filtering and at least one of the enabled proxying filters and does not pass any of the enabled wake-up filters, the I350 will:

1. Execute the relevant Protocol offload for the packet and not forward the packet to the Host.
2. Set one or more bits in the *Proxying Status (PROXYS)* register according to the Proxying filters matched.
  - Note that the I350 sets more than one bit in the *PROXYS* register if a packet matches more than one filter.
3. Will wake the system and forward a packet that matches the proxying filters but can't be supported to the Host for further processing if configured to do so by Software driver via the *Set Firmware Proxying Configuration Command* using the Shared RAM interface (See [Section 10.8.2.4.2.2](#)).

#### Notes:

1. When device is in D3 a packet that matches both one of the enabled Proxying filters as defined in the *PROXYFC* register and one of the enabled Wake-up filters as defined in the *WUFC* register will only wake-up the system and protocol offload (Proxying) will not occur.
2. Protocol Offload is not executed for illegal packets with CRC errors or Checksum errors and the packets are silently discarded.
3. Once a packet that meets the criteria for Proxying is received the I350 should respond to the request after less than 60 Seconds.

### 5.7.3 Protocol Offload Activation in D0

To enable Protocol Offload in D0 software device driver should implement the following steps:

1. Read *MANC.MPROXYE* bit to verify that proxying is supported by management.
2. Clear all pending proxy status bits in the Proxying Status (*PROXYS*) register.
3. Program the Proxying Filter Control (*PROXYFC*) register to indicate type of packets that should be forwarded to manageability for proxying and program the necessary data to the IPv4/v6 Address Table (*IP4AT*, *IP6AT*) and the Flexible Host Filter Table (*FHFT*) registers.
4. Take ownership of the Management Host interface semaphore (*SW\_FW\_SYNC.SW\_MNG\_SM* register bit) using the flow defined in [Section 4.7.1](#) to send Protocol Offload information to Firmware.
5. Verify that the *HICR.En* bit (See [Section 8.22.1.2](#)) is set 1b which indicates that the Shared RAM interface is available.
6. Read and clear the *FWSTS.FWRI* firmware reset indication bit.
  - If a firmware reset was issued as reported in the *FWSTS.FWRI* bit software device driver should clear the bit and then re-initialize the Protocol Offload list even if previously Firmware was configured to keep protocol Offload list on move from D3 to D0 (See *Set Firmware Proxying Configuration Command* in [Section 10.8.2.4.2.2](#)).
7. Write proxying information in shared RAM interface located in addresses 0x8800-0x8EFF using the format defined in [Section 10.8.2.4.2](#). All addresses should be placed in Networking order.
8. Once information is written into the shared RAM software should set the *HICR.C* bit to 1b.
9. Poll the *HICR.C* bit until bit is cleared by Firmware indicating that command was processed and verify that command completed successfully by checking that *HICR.SV* bit was set.
10. Read Firmware response from the Shared RAM to verify that data was received correctly.
11. Return to [9](#). if additional commands need to be sent to Firmware.
12. Release management Host interface semaphore (*SW\_FW\_SYNC.SW\_MNG\_SM* register bit) using the flow defined in [Section 4.7.2](#).
13. Verify that a Firmware reset was not initiated during the Proxying configuration process by reading the *FWSTS.FWRI* firmware reset indication bit. If a firmware reset was initiated Return to [1](#).
14. Set the *PROXYFC.D0\_PROXY* bit to 1b.
15. Set *WUC.PPROXYE* bit to 1b to enable protocol offload.

Once proxying is enabled in D0 by setting both the *WUC.PPROXYE* bit to 1b and the *PROXYFC.D0\_PROXY* bit to 1b, the I350 monitors incoming packets, first filtering them according to the standard address filtering method and then filtering them according to the proxying filters enabled in the *PROXYFC* register. If a packet passes both the standard address filtering and at least one of the enabled proxying filters then the I350 will:

1. Execute the relevant Protocol offload for the packet and not forward the packet to the Host.
2. Set one or more bits in the *Proxying Status (PROXYS)* register according to the Proxying filter that detected a match.
  - Note that the I350 sets more than one bit in the *PROXYS* register if a packet matches more than one filter.
3. Discard silently illegal packets with CRC errors or Checksum errors without implementing the Protocol offload.
4. Forward a packet that matches the proxying filters but can't be supported by Firmware to the Host for further processing, if configured to do so by Software driver via the *Set Firmware Proxying Configuration Command* using the Shared RAM interface (See [Section 10.8.2.4.2.2](#)).

## 5.8 DMA Coalescing

The I350 supports DMA Coalescing to enable synchronizing port activity and optimize power management of memory, CPU and RC internal circuitry. When conditions to enter DMA coalescing operating mode as defined in [Section 5.8.2](#) exist, the I350 will:

- Stop initiation of any activity on the PCIe link.
- Data received from the Ethernet Link is buffered in internal Receive buffer.
- When executing DMA coalescing, once internal TX buffer is empty, the internal RX buffer watermark for transmission of XOFF flow control packets on the network is defined by the *FCRTC.RTH\_Coal* threshold field.

The I350 will exit DMA coalescing once the conditions defined in [Section 5.8.3](#), to exit DMA coalescing, exist.

### 5.8.1 DMA Coalescing Activation

To activate DMA coalescing functionality software driver should program the following fields:

1. *DMACR.DMACTHR* field to set the receive threshold that causes move out of DMA Coalescing operating mode. Receive watermark programmed should take into account latency tolerance reported (See [Section 5.9](#)) and L1 to L0 latency to avoid Receive Buffer overflow when DMA Coalescing is enabled.
2. *DMCTXTH.DMCTTHR* field to set transmit threshold that causes move out of DMA Coalescing operating mode. Transmit watermark programmed should take into account latency tolerance reported (See [Section 5.9](#)) and L1 to L0 latency to allow transmission of back to back packets when DMA Coalescing is enabled.
3. *DMACR.DMACWT* field that defines a maximum timeout value for:
  - a. A receive packet to be stored in the internal receive buffer before the I350 moves packet to Host memory.
  - b. Fetch the transmit descriptors and transmit data from Host memory once on-chip transmit tail pointer was updated.
  - c. Time to delay an interrupt that is not defined as an immediate interrupt in the *IMIR[n]*, *IMIREXT[n]* or *IMIRVP* registers, when other conditions specified in [Section 5.8.3](#) to exit DMA coalescing do not exist.

— Each time the I350 enters DMA coalescing, internal DMA coalescing watchdog timer is re-armed with the value placed in the *DMACR.DMACWT* field. When in DMA coalescing the internal watchdog timer starts to count when one of the following conditions occurs:

  - A RX packet is received in the Internal buffer.
  - An Interrupt is pending.
  - A descriptor write-back is pending.
  - On-chip transmit tail pointer was updated.

Once interval defined in the *DMACR.DMACWT* field has passed, the I350 exits DMA coalescing and internal buffers, pending interrupts and pending descriptor write-backs are flushed.

— The *DMACR.DC\_LPBKW\_EN* and *DMACR.DC\_BMC2OSW\_EN* bits define if a VM to VM loopback traffic or a BMC to OS traffic is delayed by the time defined in the *DMACR.DMACWT* field when the I350 is in DMA coalescing state or if the traffic causes immediate exit out of DMA coalescing.
4. *DMCTLX.TTLX* timer field to define:

- a. The time between detection of DMA idle status to actual move into low power link state (L0s or L1). Value programmed in this register reduces amount of entries into low power PCIe link state when traffic rate is high.
  - Even when DMA coalescing is disabled (*DMACR.DMAC\_EN* = 0) entry into low power link state when no DMA activity is expected, will be delayed according to value placed in *DMCTLX.TTLX* field.
- b. The time between detection of DMA idle condition and entry into DMA coalescing state. To limit entry into DMA coalescing state when packet rate is high.
5. *DMCTLX.DCFLUSH\_DIS* to define if pending descriptor write-back flush and pending interrupt flush should occur before entry into DMA coalescing state.
  - When *DMCTLX.DCFLUSH\_DIS* is set to 1b any pending interrupts or descriptor write-back operations do not cause the I350 to move out of DMA coalescing state.
6. *DMCTLX.DC\_FLUSH* to define when pending descriptor write-back flush, pending interrupt flush, entry into DMA coalescing state and moving PCIe link into low power Lx state occurs relative to the *DMCTLX.TTLX* timer activation and expiration (See [Section 8.24.1](#) for further information).
7. *DMCRTRH.UTRESH* low rate threshold field to define a minimum RX data rate. Below this data rate the I350 does not enter DMA coalescing operating mode if value of field is greater than 0.
  - a. This field prevents moving into DMA coalescing operating mode in current time window when traffic in the previous time window is sparse and effectiveness of DMA coalescing on system power saving is limited. After reception is enabled, if value of this field is greater than 0, the I350 does not enter DMA coalescing operating mode until duration of at least one time window has passed, to allow for collection of enough statistical data on receive data rate.
  - b. The time window to measure data rate is defined according to the port link rate (10Mbps, 100Mbps or 1Gbps), *SCCRL.INTERVAL* field and the *SCBI.BI* field. The Port link rate and the *SCBI.BI* value define a basic interval that's multiplied by the *SCCRL.INTERVAL* to define the time window.  
 For example to disable entry into DMA coalescing operating mode so long as data rate is below 1 Mbyte/s when port speed is 1Gbps the following values can be programmed:
    - *SCBI.BI* = 0xC35000 (defines basic interval of 2.048 msec at 1Gbps link rate).
    - *SCCRL.INTERVAL* = 0x3E8 (The *SCCRL.INTERVAL* decimal value of 1,000 multiplied by the 2.048 msec basic interval defined in the *SCBI.BI* field equals a time window of 2.048 seconds).
    - *DMCRTRH.UTRESH* = 0x7D00 (The *DMCRTRH.UTRESH* decimal value of 32,000 multiplied by 64 Byte chunks equals 2,048,000 Bytes of data. This defines the minimum amount of data to be received in the 2.048 second time window before DMA coalescing is activated in the next time window. As a result at least 1 Mbyte per second data rate needs to be received before entry into DMA coalescing operating mode is enabled).
  - c. The time window is also used for Storm Control, see [Section 7.8.3.8.4.2](#) for further information on how to set the time window.
8. *FCRTC.RTH\_Coal* field that defines a flow control receive high watermark for sending flow control packets. The I350 uses the *FCRTC.RTH\_Coal* threshold when:
  - Flow control is enabled by setting the *CTRL.TFCE* bit.
  - The I350 is in DMA Coalescing mode.
  - Internal transmit buffer is empty.
9. *SRRCTL[n].DMACQ\_Dis* bit to define high priority queues. When a received packet is forwarded to a queue with the *SRRCTL[n].DMACQ\_Dis* bit set, the I350 moves immediately out of DMA Coalescing mode and executes a DMA operation to store the packet in host memory.
10. *DMACR.DMAC\_EN* bit should be set to 1 to enable activation of DMA Coalescing operating mode.
11. *DMACR.DMAC\_Lx* to 10b or 11b to define that low power L1 PCIe ASPM link state is entered when in DMA Coalescing operating mode.

#### Notes:

1. The values of *DMACR.DMACTHR* and *FCRTC.RTH\_Coal* should be set so that XOFF packet generation is avoided. In DMA Coalescing mode, when transmit buffer is empty, the XOFF flow control threshold (*FCRTC.RTH\_Coal*) value can be increased by maximum jumbo frame size compared to normal operation, where high threshold is set by the *FCRTH0* register.
2. When entering DMA coalescing mode, the value written in the *FCRTH0* register is used to generate XOFF flow control frames until the internal transmit buffer is empty. Once the internal transmit buffer is empty the value written in the *FCRTC.RTH\_Coal* field is used as a watermark for generation of XOFF flow control frames.
3. When *PCIEMISC.Lx\_decision* bit is set to 1, the I350 transitions the PCIe link into low power state as defined in the *DMACR.DMAC\_Lx* field once it detects no PCIe activity for a duration defined in the *DMCTLX.TTLX* field. However, when entry to the L0s state is enabled in the PCIe configuration *Link Control Register* (See [Section 9.5.6.8](#)), the I350 will always enter the L0s state after the duration defined in the *Latency\_To\_Enter\_L0s* field (if not already in L1, L2 or L3 low power link state) to comply with the PCIe specification.

## 5.8.2 Entering DMA Coalescing Operating Mode

Enabling DMA Coalescing operation by setting the *DMACR.DMAC\_EN* bit to 1, enables alignment of bus master traffic and interrupts from all ports. Power saving is achieved since synchronizing PCIe accesses between ports increases the occurrence of idle intervals on the PCIe bus and also increases the duration of these idle intervals. Power Management Unit on platform can utilize these Idle intervals to reduce system power.

### 5.8.2.1 Entering DMA Coalescing

The I350 will enter DMA coalescing when all of the following conditions exist:

1. DMA Coalescing is enabled (*DMACR.DMAC\_EN* = 1).
2. Internal Receive buffers are empty.
3. There are no pending DMA operations.
4. None of the conditions defined in [Section 5.8.3.1](#) to move out of DMA Coalescing exist.

Before entering the DMA coalescing power saving mode, if the *DMCTLX.DCFLUSH\_DIS* bit is programmed to 0, the I350 will:

- Flush all pending interrupts that were delayed due to the Interrupt Throttling (ITR) mechanism.
- The I350 will flush all pending Receive descriptor and Transmit descriptor write backs and pre-fetch available Receive descriptors and Transmit descriptors to internal cache.

**Note:** Timing of pending interrupts and Pending descriptor write-back flush operation relative to the expiration of the *DMCTLX.TTLX* timer is defined by the *DMCTLX.DC\_FLUSH* bit (See [Section 8.24.3](#)).

## 5.8.3 Conditions to Exit DMA Coalescing

### 5.8.3.1 Exiting DMA Coalescing

When the I350 is in DMA Coalescing operating mode, DMA Coalescing mode is exited when one of the following events occurs:

1. Amount of data in internal receive buffer passed the *DMACR.DMACTHR* threshold.
2. Empty space in internal transmit buffer is above the value defined in *DMCTXTH.DMCTTHR* field and available transmit descriptors exist.
3. A high priority packet was received (See [Section 7.3.6](#) for definition of high priority packets). A high priority packet is a packet that generates an immediate interrupt, as defined in the *IMIR[n]*, *IMIREXT[n]* or *IMIRVP* registers.
4. A received packet destined to a high priority queue (*SRRCTL[n].DMACQ\_Dis* = 1b) was detected.
5. DMA coalescing Watchdog timer defined in the *DMACR.DMACWT* field expires as a result of the following occurrences not being serviced for the duration defined in the *DMACR.DMACWT* field:
  - A RX packet was received in the Internal buffer.
  - An Interrupt is pending.
  - A descriptor write-back is pending.
  - On-chip transmit tail pointer was updated.
6. Received data rate detected is lower than defined in the *DMCRTRH.UTRESH* field.
7. DMA Coalescing is disabled (*DMACR.DMAC\_EN* = 0).
8. Another the I350 function initiated a transaction on the PCIe bus.
9. Updated PCIe LTR message with reduced latency tolerance value needs to be sent (See [Section 5.9](#) for additional information on LTR).
  - The I350 does not exit DMA coalescing to send a PCIe LTR message with increased latency tolerance.
10. Software initiates move out of DMA Coalescing by writing 1b to the *DMACR.EXIT\_DC* self clearing bit.
11. VM to VM loopback traffic if the *DMACR.DC\_LPBKW\_EN* bit is programmed to 0b.
12. BMC to OS traffic if the *DMACR.DC\_BMC2OSW\_EN* bit is programmed to 0b.

#### Notes:

1. Even when conditions for DMA Coalescing do not exist, the I350 will continue to be in low power PCIe link state (L0s or L1) if there is no requirement for PCIe access.
2. If PCIe PME wake message needs to be sent, PCIe link will move from L1 low power state to L0 to send the message but DMA will remain in DMA coalescing state.
3. Pending interrupts or pending descriptor write-back operations do not cause the I350 to move out of DMA coalescing state.

## 5.9 Latency Tolerance Reporting (LTR)

The I350 generates PCIe LTR messages to report service latency requirements for memory reads and writes to the Root Complex for system power management.

The I350 will report either minimum latency tolerance, maximum latency tolerance or no latency tolerance requirements as a function of link, LAN port and function status. Minimum and maximum latency tolerance values are programmed in the *LTRMINV* and *LTRMAXV* registers respectively per PF by the software driver to optimize power consumption without incurring packet loss due to receive buffer overflow.

## 5.9.1 Latency Tolerance Reporting Algorithm

The I350 sends LTR messages according to the following algorithm when the capability is enabled in the Latency Tolerance Reporting (LTR) Capability structure of Function 0 located in PCIe configuration space:

1. When Links on all ports are disconnected or all LAN ports are disabled (transmit and receive activity not enabled) and the *LTRC.LNKDLS\_EN* and *LTRC.PDLS\_EN* bits are set respectively, the I350 will send a LTR PCIe message with LTR Requirement bits cleared, to indicate that no Latency tolerance requirements exists.
2. If the I350 reported following PCIe link-up latency tolerance requirements with any requirement bit set in the PCIe LTR message and all enabled functions were placed in D3 low power state via the *PMCSR* register, the I350 will send a new LTR Message with all the Requirement bits clear.
3. If the I350 reported following PCIe link-up latency tolerance requirements with any requirement bit set and the LTR Mechanism Enable bit in the PCIe configuration space is cleared, the I350 will send a new LTR Message with all the Requirement bits clear.
4. The I350 will send a LTR message with the value placed in the *LTRMAXV* register when either one of following conditions exist:
  - a. Software set the *LTRC.LTR\_MAX* register bit.
  - b. RX EEE LPI state is detected on the Ethernet Link and *LTRC.EEEMS\_EN* is set (See [Section 3.7.7.4](#) for additional information).
5. Otherwise, the I350 will send a LTR message with a minimum value.

**Note:** In all cases maximum LTR Value sent by the I350 does not exceed the maximum latency values in the *Max No-Snoop Latency* and *Max Snoop Latency* Registers in the Latency Tolerance Reporting (LTR) Capability structure of Function 0.

Figure 5-7 describes the I350 LTR message generation flow.

**Figure 5-7** PCIe LTR Message Generation Flow per Function

## 5.9.2 Latency Tolerance Reporting Per Function

Internal to the I350 each function can request to generate a Minimum value LTR, a Maximum value LTR and a LTR message with the Requirement bits cleared. The I350 conglomerates latency requirements from the functions that have LTR messaging enabled and sends a single LTR message in the following manner:

- The acceptable latency values for the message sent upstream by the I350 must reflect the lowest latency tolerance values associated with any function.
  - It is permitted that the Snooped and Non-Snooped values reported in the conglomerated message are associated with different functions.
  - If none of the functions have a Latency requirement for a certain type of traffic (Snoop/Non-snoop), the message sent by the I350 will not have the Requirement bit corresponding to that type of traffic set.
- The I350 transmits a new LTR message upstream when the capability is enabled and when any function changes the values it has reported internally in such a way as to change the conglomerated value reported previously by the I350.

Each function in the I350 reports support of LTR messaging in the configuration space by:

- Setting the *LTR Mechanism Supported* bit in the *PCIe Device Capabilities 2* configuration register (Support defined by *LTR\_EN* bit in *Initialization Control Word 1* EEPROM word, that controls enabling of the LTR structures).
- Supporting the *Latency Tolerance Requirement Reporting (LTR) Capability* structure in the PCIe configuration space.

To enable generation of LTR messages by a function the *LTR Mechanism Enable* bit in the *Device Control 2* configuration register of Function 0 should be set.

**Note:** A function that does not have LTR messaging enabled is considered a function that does not have any Latency Tolerance requirements.

### 5.9.2.1 Conditions for Generating LTR Message with the Requirement Bits Cleared

When LTR messaging is enabled the I350 functions will send a LTR message with the Requirement bits cleared in the following cases:

1. Following PE\_RST\_N assertion (PCIe reset) after LTR capability is enabled.
2. LAN port is disabled (both *RCTL.RXEN* and *TCTL.EN* are cleared), receive buffer is empty and *LTTRC.PDLS\_EN* is set.
3. LAN port is disconnected, BMC to Host traffic is disabled (*MANC.EN\_BMC2HOST* = 0) and *LTTRC.LNKDLS\_EN* is set.
4. Function is not in D0a state.
5. When the LSNP and LNSNP bits are cleared in the *LTRMINV* register and minimum LTR value needs to be sent.
6. When the LSNP and LNSNP bits are cleared in the *LTRMAXV* register and maximum LTR value needs to be sent.
7. When the *LTR Mechanism Enable* bit in the *Device Control 2* configuration register of Function 0 was cleared and the I350 sent previously a LTR message with Requirement bits set.

When one of the above conditions exist in all functions that are enabled, the I350 will send a LTR message with the requirement bits cleared.

**Note:** A disabled function does not generate Latency Tolerance requirements.

### 5.9.2.2 Conditions for Generating LTR Message with Maximum LTR Value

When LTR messaging is enabled and conditions to send LTR Message with Valid bits cleared do not exist, the I350 functions will send a maximum value LTR message, with the values programmed in the *LTRMAXV* register in the following cases:

1. Following a software write 1 operation to *LTRC.LTR\_MAX* bit and the last PCIe LTR message sent had a latency tolerance value different then the value specified in the *LTRMAX* register.
2. RX EEE LPI state is detected on the Ethernet Link and *LTRC.EEEMS\_EN* is set.
3. When updated data was written to the *LTRMAXV* register and conditions defined in 1. or 2. to send a LTR message with a maximum value exists.

When one of the above conditions exist in all functions that are enabled and at least in one enabled function conditions to send a LTR message with requirement bits cleared (See [Section 5.9.2.1](#)) doesn't exist, the I350 will send a LTR message with the values programmed in the *LTRMAXV* register.

**Note:** When the *LTRC.LTR\_MAX* bit is cleared, the I350 will send a LTR message with the value placed in the *LTRMINV* register, if the value is smaller than the value placed in the *LTRMAXV* register.

### 5.9.2.3 Conditions for Generating LTR Message with Minimum LTR Value

When LTR messaging is enabled, the I350 functions will send a minimum value LTR message, with the values programmed in the *LTRMINV* register in the following cases:

1. Following a software write 1 operation to the *LTRC.LTR\_MIN* bit and the last PCIe LTR message sent had a latency tolerance value different then the value specified in the *LTRMINV* register.
2. When updated data was written to the *LTRMINV* register and conditions to send LTR message with the Requirement bits cleared (See [Section 5.9.2.1](#)) or Maximum value LTR (See [Section 5.9.2.2](#)) do not exist.

**Note:** If a LTR message that indicates that best possible service is requested needs to be sent, the *Latency Tolerance value* in the *LTRMINV* and *LTRMAXV* registers should be programmed to 0 with the appropriate *requirement* bits set. In this case the I350 will send a LTR message with both the value and scale fields cleared to 0's.

**NOTE:**      *This page intentionally left blank.*

## 6 Non-Volatile Memory Map - EEPROM

### 6.1 EEPROM General Map

The I350 EEPROM is partitioned into 4 main blocks followed by Firmware and PXE structures. First 128 word section is allocated to words common to all LAN ports, Firmware, Software, PXE and LAN port 0. Following 64 word sections are allocated to Lan port 1, Lan port 2 and Lan port 3 as shown in [Table 6-1](#).

A detailed list of EEPROM words loaded by Hardware following Power-up, Hardware reset or software generated resets (*CTRL.RST*, *CTRL\_EXT.EE\_RST* or *CTRL.DEV\_RST*) can be found in the auto load sequence table in [Section 3.3.1.3](#).

**Table 6-1 EEPROM Top Level Partitioning**

| EEPROM Word Offsets | Partition                                                                                |
|---------------------|------------------------------------------------------------------------------------------|
| 0x00 to 0x7F        | Common Words (PCIe, PXE, SW and FW) and LAN port 0 words - see <a href="#">Table 6-2</a> |
| 0x80 to 0xBF        | LAN Port 1 words - see <a href="#">Table 6-3</a>                                         |
| 0xC0 to 0xFF        | LAN Port 2 words - see <a href="#">Table 6-3</a>                                         |
| 0x100 to 0x13F      | LAN Port 3 words - see <a href="#">Table 6-3</a>                                         |
| 0x140...            | Option ROM and Firmware Structures                                                       |

[Table 6-2](#) lists the I350 EEPROM word map for Common words and Lan Port 0.

**Table 6-2 Common and LAN Port 0 EEPROM Map**

| EEPROM Word Offsets | Used By/In | High Byte                                                                                     | Low Byte | Which LAN |

[Table 6-3](#) maps the I350 EEPROM words that can hold different content for LAN Ports 0, 1, 2 and 3. Addresses listed in the table are an offset from the LAN Base address of the relevant EEPROM LAN section. EEPROM LAN Base addresses of the LAN ports are as follows:

- LAN Port 0 EEPROM section Base Address - 0x0
- LAN Port 1 EEPROM section Base Address - 0x80
- LAN Port 2 EEPROM section Base Address - 0xC0
- LAN Port 3 EEPROM section Base Address - 0x100

## 6.2 Hardware Accessed Words

This section describes the EEPROM words that are loaded by the I350 hardware. Most of these bits are located in configuration registers. The words are only read and used if the signature field in the *EEPROM Sizing and Protected Fields* EEPROM word (word 0x12) is valid.

**Note:** When **Word** is mentioned before an EEPROM address, address is the absolute address in the EEPROM. When **Offset** is mentioned before an EEPROM address, the address is relative to the start of the relevant EEPROM section.

## 6.2.1 Ethernet Address (LAN Base Address + Offsets 0x00-0x02)

The Ethernet Individual Address (IA) is a 6-byte field that must be unique for each NIC, and thus unique for each copy of the EEPROM image. The first three bytes are vendor specific. The value from this field is loaded into the Receive Address Register 0 (RAL0/RAH0).

The Ethernet address is loaded for LAN0 from Addresses 0x0 to 0x02 and for LAN 1, 2 and 3 from offsets 0x0 to 0x2 at the start of the relevant sections.

Following table depicts mapping of the Ethernet MAC addresses to the EEPROM words.

| LAN Port | MAC Address       | LAN Base Address + 0x00 | LAN Base Address + 0x01 | LAN Base Address + 0x02 |
|----------|-------------------|-------------------------|-------------------------|-------------------------|
| 0        | 00-A0-C9-00-00-00 | 0xA000                  | 0x00C9                  | 0x0000                  |
| 1        | 00-A0-C9-00-00-01 | 0xA000                  | 0x00C9                  | 0x0100                  |
| 2        | 00-A0-C9-00-00-02 | 0xA000                  | 0x00C9                  | 0x0200                  |
| 3        | 00-A0-C9-00-00-03 | 0xA000                  | 0x00C9                  | 0x0300                  |

## 6.2.2 Initialization Control Word 1 (word 0x0A)

The *Initialization Control Word 1* in the Common section contains initialization values that:

- Set defaults for some internal registers
- Enable/disable specific features
- Determine which PCI configuration space values are loaded from the EEPROM

| Bit  | Name        | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                              |

Loaded to <i>PCIEERRCTL</i> register (refer to <a href="#">Section 8.23.11</a> ).                                                        |
| 13   | LTR_EN      | 1b                          | LTR capabilities reporting enable.<br>0 - Do not report LTR support in the PCIe configuration Device Capabilities 2 register.<br>1 - Report LTR support in the PCIe configuration Device Capabilities 2 register.<br>Defines default setting of LTR capabilities reporting (refer to <a href="#">Section 9.5.6.11</a> ). |
| 12:7 | Reserved    | 0x0                         | Reserved                                                                                                                                                                                                                                                                                                                 |
| 6    | SDP_IDDQ_EN | 0b                          | When set, SDP IOs keep their value and direction when the I350 enters dynamic IDDQ mode either due to PCIe entering Dr state or DEV_OFF_N pin being asserted. Otherwise, SDP IOs moves to HighZ + pull-up mode in dynamic IDDQ mode.                                                                                     |

| Bit | Name                      | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                                                               |
|-----|---------------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | Deadlock Timeout Enable   | 1b                          | If set, a driver granted access to the EEPROM or Flash that does not toggle the EEPROM interface for more than 2 seconds or the FLASH interface for more than 8 seconds will have the grant revoked. Refer to <a href="#">Section 3.3.2.1</a> . This bit also enables <i>EERD</i> and <i>EEMNGCTL</i> timeout if EEPROM is not responding to status read, |
| 4   | LAN PLL Shutdown Enable   | 0b                          | When set, enables shutting down the PHY PLL in low-power states when the Internal PHY is powered down (such as link disconnect). When cleared, the PHY PLL is not shut down in a low-power state.                                                                                                                                                         |
| 3   | Power Management          | 1b                          | 0b = Power Management registers set to read only. In this mode, the I350 does not execute a hardware transition to D3.Reserved<br>1b = Full support for power management (For normal operation, this bit must be set to 1b).<br><a href="#">See section 9.5.1</a> .                                                                                       |
| 2   | DMA clock gating Disabled | 1b                          | When set Disables DMA clock gating power saving mode.                                                                                                                                                                                                                                                                                                     |
| 1   | Load Subsystem IDs        | 1b                          | When this bit is set to 1b the I350 loads its PCIe Subsystem ID and Subsystem Vendor ID from the EEPROM ( <i>Subsystem ID</i> and <i>Subsystem Vendor ID</i> EEPROM words).                                                                                                                                                                               |
| 0   | Load Vendor/Device IDs    | 1b                          | When set to 1b the I350 loads its PCIe Device IDs from the EEPROM ( <i>Device ID</i> or <i>Dummy Device ID</i> EEPROM words) and the PCIe Vendor ID from the EEPROM.                                                                                                                                                                                      |

### 6.2.3 Subsystem ID (Word 0x0B)

If the *Load Subsystem IDs* in *Initialization Control Word 1* EEPROM word is set, the *Subsystem ID* word in the Common section is read in to initialize the PCIe Subsystem ID. Default value is 0x0 (refer to [Section 9.4.14](#)).

### 6.2.4 Subsystem Vendor ID (Word 0x0C)

If the *Load Subsystem IDs* bit in *Initialization Control Word 1* EEPROM word is set, the Subsystem Vendor ID word in the Common section is read in to initialize the PCIe Subsystem Vendor ID. The default value is 0x8086 (refer to [Section 9.4.13](#)).

### 6.2.5 Device ID (LAN Base Address + Offset 0x0D)

If the *Load Vendor/Device IDs* bit in *Initialization Control Word 1* is set, the *Device ID* EEPROM word is read in from the Common, LAN 1, LAN 2 and LAN 3 sections to initialize the Device ID of LAN0, LAN1, LAN2 and LAN3 functions, respectively. The default value in EEPROM-less operation is 0x151F (refer to [Section 9.4.2](#)).

### 6.2.6 Vendor ID (Word 0x0E)

If the *Load Vendor/Device IDs* bit in *Initialization Control Word 1* EEPROM word is set, this word is read in to initialize the PCIe Vendor ID. The default value is 0x8086 (refer to [Section 9.4.1](#)).

**Note:** If a value of 0xFFFF is placed in the *Vendor ID* EEPROM word, the value in the PCIe *Vendor ID* register will return to the default 0x8086 value. This functionality is implemented to avoid a system hang situation.

## 6.2.7 Dummy Device ID (Word 0x1D)

If the *Load Vendor/Device IDs* bit in *Initialization Control Word 1* EEPROM word is set, this word is read in to initialize the Device ID of dummy devices. The default value is 0x10A6 (refer to [Section 9.4.2](#)).

## 6.2.8 Initialization Control Word 2 (LAN Base Address + Offset 0x0F)

The *Initialization Control Word 2* read by the I350, contains additional initialization values that:

- Set defaults for some internal registers
- Enable/disable specific features

| Bit   | Name                    | Default in EEPROM less mode | Description                                                                                                                                                                                              |
|-------|-------------------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15    | APM PME# Enable         | 0b                          | Initial value of the <i>Assert PME On APM Wakeup</i> bit in the Wake Up Control (WUC.APM PME) register. Refer to <a href="#">Section 8.20.1</a> .                                                        |
| 14    | PCS parallel detect     | 1b                          | Enables PCS parallel detect. Mapped to PCS_LCTL.AN TIMEOUT EN bit. Refer to <a href="#">Section 8.17.2</a> .<br>Note: Bit should be 0b only when port operates in SGMII mode (CTRL_EXT.LINK_MODE = 10b). |
| 13:12 | Pause Capability        | 11b                         | Desired pause capability for advertised configuration base page. Mapped to PCS_ANADV.ASM. Refer to <a href="#">Section 8.17.4</a> .                                                                      |
| 11    | ANE                     | 0b                          | Auto-Negotiation Enable<br>Mapped to PCS_LCTL.AN_ENABLE. Refer to <a href="#">Section 8.17.2</a> .<br>Note: Bit should be 0b when port operates in internal copper PHY mode and 1000BASE-KX modes.       |
| 10    | FRCSPEED                | 0b                          | Force Speed<br>Default setting for the <i>Force Speed</i> bit in the Device Control register (CTRL[11]). Refer to <a href="#">Section 8.2.1</a>                                                          |

## 6.2.9 EEPROM Sizing and Protected Fields (Word 0x12)

Provides indication on EEPROM size and protection.

**Note:** If the Enable Protection Bit in this word is set and the signature is valid, the software device driver has read but no write access to this word via the *EEC* and *EERD* registers; In this case, write access is possible only via an authenticated firmware interface.

| Bit           | Name        | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |             |             |                     |               |          |  |       |           |         |       |           |         |       |           |         |

| 15:14         | Signature   |                             | The <i>Signature</i> field indicates to the I350 that there is a valid EEPROM present. If the signature field is 01b, EEPROM read is performed, otherwise the other bits in this word are ignored, no further EEPROM read is performed, and default values are used for the configuration space IDs.                                                                                                                                                                                                                                                                                           |             |             |                     |               |          |  |       |           |         |       |           |         |       |           |         |

## 6.2.11 PCIe L1 Exit latencies (Word 0x14)

| Bits  | Name                   | Default in EEPROM less mode | Description                                                                                                                                                                                                                     |
|-------|------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15    | Reserved               | 1b                          | Reserved                                                                                                                                                                                                                        |
| 14:12 | L1_Act_Acc_Latency     | 110b                        | Loaded to the "Endpoint L1 Acceptable Latency" field in the "Device Capabilities" in the "PCIe configuration registers" at power up.                                                                                            |
| 11:9  | L1 G2 Sep exit latency | 101                         | L1 exit latency G2S. Loaded to "Link Capabilities" -> "L1 Exit Latency" at PCIe v2.1 (5GT/s) system in Separate clock setting.                                                                                                  |
| 8:6   | L1 G2 Com exit latency | 011b                        | L1 exit latency G2C. Loaded to "Link Capabilities" -> "L1 Exit Latency" at PCIe v2.1 (5GT/s) system in Common clock setting.<br><b>Note:</b> Should be set to 101b (16 to 32 $\mu$ s) to reflect an exit time of 17 $\mu$ s     |
| 5:3   | L1 G1 Sep exit latency | 100b                        | L1 exit latency G1S. Loaded to "Link Capabilities" -> "L1 Exit Latency" at PCIe v2.1 (2.5GT/s) system in Separate clock setting.<br><b>Note:</b> Should be set to 101b (16 to 32 $\mu$ s) to reflect an exit time of 17 $\mu$ s |
| 2:0   | L1 G1 Com exit latency | 010b                        | L1 exit latency G1C. Loaded to "Link Capabilities" -> "L1 Exit Latency" at PCIe v2.1 (2.5GT/s) system in Common clock setting.<br><b>Note:</b> Should be set to 101b (16 to 32 $\mu$ s) to reflect an exit time of 17 $\mu$ s   |

## 6.2.12 PCIe Completion Timeout Configuration (Word 0x15)

| Bit  | Name                       | Default in EEPROM less mode | Description                                                                                                                                                                                             |
|------|----------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:5 | Reserved                   |                             | Reserved                                                                                                                                                                                                |
| 4    | Completion Timeout Re-send | 1b                          | When set, enables to re-send a request once the completion timeout expired<br>0b = Do not re-send request on completion timeout.<br>1b = Re-send request on completion timeout. Refer to Section 8.6.1. |
| 3:0  | Reserved                   | 0x0                         | Reserved                                                                                                                                                                                                |

## 6.2.13 MSI-X Configuration (LAN Base Address + Offset 0x16)

These words configure MSI-X functionality for LAN 0, LAN 1, LAN 2 and LAN 3.

| Bit   | Name     | Default in EEPROM less mode | Description                                                                                                                                                                       |
|-------|----------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:11 | MSI_X_N  | 0x9                         | This field specifies the number of entries in MSI-X tables of the relevant LAN. The range is 0-24. MSI_X_N is equal to the number of entries minus one. Refer to Section 9.5.3.3. |
| 10    | MSI Mask | 1b                          | MSI per-vector masking setting. This bit is loaded to the masking bit (bit 8) in the <i>Message Control</i> word of the <i>MSI Configuration Capability structure</i> .           |
| 9:0   | Reserved | 0x0                         | Reserved                                                                                                                                                                          |

## 6.2.14 PCIe Init Configuration 1 (Word 0x18)

This word is used to define L0s exit latencies.

| Bits  | Name                    | Default in EEPROM less mode | Description                                                                                                                                                                           |
|-------|-------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15    | Reserved                | 0b                          | Reserved.                                                                                                                                                                             |
| 14:12 | L0s acceptable latency  | 011b                        | Loaded to the "Endpoint L0s Acceptable Latency" field in the "Device Capabilities" in the "PCIe configuration registers" at power up.                                                 |
| 11:9  | L0s G2 Sep exit latency | 111b                        | L0s exit latency G2S. Loaded to L0s Exit Latency field in the Link Capabilities register in the PCIe configuration registers in PCIe v2.1 (5GT/s) system at Separate clock setting.   |
| 8:6   | L0s G2 Com exit latency | 100b                        | L0s exit latency G2C. Loaded to L0s Exit Latency field in the Link Capabilities register in the PCIe configuration registers in PCIe v2.1 (5GT/s) system at Common clock setting.     |
| 5:3   | L0s G1 Sep exit latency | 111b                        | L0s exit latency G1S. Loaded to L0s Exit Latency field in the Link Capabilities register in the PCIe configuration registers in PCIe v2.1 (2.5GT/s) system at Separate clock setting. |

| Bits | Name                    | Default in EEPROM less mode | Description                                                                                                                                                                         |
|------|-------------------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2:0  | L0s G1 Com exit latency | 011b                        | L0s exit latency G1C. Loaded to L0s Exit Latency field in the Link Capabilities register in the PCIe configuration registers in PCIe v2.1 (2.5GT/s) system at Common clock setting. |

## 6.2.15 PCIe Init Configuration 2 Word (Word 0x19)

This word is used to set defaults for some internal PCIe configuration registers.

| Bit  | Name                 | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                     |

| 12    | Cache_Lsize | 1b                          | Cache Line Size<br>0b = 64 bytes.<br>1b = 128 bytes.<br>This bit defines the Cache line size reported in the PCIe mandatory configuration register area. Refer to <a href="#">Section 9.4.7</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 11:10 | GIO_Cap     | 10b                         | PCIe Capability Version<br>The value of this field is reflected in the two LSBs of the capability version in the PCIe CAP register (config space – offset 0xA2).<br><br>This field must be set to 10b to use extended configuration capability.<br><br>Note that this is not the PCIe version. It is the PCIe capability version. This version is a field in the PCIe capability structure and is not the same as the PCIe version. It changes only when the content of the capability structure changes. For example, PCIe 1.0, 1.0a, and 1.1 all have a capability version of one. PCIe 2.0 has a version of two because it added registers to the capabilities structures. Refer to <a href="#">Section 9.5.6.3</a> . |

## 6.2.18 LED 1,3 Configuration Defaults (LAN Base Address + Offset 0x1C)

These EEPROM words specify the hardware defaults for the *LEDCTL* register fields controlling the LED1 (ACTIVITY indication) and LED3 (LINK\_1000 indication) output behavior. Words control LEDs behavior of LAN 0, LAN 1, LAN 2 and LAN 3 ports.

| Bit   | Name        | Default in EEPROM less mode | Description                                                                                                                                                                                                                                           |
|-------|-------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 11:8  | LED3 Mode   | 0111b                       | Initial value of the <i>LED3_MODE</i> field specifying what event/state/pattern is displayed on LED3 (LINK_1000) output. A value of 0111b (0x7) indicates 1000 Mb/s operation.<br>See <a href="#">Section 8.2.9</a> and <a href="#">Section 7.5</a> . |
| 7     | LED1 Blink  | 1b                          | Initial value of <i>LED1_BLINK</i> field.<br>0b = Non-blinking.<br>See <a href="#">Section 8.2.9</a> and <a href="#">Section 7.5</a> .                                                                                                                |
| 6     | LED1 Invert | 0b                          | Initial value of <i>LED1_IVRT</i> field.<br>0b = Active-low output.<br>See <a href="#">Section 8.2.9</a> and <a href="#">Section 7.5</a> .                                                                                                            |
| 5:4   | Reserved_1  | 11b                         | Value should be 11b.                                                                                                                                                                                                                                  |
| 3:0   | LED1 Mode   | 0011b                       | Initial value of the <i>LED1_MODE</i> field specifying what event/state/pattern is displayed on LED1 (ACTIVITY) output. A value of 0011b (0x3) indicates the ACTIVITY state.<br>See <a href="#">Section 8.2.9</a> and <a href="#">Section 7.5</a> .   |

## 6.2.19 Device Rev ID (Word 0x1E)

| Bit | Name               | Default in EEPROM less mode | Description                                                                                                                                               |
|-----|--------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | Power Down Enable  | 0b                          | Enable Power down when DEV_OFF_N pin is asserted or PCIe in Dr state. Refer to <a href="#">Section 5.2.4.1</a> for details.                               |
| 14  | LAN 3 iSCSI enable | 0b                          | When set, LAN 3 class code is set to 0x010000 (SCSI)<br>When reset, LAN 3 class code is set to 0x020000 (LAN)<br>Refer to <a href="#">Section 9.4.6</a> . |
| 13  | LAN 2 iSCSI enable | 0b                          | When set, LAN 2 class code is set to 0x010000 (SCSI)<br>When reset, LAN 2 class code is set to 0x020000 (LAN)<br>Refer to <a href="#">Section 9.4.6</a> . |
| 12  | LAN 1 iSCSI enable | 0b                          | When set, LAN 1 class code is set to 0x010000 (SCSI)<br>When reset, LAN 1 class code is set to 0x020000 (LAN)<br>Refer to <a href="#">Section 9.4.6</a> . |

| Bit  | Name                   | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                 |
|------|------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11   | LAN 0 iSCSI enable     | 0b                          | When set, LAN 0 class code is set to 0x010000 (SCSI)<br>When reset, LAN 0 class code is set to 0x020000 (LAN)<br>Refer to <a href="#">Section 9.4.6</a> .                                                                                                                                   |
| 10:8 | AER Capability Version | 0x2                         | AER Capability Version Number<br>PCIe AER extended capability version number.<br>Refer to <a href="#">Section 9.6.1.1</a> .<br><b>Note:</b> Only the 3 LSB bits of the field are configured.                                                                                                |
| 7:0  | DEVREVID               | 0x0                         | Device Revision ID<br>This field is loaded to <i>MREVID.EEPROM_RevID</i> ( <a href="#">Section 8.6.10</a> )<br>The actual device revision ID is the EEPROM value XORed with the hardware default of Rev ID. For I350 A1, the default value is one. Refer to <a href="#">Section 9.4.5</a> . |

## 6.2.20 LED 0,2 Configuration Defaults (LAN Base Address + Offset 0x1F)

These EEPROM words specify the hardware defaults for the LEDCTL register fields controlling the LED0 (LINK\_UP) and LED2 (LINK\_100) output behaviors. Words control LEDs behavior of LAN 0, LAN 1, LAN 2 and LAN 3 ports.

| Bit   | Name              | Default in EEPROM less mode | Description                                                                                                                                                                                                                                              |
|-------|-------------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15    | LED2 Blink        | 0b                          | Initial value of <i>LED2_BLINK</i> field.<br>0b = Non-blinking.<br>Refer to <a href="#">Section 8.2.9</a> and <a href="#">Section 7.5</a> .                                                                                                              |
| 14    | LED2 Invert       | 0b                          | Initial value of <i>LED2_IVRT</i> field.<br>0b = Active-low output.<br>Refer to <a href="#">Section 8.2.9</a> and <a href="#">Section 7.5</a> .                                                                                                          |
| 13:12 | Reserved          | 0x0                         | Reserved                                                                                                                                                                                                                                                 |
| 11:8  | LED2 Mode         | 0110b                       | Initial value of the <i>LED2_MODE</i> field specifying what event/state/pattern is displayed on LED2 (LINK_100) output. A value of 0110b (0x6) indicates 100 Mb/s operation.<br>Refer to <a href="#">Section 8.2.9</a> and <a href="#">Section 7.5</a> . |
| 7     | LED0 Blink        | 0b                          | Initial value of <i>LED0_BLINK</i> field.<br>0b = Non-blinking.<br>Refer to <a href="#">Section 8.2.9</a> and <a href="#">Section 7.5</a> .                                                                                                              |

| 5     | Global Blink Mode | 0b                          | Global Blink Mode<br>0b = Blink at 200 ms on and 200ms off.<br>1b = Blink at 83 ms on and 83 ms off.<br>Refer to <a href="#">Section 8.2.9</a> and <a href="#">Section 7.5</a> .                                                                         |
| 4     | Reserved          | 0b                          | Reserved. Set to 0b.                                                                                                                                                                                                                                     |
| 3:0   | LED0 Mode         | 0010b                       | Initial value of the <i>LED0_MODE</i> field specifying what event/state/pattern is displayed on LED0 (LINK_UP) output. A value of 0010b (0x2) indicates the LINK_UP state.<br>Refer to <a href="#">Section 8.2.9</a> and <a href="#">Section 7.5</a> .   |

## 6.2.21 Software Defined Pins Control (LAN Base Address + Offset 0x20)

These words at offset 0x20 from start of relevant EEPROM section are used to configure initial settings of software defined pins (SDPs) for LAN 0, LAN 1, LAN 2 and LAN 3.

| Bit | Name                   | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| 4   | Giga Disable            | 0b                          | When set, GbE operation is disabled. A usage example for this bit is to disable GbE operation if system power limits are exceeded (refer to <a href="#">Section 3.7.8.5.4</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3   | Disable 1000 in non-D0a | 1b                          | Disables 1000 Mb/s operation in non-D0a states (refer to <a href="#">Section 3.7.8.5.4</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 2   | D3COLD_WAKEUP_ADVEN     | 1b                          | Controls reporting of D3 Cold wake-up support in the <i>Power Management Capabilities (PMC)</i> configuration register (refer to <a href="#">Section 9.5.1.3</a> ).<br>In addition bit is loaded to <i>CTRL.ADV3WUC</i> (refer to <a href="#">Section 8.2.1</a> ).<br>When set, D3Cold wake up capability is advertised based on whether AUX_PWR pin is connected to 3.3V to advertise presence of auxiliary power (yes if AUX_PWR is indicated, no otherwise). When 0b, however, D3Cold wake up capability is not advertised even if AUX_PWR presence is indicated.<br>If full 1Gb/sec. operation in D3 state is desired but the system's power requirements in this mode would exceed the D3Cold Wake up-Enabled specification limit (375mA at 3.3V), this bit can be used to prevent the capability from being advertised to the system. |
| 1   | SDPVAL[1]               | 0b                          | SDP1 Pin – Initial Output Value<br>This bit configures the initial power-on value output on SDP1 (when configured as an output) by configuring the initial hardware value of the <i>SDP1_DATA</i> bit in the Device Control ( <i>CTRL</i> ) register after power up. <a href="#">See section 8.2.1</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 0   | SDPVAL[0]               | 0b                          | SDP0 Pin – Initial Output Value<br>This bit configures the initial power-on value output on SDP0 (when configured as an output) by configuring the initial hardware value of the <i>SDP0_DATA</i> bit in the Device Control ( <i>CTRL</i> ) register after power up. <a href="#">See section 8.2.1</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## 6.2.22 Functions Control (Word 0x21)

| Bit | Name                           | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----|--------------------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | NC-SI Clock Pad Drive Strength | 0b                          | Defines the drive strength of the NCSI_CLK_OUT pad. If set, the driving strength is stronger. Refer to <a href="#">Section 11.6.1.4</a> for details.                                                                                                                                                                                                                                                                                                                                                                              |
| 14  | NC-SI Data Pad Drive Strength  | 0b                          | Defines the drive strength of the NCSI_CRS_DV, NCSI_RXD and NCSI_ARB_OUT pads. If set, the driving strength is stronger. Refer to <a href="#">Section 11.6.1.4</a> for details.                                                                                                                                                                                                                                                                                                                                                   |
| 13  | NC-SI Output Clock Disable     | 0b                          | If set, the clock source is external. In this case, the NCSI_CLK_OUT pad is kept stable at zero and the NCSI_CLK_IN pad is used as an input source of the clock.<br>If cleared, the I350 outputs the NC-SI clock through the NCSI_CLK_OUT pad. The NCSI_CLK_IN pad is still used as a NC-SI clock input.<br>If NC-SI is not used, then this bit should be set.<br>If this bit is cleared, the Device Power Down Enable bit in word 0x1E (bit 15) should not be set.                                                               |
| 12  | LAN Function Sel               | 0b                          | LAN Function Select<br>When all LAN ports are enabled and <i>LAN Function Sel</i> = 0b, LAN 0 is routed to PCI Function 0, LAN 1 is routed to PCI Function 1, etc. If LAN Function Sel = 1b, LAN 0 is routed to PCI Function 3, LAN 1 is routed to PCI Function 2, etc. This bit is Mapped to <i>FACTPS[30]</i> bit (refer to <a href="#">Section 8.6.9</a> ).<br>Refer to <a href="#">Section 4.4.2</a> for a detailed function to port mapping as a function of the <i>LAN Function Select</i> bit and the LAN Disable signals. |
| 11  | NC-SI ARB Enable               | 0b                          | NCSI Hardware Arbitration enable<br>0b - NCSI_ARB_IN and NCSI_ARB_OUT pads are not used. NCSI_ARB_IN is pulled up internally to provide stable input.<br>1b - NCSI_ARB_IN and NCSI_ARB_OUT pads are used.                                                                                                                                                                                                                                                                                                                         |

| Bit | Name            | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                                                                                    |
|-----|-----------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10  | BAR32           | 1b                          | Bit (loaded to the <i>BARCTRL</i> register) preserves the legacy 32 bit BAR mode when BAR32 is set. When cleared to 0b 64 bit BAR addressing mode is selected.<br>Note: If <i>PREFBAR</i> is set the <i>BAR32</i> bit should always be 0 (64 bit BAR addressing mode).<br>Refer to <a href="#">Section 9.4.11</a> .                                                            |
| 9   | PREFBAR         | 0b                          | 0b - BARs are marked as non prefetchable<br>1b - BARs are marked as prefetchable<br>Refer to <a href="#">Section 9.4.11</a> .<br><b>Notes:</b><br>1. This bit should be set only on systems that do not generate prefetchable cycles. This bit is loaded from the <i>PREFBAR</i> bit in the EEPROM.<br>2. If <i>PREFBAR</i> bit is set then the <i>BAR32</i> bit should be 0b. |
| 8   | drop_os2bmc     | 1b                          | 0b - Do not drop OS2BMC packets when management buffer is not available.<br>1b - Drop OS2BMC packets when management buffer is not available.<br><b>Note:</b> Clearing bit will avoid loss of OS2BMC traffic but may cause head of line blocking on traffic to network.                                                                                                        |
| 7:3 | Reserved        | 01000b                      | Reserved                                                                                                                                                                                                                                                                                                                                                                       |
| 2   | drop_bmc2os     | 1b                          | 0b - Do not drop BMC2OS packets when no RX descriptors are available.<br>1b - Drop BMC2OS packets when no RX descriptors are available.                                                                                                                                                                                                                                        |
| 1   | Deep DEV_OFF    | 0b                          | Deep DEV_OFF_N power saving mode<br>When bit is set to 1b power saving when DEV_OFF_N is asserted is increased.<br><b>Note:</b> For bit to take effect the <i>Power Down Enable</i> bit in the <a href="#">Section 6.2.19, Device Rev ID (Word 0x1E)</a> EEPROM word should be set.                                                                                            |
| 0   | NC-SI Slew Rate | 1b                          | Defines the slew rate of the <i>NCSI_CLK_OUT</i> , <i>NCSI_CRS_DV</i> , <i>NCSI_RXD</i> and <i>NCSI_ARB_OUT</i> pads. If set, the slew rate is high.                                                                                                                                                                                                                           |

## 6.2.23 LAN Power Consumption (Word 0x22)

| Bit  | Name                    | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|-------------------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8 | LAN D0 Power            | 0x0                         | The value in this field is reflected in the PCI Power Management Data Register of the LAN functions for D0 power consumption and dissipation ( <i>Data_Select</i> = 0 or 4). Power is defined in 100mW units. The power includes also the external logic required for the LAN function. Refer to <a href="#">Section 9.5.1.4</a> .                                                                                      |
| 7:5  | Function 0 Common Power | 0x0                         | The value in this field is reflected in the PCI Power Management Data register of function 0 when the <i>Data_Select</i> field is set to 8 (common function). The MSBs in the data register that reflects the power values are padded with zeros. Refer to <a href="#">Section 9.5.1.4</a> .                                                                                                                            |
| 4:0  | LAN D3 Power            | 0x0                         | The value in this field is reflected in the PCI Power Management Data register of the LAN functions for D3 power consumption and dissipation ( <i>Data_Select</i> = 3 or 7). Power is defined in 100 mW units. The power also includes the external logic required for the LAN function. The MSBs in the data register that reflects the power values are padded with zeros. Refer to <a href="#">Section 9.5.1.4</a> . |

## 6.2.24 Initialization Control 3 (LAN Base Address + Offset 0x24)

These words control general initialization values of LAN 0, LAN 1, LAN 2 and LAN 3 ports.

| Bit   | Name                 | Default in EEPROM less mode                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |       |          |                                  |     |      |   |     |      |   |     |      |   |     |      |   |

|-----|---------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5:4 | Link Mode           | 00b                         | Initial value of <i>Link Mode</i> bits of the Extended Device Control ( <i>CTRL_EXT.LINK_MODE</i> ) register, specifying which link interface and protocol is used by the MAC.<br>00b = MAC operates with internal copper PHY (10/100/1000Base-T).<br>01b = MAC and SerDes I/F operate in 1000BASE-KX mode.<br>10b = MAC and SerDes operate in SGMII mode.<br>11b = MAC and SerDes I/F operate in SerDes (1000BASE-BX) mode.<br><a href="#">Section 8.2.3</a> . |
| 3   | Com_MDIO            | 0b                          | When interfacing an external SGMII PHY or SerDes, bit defines if MDIO access is routed to a shared MDIO port on LAN 0, to support multi port external PHYs or to the dedicated per function MDIO port.<br>0b - MDIO access routed to the LAN port's MDIO interface.<br>1b - MDIO accesses on this LAN port routed to LAN port 0 MDIO interface.<br>Used to set the default value of <i>MDICNFG.Com_MDIO</i> bit (refer to <a href="#">Section 8.2.5</a> ).      |
| 2   | External MDIO       | 0b                          | When set PHY management interface is via external MDIO interface. Loaded to <i>MDICNFG.Destination</i> (refer to <a href="#">Section 8.2.5</a> ).                                                                                                                                                                                                                                                                                                               |
| 1   | EXT_VLAN            | 0b                          | Sets the default for <i>CTRL_EXT[26]</i> bit. Indicates that additional VLAN is expected in this system (refer to <a href="#">Section 8.2.3</a> ).                                                                                                                                                                                                                                                                                                              |
| 0   | Keep_PHY_Link_Up_En | 0b                          | Enables <i>No PHY Reset</i> when the Baseboard Management Controller (BMC) indicates that the PHY should be kept on. When asserted, this bit prevents the PHY reset signal and the power changes reflected to the PHY according to the <i>MANC.Keep_PHY_Link_Up</i> value.<br>Note: This EEPROM bit should be set to the same value for all LAN ports.                                                                                                          |

## 6.2.25 I/O Virtualization (IOV) Control (Word 0x25)

This word controls IOV functionality.

| Bit  | Name                 | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                                                                                                            |
|------|----------------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15   | drop_vm_lpbk         | 0b                          | 0b - Do not drop VM to VM loopback packets when loopback buffer is not available.<br>1b - Drop VM to VM loopback packets when loopback buffer is not available.<br><br><b>Notes:</b><br>1. Clearing bit will avoid loss of VM to VM traffic but may cause head of line blocking on traffic to network.<br>2. When RX descriptor is not available for loop backed packet, drop operation always occurs. |
| 14:9 | Reserved             | 0x0                         | Reserved - must be zero                                                                                                                                                                                                                                                                                                                                                                                |
| 8    | ARI Enabled          | 1b                          | 0b = ARI capability structure not exposed as part of the capabilities link list.<br>1b = ARI capability structure exposed as part of the capabilities link list.                                                                                                                                                                                                                                       |
| 7:5  | Max VFs              | 0x7                         | Defines the value of MaxVF exposed in the IOV structure. Valid values are 0-7. The value exposed in the PCIe configuration space is the value of this field + one.                                                                                                                                                                                                                                     |
| 4:3  | MSI-X table          | 0x2                         | Defines the size of the VF function MSI-X table to request.<br>Valid values are 0-2 (refer to <a href="#">Section 9.7.2.1</a> ).                                                                                                                                                                                                                                                                       |
| 2    | 64-bit Advertisement | 1b                          | 0b = VF BARs advertise 32-bit size.<br>1b = VF BARs advertise 64-bit size.<br><b>Note:</b> The <i>Prefetchable</i> bit should be set in the <i>I/O Virtualization (IOV) Control</i> EEPROM word when the bit is set to 1b.                                                                                                                                                                             |

| Bit | Name         | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                |
|-----|--------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Prefetchable | 0b                          | 0b = IOV memory BARS (0 and 3) are declared as non prefetchable.<br>1b = IOV memory BARS (0 and 3) are declared as prefetchable.<br><b>Note:</b> The 64-bit Advertisement bit should be set in the I/O Virtualization (IOV) Control EEPROM word when the bit is set to 1b. |
| 0   | IOV Enabled  | 1b                          | 0b = IOV capability structure not exposed as part of the capabilities link list.<br>1b = IOV capability structure exposed as part of the capabilities link list.                                                                                                           |

## 6.2.26 IOV Device ID (Word 0x26)

| Bit  | Name    | Default in EEPROM less mode | Description                                                                                                                           |
|------|---------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | VDev ID | 0x1520                      | Virtual function device ID.<br>Loaded to PCIe SR-IOV VF device ID configuration register (refer to <a href="#">Section 9.6.4.7</a> ). |

## 6.2.27 PCIe Control 2 (Word 0x28)

This word is used to configure initial settings for the PCIe default functionality.

| Bits  | Name                  | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|-------|-----------------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:13 | Reserved              |                             | Reserved                                                                                                                                                                                                                                                                                                                                                                                                   |
| 12    | ECRC Check            | 1b                          | Loaded into the ECRC Check Capable bit of the PCIe configuration registers<br>0b - Function is not capable of checking ECRC<br>1b - Function is capable of checking ECRC                                                                                                                                                                                                                                   |
| 11    | ECRC Generation       | 1b                          | Loaded into the ECRC Generation Capable bit of the PCIe configuration registers.<br>0b - Function is not capable of generating ECRC<br>1b - Function is capable of generating ECRC                                                                                                                                                                                                                         |
| 10    | FLR capability enable | 1b                          | FLR capability Enable bit is loaded to "PCIe configuration registers" -> "Device Capabilities".                                                                                                                                                                                                                                                                                                            |
| 9:6   | FLR delay             | 0x1                         | Delay in microseconds from D0 to D3 move till reset assertion.                                                                                                                                                                                                                                                                                                                                             |
| 5     | FLR delay disable     | 0b                          | FLR delay disable.<br>0 - Add delay to FLR assertion.<br>1 - Do not add delay to FLR assertion.                                                                                                                                                                                                                                                                                                            |
| 4     | Reserved              |                             | Reserved                                                                                                                                                                                                                                                                                                                                                                                                   |
| 3:1   | Flash Size            | 000b                        | Indicates Flash size according to the following equation:<br>Size = 64 KB * 2 <sup>*(Flash Size field)</sup> . From 64 KB up to 8 MB in powers of 2.<br>The Flash size impacts the requested memory space for the Flash and expansion ROM BARs in PCIe configuration space.<br>Note: When CSR_Size and Flash_size fields in the EEPROM are set to 0, Flash BAR in the PCI configuration space is disabled. |
| 0     | CSR_Size              | 0b                          | The CSR_Size and FLASH_Size fields define the usable FLASH size and CSR mapping window size as shown in BARCTRL register description.<br>Note: When CSR_Size and Flash Size fields in the EEPROM are set to 0, Flash BAR in the PCI configuration space is disabled.                                                                                                                                       |

## 6.2.28 PCIe Control 3 (Word 0x29)

This word is used for programming PCIe functionality and function disable control.

| Bits | Name                        | Default in EEPROM less mode | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|------|-----------------------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15   | en_pin_pcie_func_dis        | 0b                          | When set to 1b enables disabling the relevant PCIe function by driving the relevant SDPx_1 pin (SDP0_1, SDP1_1, SDP2_1 or SDP3_1) to "0" (refer to <a href="#">Section 4.4.4</a> ).<br><b>Note:</b> The SDPx_1 pins on all 4 ports are sampled on Power-up and during PCIe reset.                                                                                                                    |
| 14   | LAN_DIS_POL                 | 0b                          | Defines active polarity (active high or active low) of the LANx_DIS_N pins.<br>0b - LANx_DIS_N pins are active low (LAN port disabled when 0 driven during PCIe reset).<br>1b - LANx_DIS_N pins are active high (LAN port disabled when 1 driven during PCIe reset).<br>Refer to <a href="#">Section 4.4.3</a> and <a href="#">Section 4.4.4</a> for additional information.                         |
| 13   | PCI_DIS_POL                 | 0b                          | Defines active polarity (active high or active low) of the SDPx_1 pins when the en_pin_pcie_func_dis EEPROM bit is set to 1b.<br>0b - SDPx_1 pins are active low (PCIe function disabled when 0 is driven during PCIe reset).<br>1b - SDPx_1 pins are active high (PCIe function disabled when 1 is driven during PCIe reset).<br>Refer to <a href="#">Section 4.4.4</a> for additional information. |

| 1:0  | Reserved                    |                             | Reserved                                                                                                                                                                                                                                                                                                                                                                                             |

## 6.2.29 End of Read-Only (RO) Area (Word 0x2C)

Defines the end of the area in the EEPROM that is RO.

| Bit  | Name      | Description                                                                                                                                                                 |
|------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15   | Reserved  | Reserved                                                                                                                                                                    |
| 14:0 | EORO_area | Defines the end of the area in the EEPROM that is RO. The resolution is one word and can be up to byte address 0xFFFF (0x7FFF words). A value of zero indicates no RO area. |

## 6.2.30 Start of RO Area (Word 0x2D)

Defines the start of the area in the EEPROM that is RO.

| Bit  | Name      | Description                                                                                                                             |
|------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 15   | Reserved  | Reserved                                                                                                                                |
| 14:0 | SORO_area | Defines the start of the area in the EEPROM that is RO. The resolution is one word and can be up to byte address 0xFFFF (0x7FFF words). |

### 6.2.31 Watchdog Configuration (Word 0x2E)

| Bit   | Name             | Default in EEPROM less mode | Description                                                                                                                                                                                                                         |
|-------|------------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15    | Watchdog Enable  | 0b                          | Enable watchdog interrupt. Refer to <a href="#">Section 8.15.1</a> .<br><b>Note:</b> If bit is set to 1b value of EEPROM <i>Watchdog Timeout</i> field should be 2 or higher to avoid immediate generation of a watchdog interrupt. |
| 14:11 | Watchdog Timeout | 0x2                         | Watchdog timeout period (in seconds). Refer to <a href="#">Section 8.15.1</a> .<br>Note: Loaded to 4 LSB bits of <i>WDSTP.WD_Timeout</i> field.                                                                                     |
| 10:0  | Reserved         |                             | Reserved                                                                                                                                                                                                                            |

### 6.2.32 VPD Pointer (Word 0x2F)

This word points to the Vital Product Data (VPD) structure. This structure is available for the NIC vendor to store its own data. A value of 0xFFFF indicates that the structure is not available.

| Bit  | Name       | Description                                                                                                                                                 |
|------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | VPD offset | Offset to VPD structure in words.<br><b>Notes:</b><br>1. A value of 0xFFFF indicates that the structure is not available.<br>2. Value of bit 15 is ignored. |

## 6.3 CSR Auto load Modules

The structures in this section are used to auto load CSRs in some reset events.

**Note:** PHY CSRs can not be programmed using these modules, only through the PHY configuration module ([Section 6.3.13](#)).

### 6.3.1 Software Reset CSR Auto Configuration Pointer (LAN Base Address + Offset 0x17)

Word points to the software Reset CSR auto configuration structures of LAN 0, LAN 1, LAN 2 and LAN3. Sections are loaded during HW auto-load as described in [Section 3.3.1.3](#). If no CSR autoload is required for the specific LAN port, the word must be set to 0xFFFF.

The software Reset CSR Auto Configuration structure format is listed in the following tables.

**Table 6-4 SW Reset CSR Auto Configuration Structure Format**

| Offset      | High Byte[15:8]                                            | Low Byte[7:0] | Section                         |
|-------------|------------------------------------------------------------|---------------|---------------------------------|
| 0x0         | Section Length = $3 * n$ (n – number of CSRs to configure) |               | <a href="#">Section 6.3.2</a>   |
| 0x1         | Block CRC8                                                 |               | <a href="#">Section 6.3.2.1</a> |
| 0x2         | CSR Address                                                |               | <a href="#">Section 6.3.2.2</a> |
| 0x3         | Data LSB                                                   |               | <a href="#">Section 6.3.2.3</a> |
| 0x4         | Data MSB                                                   |               | <a href="#">Section 6.3.2.4</a> |
|             | ...                                                        |               |                                 |
| $3 * n - 1$ | CSR Address                                                |               | <a href="#">Section 6.3.2.2</a> |
| $3 * n$     | Data LSB                                                   |               | <a href="#">Section 6.3.2.3</a> |
| $3 * n + 1$ | Data MSB                                                   |               | <a href="#">Section 6.3.2.4</a> |

## 6.3.2 Software Reset CSR Configuration Section Length - Offset 0x0

The section length word contains the length of the section in words. Note that section length count does not include the section length word and Block CRC8 word.

| Bits | Name           | Default | Description                                                               |
|------|----------------|---------|---------------------------------------------------------------------------|
| 15   | Reserved       |         |                                                                           |
| 14:0 | Section_length |         | Section length in words ( $3 * \text{number of CSRs to be configured}$ ). |

### 6.3.2.1 Block CRC8 (Offset 0x1)

| Bit  | Name     | Description |
|------|----------|-------------|
| 15:8 | Reserved |             |
| 7:0  | CRC8     |             |

### 6.3.2.2 CSR Address - (Offset $3 * n - 1$ ; [n = 1... Section Length])

| Bits | Name     | Default | Description                           |
|------|----------|---------|---------------------------------------|
| 15   | Reserved |         |                                       |
| 14:0 | CSR_ADDR |         | CSR Address in Double Words (4 bytes) |

### 6.3.2.3 CSR Data LSB - (Offset $3*n$ ; [ $n = 1 \dots$ Section Length])

| Bits | Name         | Default | Description  |
|------|--------------|---------|--------------|
| 15:0 | CSR_Data_LSB |         | CSR Data LSB |

### 6.3.2.4 CSR Data MSB - (Offset $3*n + 1$ ; [ $n = 1 \dots$ Section Length])

| Bits | Name         | Default | Description  |
|------|--------------|---------|--------------|
| 15:0 | CSR_Data_MSB |         | CSR Data MSB |

## 6.3.3 PCIe Reset CSR Auto Configuration Pointer (LAN Base Address + Offset 0x23)

This word points to the *PCIe Reset CSR auto configuration* structures of LAN 0, LAN 1, LAN 2 and LAN3 that are read only following power-up or PCIe reset. Sections are loaded during HW auto-load as described in [Section 3.3.1.3](#). If no CSR autoloading is required for the specific LAN port, the word must be set to 0xFFFF.

The *PCIe Reset CSR Auto Configuration* structure format is listed in the following tables.

**Table 6-5 PCIe Reset CSR Auto Configuration Structure Format**

| Offset    | High Byte[15:8]                                             | Low Byte[7:0] | Section                         |
|-----------|-------------------------------------------------------------|---------------|---------------------------------|
| 0x0       | Section Length = $3*n$ ( $n$ - number of CSRs to configure) |               | <a href="#">Section 6.3.3.1</a> |
| 0x1       | Block CRC8                                                  |               | <a href="#">Section 6.3.3.2</a> |
| 0x2       | CSR Address                                                 |               | <a href="#">Section 6.3.3.3</a> |
| 0x3       | Data LSB                                                    |               | <a href="#">Section 6.3.3.4</a> |
| 0x4       | Data MSB                                                    |               | <a href="#">Section 6.3.3.5</a> |
|           | ...                                                         |               |                                 |
| $3*n - 1$ | CSR Address                                                 |               | <a href="#">Section 6.3.4.3</a> |
| $3*n$     | Data LSB                                                    |               | <a href="#">Section 6.3.4.4</a> |
| $3*n + 1$ | Data MSB                                                    |               | <a href="#">Section 6.3.4.5</a> |

### 6.3.3.1 PCIe Reset CSR Configuration Section Length - Offset 0x0

The section length word contains the length of the section in words. Note that section length count does not include the section length word and Block CRC8 word.

| Bits | Name           | Default | Description                                                               |
|------|----------------|---------|---------------------------------------------------------------------------|
| 15   | Reserved       |         |                                                                           |
| 14:0 | Section_length |         | Section length in words ( $3 * \text{number of CSRs to be configured}$ ). |

### 6.3.3.2 Block CRC8 (Offset 0x1)

| Bit  | Name     | Description |
|------|----------|-------------|
| 15:8 | Reserved |             |
| 7:0  | CRC8     |             |

### 6.3.3.3 CSR Address - (Offset 3\*n - 1; [n = 1... Section Length])

| Bits | Name     | Default | Description                           |
|------|----------|---------|---------------------------------------|
| 15   | Reserved |         |                                       |
| 14:0 | CSR_ADDR |         | CSR Address in Double Words (4 bytes) |

### 6.3.3.4 CSR Data LSB - (Offset 3\*n; [n = 1... Section Length])

| Bits | Name         | Default | Description  |
|------|--------------|---------|--------------|
| 15:0 | CSR_Data_LSB |         | CSR Data LSB |

### 6.3.3.5 CSR Data MSB - (Offset 3\*n + 1; [n = 1... Section Length])

| Bits | Name         | Default | Description  |
|------|--------------|---------|--------------|
| 15:0 | CSR_Data_MSB |         | CSR Data MSB |

## 6.3.4 CSR Auto Configuration Power-Up Pointer (LAN Base Address + Offset 0x27)

This word points to the CSR auto configuration Power-Up structures of LAN 0, LAN 1, LAN 2 and LAN3 that are read only following power-up. Sections are loaded during HW auto-load as described in [Section 3.3.1.3](#). If no CSR autoload is required for the specific LAN port, the word must be set to 0xFFFF.

The CSR Auto Configuration Power-Up structure format is listed in the following tables.

**Table 6-6 CSR Auto Configuration Power-Up Structure Format**

| Offset | High Byte[15:8]                                        | Low Byte[7:0] | Section                         |
|--------|--------------------------------------------------------|---------------|---------------------------------|
| 0x0    | Section Length = 3*n (n – number of CSRs to configure) |               | <a href="#">Section 6.3.4.1</a> |
| 0x1    | Block CRC8                                             |               | <a href="#">Section 6.3.4.2</a> |
| 0x2    | CSR Address                                            |               | <a href="#">Section 6.3.4.3</a> |
| 0x3    | Data LSB                                               |               | <a href="#">Section 6.3.4.4</a> |
| 0x4    | Data MSB                                               |               | <a href="#">Section 6.3.4.5</a> |
|        | ...                                                    |               |                                 |

**Table 6-6 CSR Auto Configuration Power-Up Structure Format**

| Offset  | High Byte[15:8] | Low Byte[7:0] | Section         |
|---------|-----------------|---------------|-----------------|
| 3*n - 1 | CSR Address     |               | Section 6.3.4.3 |
| 3*n     | Data LSB        |               | Section 6.3.4.4 |
| 3*n + 1 | Data MSB        |               | Section 6.3.4.5 |

### 6.3.4.1 CSR Configuration Power-Up Section Length - Offset 0x0

The section length word contains the length of the section in words. Note that section length count does not include the section length word and Block CRC8 word.

| Bits | Name           | Default | Description                                                    |
|------|----------------|---------|----------------------------------------------------------------|
| 15   | Reserved       |         |                                                                |
| 14:0 | Section_length |         | Section length in words (3 * number of CSRs to be configured). |

### 6.3.4.2 Block CRC8 (Offset 0x1)

| Bit  | Name     | Description |
|------|----------|-------------|
| 15:8 | Reserved |             |
| 7:0  | CRC8     |             |

### 6.3.4.3 CSR Address - (Offset 3\*n - 1; [n = 1... Section Length])

| Bits | Name     | Default | Description                           |
|------|----------|---------|---------------------------------------|
| 15   | Reserved |         |                                       |
| 14:0 | CSR_ADDR |         | CSR Address in Double Words (4 bytes) |

### 6.3.4.4 CSR Data LSB - (Offset 3\*n; [n = 1... Section Length])

| Bits | Name         | Default | Description  |
|------|--------------|---------|--------------|
| 15:0 | CSR_Data_LSB |         | CSR Data LSB |

### 6.3.4.5 CSR Data MSB - (Offset 3\*n + 1; [n = 1... Section Length])

| Bits | Name         | Default | Description  |
|------|--------------|---------|--------------|
| 15:0 | CSR_Data_MSB |         | CSR Data MSB |

### 6.3.5 PCIe PHY Auto Configuration Pointer (Word 0x10)

This word points to the PCIe PHY auto configuration structure used to configure PCIe PHY related circuitry. Sections are loaded during HW auto-load as described in [Section 3.3.1.3](#).

The PCIe PHY Auto Configuration structure format is listed in the following table.

**Table 6-7 PCIe PHY Auto Configuration Structure format**

| Offset  | High Byte[15:8]                                             | Low Byte[7:0] | Section                         |
|---------|-------------------------------------------------------------|---------------|---------------------------------|
| 0x0     | Section Length = 2*n (n – number of registers to configure) |               | <a href="#">Section 6.3.5.1</a> |
| 0x1     | Block CRC8                                                  |               | <a href="#">Section 6.3.5.3</a> |
| 0x2     | Register Address                                            |               | <a href="#">Section 6.3.5.3</a> |
| 0x3     | Data                                                        |               | <a href="#">Section 6.3.5.4</a> |
|         | ...                                                         |               |                                 |
| 2*n     | Register Address                                            |               | <a href="#">Section 6.3.5.3</a> |
| 2*n + 1 | Data                                                        |               | <a href="#">Section 6.3.5.4</a> |

#### 6.3.5.1 PCIe PHY Configuration Section Length - Offset 0x0

The section length word contains the length of the section in words. Note that section length count does not include the section length word and Block CRC8 word.

| Bits | Name           | Default | Description                                                              |
|------|----------------|---------|--------------------------------------------------------------------------|
| 15   | Reserved       |         |                                                                          |
| 14:0 | Section_length |         | Length in words of register write section (2 * registers to be written). |

#### 6.3.5.2 Block CRC8 (Offset 0x1)

| Bit  | Name     | Description |
|------|----------|-------------|
| 15:8 | Reserved |             |
| 7:0  | CRC8     |             |

#### 6.3.5.3 Register Address - (Offset 2\*n; [n = 1... Number of Registers to be Written])

| Bits | Name     | Default | Description                                  |
|------|----------|---------|----------------------------------------------|
| 15:0 | Reg_ADDR |         | PCIe PHY Register Address in Words (2 bytes) |

#### 6.3.5.4 Register Data - (Offset 2\*n + 1; [n = 1... Number of Registers to be Written])

| Bits | Name     | Default | Description |
|------|----------|---------|-------------|
| 15:0 | Reg_Data |         | CSR Data    |

### 6.3.5.5 Setting Default PCIe Link Width and Link Speed

By default, the I350 PCIe interface is configured to a maximum Link speed of 5.0 Gb/s and Link Width of 4 lanes. Default link width and speed can be modified by programming the Internal *PCIe Link Configuration Register* using the PCIe PHY Configuration data EEPROM Section as described below:

#### 6.3.5.5.1 PCIe Link Configuration Register Address - Offset 0x2

| Bits | Field    | Address | Description                                                 |
|------|----------|---------|-------------------------------------------------------------|
| 15:0 | Reg_ADDR | 0x94    | PCIe Link Configuration Register Address in Words (2 bytes) |

#### 6.3.5.5.2 PCIe Link Configuration Register Data - Offset 0x3

Placing a value of 0x0 in the *PCIe Link Configuration Register Data* EEPROM word configures the I350 PCIe interface to PCIe Gen 2 link rates and a link width of 4.

| Bits | Field              | Default in EEPROMless mode | Description                                                                            |
|------|--------------------|----------------------------|----------------------------------------------------------------------------------------|
| 15:9 | Reserved           | 0x0                        | Reserved.<br>Value should be 0.                                                        |
| 8    | Disable PCIe Gen 2 | 0b                         | 1b - 2.5 Gb/s Link speed supported<br>0b - 5.0 Gb/s and 2.5 GT/s Link speeds supported |
| 7:4  | Reserved           | 0x0                        | Reserved.<br>Value should be 0.                                                        |
| 3    | Disable Lane 3     | 0b                         | 0b - Lane 3 enabled<br>1b - Lane 3 disabled                                            |
| 2    | Disable Lane 2     | 0b                         | 0b - Lane 2 enabled<br>1b - Lane 2 disabled                                            |
| 1    | Disable Lane 1     | 0b                         | 0b - Lane 1 enabled<br>1b - Lane 1 disabled                                            |
| 0    | Disable Lane 0     | 0b                         | 0b - Lane 0 enabled<br>1b - Lane 0 disabled                                            |

#### 6.3.5.5.3 PCIe Link Power Down Register Address - Offset 0x4

| Bits | Field    | Address | Description                                                 |
|------|----------|---------|-------------------------------------------------------------|
| 15:0 | Reg_ADDR | 0x96    | PCIe Link Configuration Register Address in Words (2 bytes) |

#### 6.3.5.5.4 PCIe Link Power Down Register Data - Offset 0x5

| Bits  | Field                | Default in EEPROMless mode | Description                                                                                                                                                 |
|-------|----------------------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:12 | Reserved             | 0x0                        | Reserved.<br>Value should be 0.                                                                                                                             |
| 11:8  | Latency_To_Enter_L0s | 0x3                        | Sets Latency in $\mu$ s between PCIe Idle detection and entry to L0s<br><b>Note:</b> PCIe specification defines that the value should not exceed 7 $\mu$ s. |
| 7:6   | Reserved             | 0x0                        | Reserved.<br>Value should be 0.                                                                                                                             |

| Bits | Field               | Default in EEPROMless mode | Description                                                   |
|------|---------------------|----------------------------|---------------------------------------------------------------|
| 5:0  | Latency_To_Enter_L1 | 0x1F                       | Sets Latency in $\mu$ s between entry to L0s and entry to L1. |

### 6.3.6 Management Pass Through LAN Configuration Pointer (LAN Base Address + Offset 0x11)

The Management Pass Through LAN Configuration Pointer (LAN Base Address + Offset 0x11) points to the start (offset 0x0) of this type of structure, to configure manageability filters. If pointer is 0xFFFF then no structure exists. Structure is loaded during HW EEPROM auto-load as described in [Section 3.3.1.3](#).

| Bit  | Name    | Description                                                                                                                                                                                              |
|------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | Pointer | Pointer to the PT LAN Configuration Structure. Refer to for details of the structure.<br><b>Note:</b> Placing a value of 0xFFFF for a pointer indicates that the structure is not present in the EEPROM. |

#### 6.3.6.1 PT LAN Configuration Structure

The Management PT LAN Configuration Structure format is listed in the following tables.

**Table 6-8 Management PT LAN Configuration Structure Format**

| Offset    | High Byte[15:8]                                             | Low Byte[7:0] | Section                         |
|-----------|-------------------------------------------------------------|---------------|---------------------------------|
| 0x0       | Section Length = $3*n$ ( $n$ – number of CSRs to configure) |               | <a href="#">Section 6.3.6.2</a> |
| 0x1       | Block CRC8                                                  |               | <a href="#">Section 6.3.6.3</a> |
| 0x2       | CSR Address                                                 |               | <a href="#">Section 6.3.6.4</a> |
| 0x3       | Data LSB                                                    |               | <a href="#">Section 6.3.6.5</a> |
| 0x4       | Data MSB                                                    |               | <a href="#">Section 6.3.6.6</a> |
|           | ...                                                         |               |                                 |
| $3*n - 1$ | CSR Address                                                 |               | <a href="#">Section 6.3.6.4</a> |
| $3*n$     | Data LSB                                                    |               | <a href="#">Section 6.3.6.5</a> |
| $3*n + 1$ | Data MSB                                                    |               | <a href="#">Section 6.3.6.6</a> |

#### 6.3.6.2 Management PT LAN Configuration Structure Section Length - Offset 0x0

The section length word contains the length of the section in words. Note that section length count does not include the section length word and Block CRC8 word.

| Bits | Name           | Default | Description              |
|------|----------------|---------|--------------------------|
| 15   | Reserved       |         |                          |
| 14:0 | Section_length |         | Section length in words. |

### 6.3.6.3 Block CRC8 (Offset 0x1)

| Bit  | Name     | Description |
|------|----------|-------------|
| 15:8 | Reserved |             |
| 7:0  | CRC8     |             |

### 6.3.6.4 CSR Address - (Offset 2\*n; [n = 1... Section Length])

| Bits | Name     | Default | Description                           |
|------|----------|---------|---------------------------------------|
| 15   | Reserved |         |                                       |
| 14:0 | CSR_ADDR |         | CSR Address in Double Words (4 bytes) |

### 6.3.6.5 CSR Data LSB - (Offset 0x1 + 2\*n; [n = 1... Section Length])

| Bits | Name         | Default | Description  |
|------|--------------|---------|--------------|
| 15:0 | CSR_Data_LSB |         | CSR Data LSB |

### 6.3.6.6 CSR Data MSB - (Offset 0x2 + 2\*n; [n = 1... Section Length])

| Bits | Name         | Default | Description  |
|------|--------------|---------|--------------|
| 15:0 | CSR_Data_MSB |         | CSR Data MSB |

### 6.3.6.7 Manageability Filters

Following table lists registers that can be programmed via the Management PT LAN Configuration structure.

| Name     | Description                                                                                                          | Section                         |
|----------|----------------------------------------------------------------------------------------------------------------------|---------------------------------|
| MAVTV    | Management VLAN TAG Value                                                                                            | <a href="#">Section 8.21.1</a>  |
| MFUTP    | Management Flex UDP/TCP Ports                                                                                        | <a href="#">Section 8.21.2</a>  |
| METF     | Management Ethernet Type Filters                                                                                     | <a href="#">Section 8.21.3</a>  |
| MNGONLY  | Management Only Traffic Register                                                                                     | <a href="#">Section 8.21.5</a>  |
| MDEF     | Manageability Decision Filters                                                                                       | <a href="#">Section 8.21.6</a>  |
| MDEF_EXT | Manageability Decision Filters Extension                                                                             | <a href="#">Section 8.21.7</a>  |
| MIPAF    | Manageability IP Address Filter registers (IPv4 or IPV6)<br>Note: Can be used to filter IPV4 Address of ARP packets. | <a href="#">Section 8.21.8</a>  |
| MMAL     | Manageability MAC Address Low Registers                                                                              | <a href="#">Section 8.21.9</a>  |
| MMAH     | Manageability MAC Address High Registers                                                                             | <a href="#">Section 8.21.10</a> |
| FTFT     | Flexible TCO Filter Table registers                                                                                  | <a href="#">Section 8.21.11</a> |

## 6.3.7 Common Firmware Parameters – (Global MNG Offset 0x3)

### 6.3.7.1 Section Header — Offset 0x0

| Bits | Name         | Default | Description            | Reserved |
|------|--------------|---------|------------------------|----------|
| 15:8 | Block CRC8   |         |                        |          |
| 7:0  | Block Length | 0x3     | Block length in words. |          |

### 6.3.7.2 Common Firmware Parameters 1 - Offset 0x1

| Bits  | Name                           | Default | Description                                                                                                                                                                | Reserved |
|-------|--------------------------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15    | Enable Firmware Reset          |         | 0b = Firmware reset via HICR is disabled.<br>1b = Firmware reset via HICR is enabled.                                                                                      |          |
| 14:13 | Redirection Sideband Interface |         | 00b = SMBus.<br>01b = NC-SI.<br>10b = MCTP.<br>11b = Reserved.                                                                                                             |          |
| 12    | Restore MAC Address            |         | 0b = Do not restore MAC address at power on.<br>1b = Restore MAC address at power on.                                                                                      |          |
| 11    | Reserved                       | 1b      | Reserved                                                                                                                                                                   |          |
| 10:8  | Manageability Mode             |         | 0x0 = None.<br>0x1 = Reserved.<br>0x2 = Pass Through (PT) mode.<br>0x7:0x3 = Reserved.                                                                                     |          |
| 7     | Serdes Power down - port 3     | 1b      | When set, enables the SerDes of port 3 to enter a low power state when the function is in Dr state. Refer to <a href="#">Chapter 5</a> and <a href="#">Section 8.2.3</a> . |          |
| 6     | Serdes Power down - port 2     | 1b      | When set, enables the SerDes of port 2 to enter a low power state when the function is in Dr state. Refer to <a href="#">Chapter 5</a> and <a href="#">Section 8.2.3</a> . |          |
| 5     | LAN1 Force TCO Reset Disable   | 1b      | 0b = Enable Force TCO reset on LAN1.<br>1b = Disable Force TCO reset on LAN1.                                                                                              |          |
| 4     | LAN0 Force TCO Reset Disable   | 1b      | 0b = Enable Force TCO reset on LAN0.<br>1b = Disable Force TCO reset on LAN0.                                                                                              |          |
| 3     | Proxying Capable               | 1b      | 0b = Disable Protocol Offload.<br>1b = Enable Protocol Offload.                                                                                                            |          |
| 2     | OS2BMC Capable                 |         | 0b = Disable.<br>1b = Enable.                                                                                                                                              |          |
| 1     | Serdes Power down - port 1     | 1b      | When set, enables the SerDes of port 1 to enter a low power state when the function is in Dr state. Refer to <a href="#">Chapter 5</a> and <a href="#">Section 8.2.3</a> . |          |
| 0     | Serdes Power down - port 0     | 1b      | When set, enables the SerDes of port 0 to enter a low power state when the function is in Dr state. Refer to <a href="#">Chapter 5</a> and <a href="#">Section 8.2.3</a> . |          |

### 6.3.7.3 Common Firmware Parameters 2 – Offset 0x2

| Bits | Name                                   | Default | Description                                                                                                                                                                                                                                     | Reserved |
|------|----------------------------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15   | Reserved                               | 1b      | Reserved.                                                                                                                                                                                                                                       |          |
| 14   | Reserved                               | 1b      | Reserved.                                                                                                                                                                                                                                       |          |
| 13   | Reserved                               | 1b      | Reserved.                                                                                                                                                                                                                                       |          |
| 12   | Reserved                               | 1b      | Reserved.                                                                                                                                                                                                                                       |          |
| 11   | Multi-Drop NC-SI                       | 1b      | Multi-Drop NC-SI topology.<br>0b - Point-to-point<br>1b - Multi-drop (default)<br>When bit is set the NCSI CRS_DV and NCSI_RXD[1:0] pins are High-Z following power-up, otherwise the pins are driven.                                          |          |
| 10   | PARITY_ERR_RST_EN                      | 1b      | When set enables reset of Management logic and generation of internal Firmware reset as a result of Parity Error detected in Management memories.                                                                                               |          |
| 9    | Enable All Phys in D3                  | 0b      | 0b - Only ports activated for BMC activity will stay active in D3:<br>In NCSI mode – according to enable channel command to the specific port.<br>In SMBUS mode – according to EEPROM port enable bit.<br>1b - All PHYs will stay active in D3. |          |
| 8    | Restore<br>KEEP_PHY_LINK_UP<br>Disable | 1b      | 0b = Restore the KEEP_PHY_LINK_UP bit in the MANC CSR according to the value maintained in firmware.<br>1b = Legacy behavior (KEEP_PHY_LINK_UP is cleared by MAIN_PWR_OK and is not restored by firmware.)                                      |          |

| 4    | LAN2 Force TCO Reset<br>Disable        | 1b      | 0b = Enable Force TCO reset on LAN2.<br>1b = Disable Force TCO reset on LAN2.                                                                                                                                                                   |          |
| 3    | LAN3_FTCO_ISOL_DIS                     | 1b      | LAN3 force TCO Isolate disable (1b disable; 0b enable).                                                                                                                                                                                         |          |
| 2    | LAN2_FTCO_ISOL_DIS                     | 1b      | LAN2 force TCO Isolate disable (1b disable; 0b enable).                                                                                                                                                                                         |          |
| 1    | LAN1_FTCO_ISOL_DIS                     | 1b      | LAN1 force TCO Isolate disable (1b disable; 0b enable).                                                                                                                                                                                         |          |
| 0    | LAN0_FTCO_ISOL_DIS                     | 1b      | LAN0 force TCO Isolate disable (1b disable; 0b enable).                                                                                                                                                                                         |          |

### 6.3.8 Pass Through LAN 0...3 Configuration Modules (Global MNG Offsets 0x05, 0x08, 0x0D, 0x0E)

The following sections describe pointers and structures dedicated to pass-through mode for LAN0, LAN1, LAN2 and LAN3.

- LAN0 structure is pointed by the Firmware Module pointer at offset 0x5.
- LAN1 structure is pointed by the Firmware Module pointer at offset 0x8.
- LAN2 structure is pointed by the Firmware Module pointer at offset 0xD.
- LAN3 structure is pointed by the Firmware Module pointer at offset 0xE.

**Note:** If there's a conflict between the definition in this EEPROM structure and the EEPROM setting in the *PT LAN Configuration Structure* (refer to [Section 6.3.6.1](#)) then the values defined in this structure take precedence.

### 6.3.8.1 Section Header — Offset 0x0

| Bits | Name         | Default | Description            | Reserved |
|------|--------------|---------|------------------------|----------|
| 15:8 | Block CRC8   |         |                        |          |
| 7:0  | Block Length |         | Block length in words. |          |

### 6.3.8.2 LAN 0/1/2/3 IPv4 Address 0 LSB; (MIPAF12 LSB) — Offset 0x01

This value will be stored in the *MIPAF[12]* register (0x58E0). Refer to [Section 8.21.8](#) for a description of this register.

| Bits | Name                      | Default | Description                        | Reserved |
|------|---------------------------|---------|------------------------------------|----------|
| 15:8 | LAN IPv4 Address 0 Byte 1 |         | LAN 0/1/2/3 IPv4 Address 0, Byte 1 |          |
| 7:0  | LAN IPv4 Address 0 Byte 0 |         | LAN 0/1/2/3 IPv4 Address 0, Byte 0 |          |

### 6.3.8.3 LAN 0/1/2/3 IPv4 Address 0 MSB; (MIPAF12 MSB) — Offset 0x02

This value will be stored in the *MIPAF[12]* register (0x58E0). Refer to [Section 8.21.8](#) for a description of this register.

| Bits | Name                      | Default | Description                        | Reserved |
|------|---------------------------|---------|------------------------------------|----------|
| 15:8 | LAN IPv4 Address 0 Byte 3 |         | LAN 0/1/2/3 IPv4 Address 0, Byte 3 |          |
| 7:0  | LAN IPv4 Address 0 Byte 2 |         | LAN 0/1/2/3 IPv4 Address 0, Byte 2 |          |

### 6.3.8.4 LAN 0/1/2/3 IPv4 Address 1; (MIPAF13) — Offset 0x03-0x04

Same structure as LAN0/1/2/3 IPv4 Address 0.

These values will be stored in the *MIPAF[13]* register (0x58E4). Refer to [Section 8.21.8](#) for a description of this register.

### 6.3.8.5 LAN 0/1/2/3 IPv4 Address 2; (MIPAF14) — Offset 0x05-0x06

Same structure as LAN0/1/2/3 IPv4 Address 0.

These values will be stored in the *MIPAF[14]* register (0x58E8). Refer to [Section 8.21.8](#) for a description of this register.

### 6.3.8.6 LAN 0/1/2/3 IPv4 Address 3; (MIPAF15) — Offset 0x07-0x08

Same structure as LAN0/1/2/3 IPv4 Address 0.

These values will be stored in the *MIPAF[15]* register (0x58EC). Refer to [Section 8.21.8](#) for a description of this register.

### 6.3.8.7 LAN 0/1/2/3 Ethernet MAC Address 0 LSB (MMAL0) — Offset 0x09

This word is loaded by firmware to the 16 LS bits of the *MMAL[0]* register. Refer to [Section 8.21.9](#) for a description of the register.

| Bits | Name | Default | Description                                | Reserved |
|------|------|---------|--------------------------------------------|----------|
| 15:8 |      |         | LAN 0/1/2/3 Ethernet MAC Address 0, Byte 1 |          |
| 7:0  |      |         | LAN 0/1/2/3 Ethernet MAC Address 0, Byte 0 |          |

### 6.3.8.8 LAN 0/1/2/3 Ethernet MAC Address 0 MID; (MMAL0) — Offset 0x0A

This word is loaded by firmware to the 16 MS bits of the *MMAL[0]* register.

| Bits | Name | Default | Description                                | Reserved |
|------|------|---------|--------------------------------------------|----------|
| 15:8 |      |         | LAN 0/1/2/3 Ethernet MAC Address 0, Byte 3 |          |
| 7:0  |      |         | LAN 0/1/2/3 Ethernet MAC Address 0, Byte 2 |          |

### 6.3.8.9 LAN 0/1/2/3 Ethernet MAC Address 0 MSB; (MMAH0) — Offset 0x0B

This word is loaded by firmware to the *MMAH[0]* register.

| Bits | Name | Default | Description                                | Reserved |
|------|------|---------|--------------------------------------------|----------|
| 15:8 |      |         | LAN 0/1/2/3 Ethernet MAC Address 0, Byte 5 |          |
| 7:0  |      |         | LAN 0/1/2/3 Ethernet MAC Address 0, Byte 4 |          |

### 6.3.8.10 LAN 0/1/2/3 Ethernet MAC Address 1; (MMAL/H1) — Offset 0x0C-0x0E

Same structure as LAN0 Ethernet MAC Address 0. Loaded to *MMAL[1]* and *MMAH[1]* registers.

### 6.3.8.11 LAN 0/1/2/3 Ethernet MAC Address 2; (MMAL/H2) — Offset 0x0F-0x11

Same structure as LAN0 Ethernet MAC Address 0. Loaded to *MMAL*[2] and *MMAH*[2] registers.

### 6.3.8.12 LAN 0/1/2/3 Ethernet MAC Address 3; (MMAL/H3) — Offset 0x12-0x14

Same structure as LAN0 Ethernet MAC Address 0. Loaded to *MMAL*[3] and *MMAH*[3] registers.

### 6.3.8.13 LAN 0/1/2/3 UDP/TCP Flexible Filter Ports 0 — 7; (MFUTP Registers) — Offset 0x15 - 0x1C

The words depicted in [Table 6-9](#) are loaded by Firmware to the *MFUTP* registers. Refer to [Section 8.21.2](#) for a description of the register.

**Table 6-9 MFUTP EEPROM Words**

| Offset | Bits | Description                             | Reserved |
|--------|------|-----------------------------------------|----------|
| 0x15   | 15:0 | LAN UDP/TCP Flexible Filter Value Port0 |          |
| 0x16   | 15:0 | LAN UDP/TCP Flexible Filter Value Port1 |          |
| 0x17   | 15:0 | LAN UDP/TCP Flexible Filter Value Port2 |          |
| 0x18   | 15:0 | LAN UDP/TCP Flexible Filter Value Port3 |          |
| 0x19   | 15:0 | LAN UDP/TCP Flexible Filter Value Port4 |          |
| 0x1A   | 15:0 | LAN UDP/TCP Flexible Filter Value Port5 |          |
| 0x1B   | 15:0 | LAN UDP/TCP Flexible Filter Value Port6 |          |
| 0x1C   | 15:0 | LAN UDP/TCP Flexible Filter Value Port7 |          |

### 6.3.8.14 Reserved EEPROM Words - Offset 0x1D - 0x24

EEPROM words at offsets 0x1D to 0x24 are reserved.

### 6.3.8.15 LAN 0/1/2/3 VLAN Filter 0 - 7; (MAVTV Registers) — Offset 0x25 — 0x2C

The words depicted in [Table 6-9](#) are loaded by Firmware to the *MAVTV* registers. Refer to [Section 8.21.1](#) for a description of the register.

**Table 6-10 MAVTV EEPROM Words**

| Offset | Bits  | Description                     | Reserved |
|--------|-------|---------------------------------|----------|
| 0x25   | 15:12 | Reserved                        |          |
| 0x25   | 11:0  | LAN 0/1/2/3 VLAN Filter 0 Value |          |
| 0x26   | 15:12 | Reserved                        |          |
| 0x26   | 11:0  | LAN 0/1/2/3 VLAN Filter 1 Value |          |
| 0x27   | 15:12 | Reserved                        |          |

| Offset | Bits  | Description                     | Reserved |
|--------|-------|---------------------------------|----------|
| 0x27   | 11:0  | LAN 0/1/2/3 VLAN Filter 2 Value |          |
| 0x28   | 15:12 | Reserved                        |          |
| 0x28   | 11:0  | LAN 0/1/2/3 VLAN Filter 3 Value |          |
| 0x29   | 15:12 | Reserved                        |          |
| 0x29   | 11:0  | LAN 0/1/2/3 VLAN Filter 4 Value |          |
| 0x2A   | 15:12 | Reserved                        |          |
| 0x2A   | 11:0  | LAN 0/1/2/3 VLAN Filter 5 Value |          |
| 0x2B   | 15:12 | Reserved                        |          |
| 0x2B   | 11:0  | LAN 0/1/2/3 VLAN Filter 6 Value |          |
| 0x2C   | 15:12 | Reserved                        |          |
| 0x2C   | 11:0  | LAN 0/1/2/3 VLAN Filter 7 Value |          |

### 6.3.8.16 Reserved EEPROM Words - Offset 0x2D to 0x2E

EEPROM words at offsets 0x2D to 0x2E are reserved.

### 6.3.8.17 LAN 0/1/2/3 MANC value LSB; (LMANC LSB) — Offset 0x2F

The value in this EEPROM word will be stored in the LSB word of the MANC register. Refer to [Section 8.21.4](#) for a description of this register.

| Bits | Name     | Default | Description | Reserved |
|------|----------|---------|-------------|----------|
| 15:0 | Reserved | 0x0     | Reserved    |          |

### 6.3.8.18 LAN 0/1/2/3 MANC Value MSB; (LMANC MSB) — Offset 0x30

The value in this EEPROM word will be stored in the MSB word of the MANC register. Refer to [Section 8.21.4](#) for a description of this register.

| Bits  | Name           | Default | Description                                                                                                                                                                                                    | Reserved |
|-------|----------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15    | Reserved       |         | Reserved.                                                                                                                                                                                                      |          |
| 14    | MPROXYE        | 0b      | Management Proxying Enable<br>When set to 1b Proxying of packets is enabled when device is in D3 low power state.<br>Bit loaded to MANC.MPROXYE bit (refer to <a href="#">Section 8.21.4</a> ).                |          |
| 13:11 | Reserved       |         | Reserved.                                                                                                                                                                                                      |          |
| 10    | NET_TYPE       | 0b      | NET TYPE:<br>0b = pass only un-tagged packets.<br>1b = pass only VLAN tagged packets.<br>Valid only if FIXED_NET_TYPE is set.                                                                                  |          |
| 9     | FIXED_NET_TYPE | 0b      | Fixed net type<br>If set, only packets matching the net type defined by the NET_TYPE field passes to manageability. Otherwise, both tagged and un-tagged packets can be forwarded to the manageability engine. |          |

| Bits | Name           | Default | Description                                                                                                                                                                                         | Reserved |
|------|----------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 8    | EN_IPv4_FILTER | 0b      | Enable IPv4 address Filters<br>When set, the last 128 bits of the <i>MIPAF</i> register are used to store 4 IPv4 addresses for IPv4 filtering. When cleared, these bits store a single IPv6 filter. |          |
| 7    | EN_XSUM_FILTER | 0b      | Enable checksum filtering to MNG<br>When this bit is set, only packets that pass L3, L4 checksum are sent to the Management Controller.                                                             |          |
| 6:0  | Reserved       |         | Reserved.<br>Value should be 0.                                                                                                                                                                     |          |

### 6.3.8.20 LAN 0/1/2/3 Receive Enable 2; (LRXEN2) — Offset 0x32

| Bits | Name                   | Default | Description    | Reserved |
|------|------------------------|---------|----------------|----------|
| 15:8 | Receive Enable byte 14 | 0x0     | Alert Value    |          |
| 7:0  | Receive Enable byte 13 | 0x0     | Interface Data |          |

### 6.3.8.21 LAN 0/1/2/3 MNGONLY LSB; (LMNGONLY LSB) - Offset 0x33

The value in this EEPROM word will be stored in the LSB word of the *MNGONLY* register. Refer to [Section 8.21.5](#) for a description of this register.

| Bits | Name             | Default | Description                                                                                                                                                                                                                                        | Reserved |
|------|------------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:8 | Reserved         |         |                                                                                                                                                                                                                                                    |          |
| 7:0  | Exclusive to MNG |         | Exclusive to MNG – when set, indicates that packets forwarded by the manageability filters to manageability are not sent to the host. Bits 0...7 correspond to decision rules defined in registers <i>MDEF[0...7]</i> and <i>MDEF_EXT[0...7]</i> . |          |

### 6.3.8.22 LAN 0/1/2/3 MNGONLY MSB; (LMNGONLY MSB) - Offset 0x34

The value in this EEPROM word will be stored in the MSB word of the *MNGONLY* register. Refer to [Section 8.21.5](#) for a description of this register.

| Bits | Name     | Default | Description | Reserved |
|------|----------|---------|-------------|----------|
| 15:0 | Reserved | 0x0     | Reserved    |          |

### 6.3.8.23 Manageability Decision Filters 0 LSB; (MDEF0 LSB) - Offset 0x35

The value in this EEPROM word will be stored in the LSB word of the *MDEF[0]* register. Refer to [Section 8.21.6](#) for a description of this register.

| Bits | Name    | Default | Description                                      | Reserved |
|------|---------|---------|--------------------------------------------------|----------|
| 15:0 | MDEF0_L |         | Loaded to 16 LS bits of <i>MDEF[0]</i> register. |          |

### 6.3.8.24 Manageability Decision Filters 0 MSB; (MDEF0 MSB) - Offset 0x36

The value in this EEPROM word will be stored in the MSB word of the *MDEF[0]* register. Refer to [Section 8.21.6](#) for a description of this register.

| Bits | Name    | Default | Description                                      | Reserved |
|------|---------|---------|--------------------------------------------------|----------|
| 15:0 | MDEF0_M |         | Loaded to 16 MS bits of <i>MDEF[0]</i> register. |          |

### 6.3.8.25 Manageability Decision Filters Extend 0 LSB; (MDEF\_EXT0 LSB) - Offset 0x37

The value in this EEPROM word will be stored in the LSB word of the *MDEF\_EXT[0]* register. Refer to [Section 8.21.7](#) for a description of this register.

| Bits | Name       | Default | Description                                          | Reserved |
|------|------------|---------|------------------------------------------------------|----------|
| 15:0 | MDEFEXT0_L |         | Loaded to 16 LS bits of <i>MDEF_EXT[0]</i> register. |          |

#### 6.3.8.26 Manageability Decision Filters Extend 0 MSB; (MDEF\_EXT0 MSB) - Offset 0x38

The value in this EEPROM word will be stored in the MSB word of the *MDEF\_EXT[0]* register. Refer to [Section 8.21.7](#) for a description of this register.

| Bits | Name       | Default | Description                                          | Reserved |
|------|------------|---------|------------------------------------------------------|----------|
| 15:0 | MDEF0EXT_M |         | Loaded to 16 MS bits of <i>MDEF_EXT[0]</i> register. |          |

#### 6.3.8.27 Manageability Decision Filters; (MDEF1-6 and MDEF\_EXT1-6) - Offset 0x39-0x50

Same as words 0x035...0x38 for *MDEF[1]* and *MDEF\_EXT[1]*...*MDEF[6]* and *MDEF\_EXT[6]*

#### 6.3.8.28 Manageability Ethertype Filter 0 LSB; (METF0 LSB) - Offset 0x51

The value in this EEPROM word will be stored in the LSB word of the *METF[0]* register. Refer to [Section 8.21.3](#) for a description of this register.

| Bits | Name    | Default | Description                                      | Reserved |
|------|---------|---------|--------------------------------------------------|----------|
| 15:0 | METF0_L |         | Loaded to 16 LS bits of <i>METF[0]</i> register. |          |

#### 6.3.8.29 Manageability Ethertype Filter 0 MSB; (METF0 MSB) - Offset 0x52

The value in this EEPROM word will be stored in the MSB word of the *METF[0]* register. Refer to [Section 8.21.3](#) for a description of this register.

| Bits | Name    | Default | Description                                                                                                                                                | Reserved |
|------|---------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | METF0_M |         | Loaded to 16 MS bits of <i>METF[0]</i> register (reserved bits in the <i>METF</i> registers should be set in the EEPROM to the register's default values). |          |

#### 6.3.8.30 Manageability Ethertype Filter 1...3; (METF1...3) - Offset 0x53...0x58

Same as words 0x51 and 0x52 for *METF[1]*...*METF[3]* registers.

### 6.3.8.31 ARP Response IPv4 Address 0 LSB; (ARP LSB) - Offset 0x59

| Bits | Name                                | Default | Description                                         | Reserved |
|------|-------------------------------------|---------|-----------------------------------------------------|----------|
| 15:0 | ARP Response IPv4 Address 0, Byte 1 |         | ARP Response IPv4 Address 0, Byte 1 (firmware use). |          |
| 7:0  | ARP Response IPv4 Address 0, Byte 0 |         | ARP Response IPv4 Address 0, Byte 0 (firmware use). |          |

### 6.3.8.32 ARP Response IPv4 Address 0 MSB; (ARP MSB) - Offset 0x5A

| Bits | Name                                | Default | Description                                         | Reserved |
|------|-------------------------------------|---------|-----------------------------------------------------|----------|
| 15:8 | ARP Response IPv4 Address 0, Byte 3 |         | ARP Response IPv4 Address 0, Byte 3 (firmware use). |          |
| 7:0  | ARP Response IPv4 Address 0, Byte 2 |         | ARP Response IPv4 Address 0, Byte 2 (firmware use). |          |

### 6.3.8.33 LAN0/1/2/3 IPv6 Address 0 LSB; (MIPAF0 LSB) - Offset 0x5B

This value will be stored in the *MIPAF[0]* register (0x58B0). Refer to [Section 8.21.8](#) for a description of this register.

| Bits | Name                      | Default | Description               | Reserved |
|------|---------------------------|---------|---------------------------|----------|
| 15:8 | LAN IPv6 Address 0 Byte 1 |         | LAN IPv6 Address 0 Byte 1 |          |
| 7:0  | LAN IPv6 Address 0 Byte 0 |         | LAN IPv6 Address 0 Byte 0 |          |

### 6.3.8.34 LAN0/1/2/3 IPv6 Address 0 MSB; (MIPAF0 MSB) - Offset 0x5C

This value will be stored in the *MIPAF[0]* register (0x58B0). Refer to [Section 8.21.8](#) for a description of this register.

| Bits | Name                      | Default | Description               | Reserved |
|------|---------------------------|---------|---------------------------|----------|
| 15:8 | LAN IPv6 Address 0 Byte 3 |         | LAN IPv6 Address 0 Byte 3 |          |
| 7:0  | LAN IPv6 Address 0 Byte 2 |         | LAN IPv6 Address 0 Byte 2 |          |

### 6.3.8.35 LAN0/1/2/3 IPv6 Address 0 LSB; (MIPAF1 LSB)- Offset 0x5D

This value will be stored in the *MIPAF[1]* register (0x58B4). Refer to [Section 8.21.8](#) for a description of this register.

| Bits | Name                      | Default | Description               | Reserved |
|------|---------------------------|---------|---------------------------|----------|
| 15:8 | LAN IPv6 Address 0 Byte 5 |         | LAN IPv6 Address 0 Byte 5 |          |
| 7:0  | LAN IPv6 Address 0 Byte 4 |         | LAN IPv6 Address 0 Byte 4 |          |

### 6.3.8.36 LAN0/1/2/3 IPv6 Address 0 MSB; (MIPAF1 MSB) - Offset 0x5E

This value will be stored in the *MIPAF[1]* register (0x58B4). Refer to [Section 8.21.8](#) for a description of this register.

| Bits | Name                      | Default | Description               | Reserved |
|------|---------------------------|---------|---------------------------|----------|
| 15:8 | LAN IPv6 Address 0 Byte 7 |         | LAN IPv6 Address 0 Byte 7 |          |
| 7:0  | LAN IPv6 Address 0 Byte 6 |         | LAN IPv6 Address 0 Byte 6 |          |

### 6.3.8.37 LAN0/1/2/3 IPv6 Address 0 LSB; (MIPAF2 LSB) - Offset 0x5F

This value will be stored in the *MIPAF[2]* register (0x58B8). See [Section 8.21.8](#) for a description of this register.

| Bits | Name                      | Default | Description               | Reserved |
|------|---------------------------|---------|---------------------------|----------|
| 15:8 | LAN IPv6 Address 0 Byte 9 |         | LAN IPv6 Address 0 Byte 9 |          |
| 7:0  | LAN IPv6 Address 0 Byte 8 |         | LAN IPv6 Address 0 Byte 8 |          |

### 6.3.8.38 LAN0/1/2/3 IPv6 Address 0 MSB; (MIPAF2 MSB) - Offset 0x60

This value will be stored in the *MIPAF[2]* register (0x58B8). Refer to [Section 8.21.8](#) for a description of this register.

| Bits | Name                       | Default | Description                | Reserved |
|------|----------------------------|---------|----------------------------|----------|
| 15:8 | LAN IPv6 Address 0 Byte 11 |         | LAN IPv6 Address 0 Byte 11 |          |
| 7:0  | LAN IPv6 Address 0 Byte 10 |         | LAN IPv6 Address 0 Byte 10 |          |

### 6.3.8.39 LAN0/1/2/3 IPv6 Address 0 LSB; (MIPAF3 LSB) - Offset 0x61

This value will be stored in the *MIPAF[3]* register (0x58BC). Refer to [Section 8.21.8](#) for a description of this register.

| Bits | Name                       | Default | Description                | Reserved |
|------|----------------------------|---------|----------------------------|----------|
| 15:8 | LAN IPv6 Address 0 Byte 13 |         | LAN IPv6 Address 0 Byte 13 |          |
| 7:0  | LAN IPv6 Address 0 Byte 12 |         | LAN IPv6 Address 0 Byte 12 |          |

#### 6.3.8.40 LAN0/1/2/3 IPv6 Address 0 MSB; (MIPAF3 MSB) - Offset 0x62

This value will be stored in the *MIPAF[3]* register (0x58BC). Refer to [Section 8.21.8](#) for a description of this register.

| Bits | Name                       | Default | Description                | Reserved |
|------|----------------------------|---------|----------------------------|----------|
| 15:8 | LAN IPv6 Address 0 Byte 15 |         | LAN IPv6 Address 0 Byte 15 |          |
| 7:0  | LAN IPv6 Address 0 Byte 14 |         | LAN IPv6 Address 0 Byte 14 |          |

#### 6.3.8.41 LAN0/1/2/3 IPv6 Address 1; MIPAF (Offset 0x63:0x6A)

Same structure as LAN0/1/2/3 IPv6 Address 0.

These value are stored in the *MIPAF[7:4]* registers (0x58C0 - 0x58CC).

#### 6.3.8.42 LAN0/1/2/3 IPv6 Address 2; MIPAF (Offset 0x6B:0x72)

Same structure as LAN01/2/3 IPv6 Address 0.

These value are stored in the *MIPAF[11:8]* registers (0x58D0 - 0x58DC).

### 6.3.9 Sideband Configuration Module (Global MNG Offset 0x06)

This module is pointed to by global offset 0x06 of the manageability control table.

#### 6.3.9.1 Section Header — Offset 0x0

| Bits | Name         | Default | Description              | Reserved |
|------|--------------|---------|--------------------------|----------|
| 15:8 | Block CRC8   |         |                          |          |
| 7:0  | Block Length | 0x0E    | Section length in words. |          |

### 6.3.9.2 SMBus Maximum Fragment Size — Offset 0x01

| Bits | Name              | Default | Description                                                                                                                                                                              | Reserved |
|------|-------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | Max Fragment Size | 0x20    | SMBus Maximum Fragment Size (bytes).<br>Note: Value should be in the 32 to 240 Byte range.<br>In MCTP mode, this value should be set to 0x45 (64 bytes payload + 5 bytes of MCTP header) |          |

### 6.3.9.3 SMBus Notification Timeout and Flags — Offset 0x02

| Bits | Name                            | Default | Description                                                                                                                                                                                                                                    | Reserved |
|------|---------------------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:8 | SMBus Notification Timeout (ms) | 0xFF    | SMBus Notification Timeout<br>Timeout value in milliseconds from notification to completion of packet read by the external BMC. When completion of read exceeds the specified time packet is discarded.<br><b>Note:</b> A value 0, no discard. |          |
| 7:6  | SMBus Connection Speed          | 00b     | Defines the clock speed when accessing the bus as a master.<br>00b = Standard SMBus connection (100 KHz).<br>01b = Reserved.<br>10b = Reserved.<br>11b = Reserved                                                                              |          |
| 5    | SMBus Block Read Command        | 0b      | 0b = Block read command is 0xC0.<br>1b = Block read command is 0xD0.                                                                                                                                                                           |          |
| 4    | SMBus Addressing Mode           | 1b      | 0b = Single address mode.<br>1b = Multi address mode.                                                                                                                                                                                          |          |
| 3    | Enable fairness arbitration     | 1b      | 0b = Disable fairness arbitration.<br>1b = Enable fairness arbitration.                                                                                                                                                                        |          |
| 2    | Disable SMBus ARP Functionality | 1b      | Disable SMBus ARP Functionality<br>0b = Enable SMBus ARP Functionality.<br>1b = Disable SMBus ARP Functionality.                                                                                                                               |          |
| 1    | SMBus ARP PEC                   | 1b      | SMBus ARP PEC<br>0b = Disable SMBus ARP PEC.<br>1b = Enable SMBus ARP PEC.                                                                                                                                                                     |          |
| 0    | Reserved                        |         | Reserved                                                                                                                                                                                                                                       |          |

### 6.3.9.4 SMBus Slave Addresses 1 — Offset 0x03

| Bits | Name                  | Default | Description                                                    | Reserved |
|------|-----------------------|---------|----------------------------------------------------------------|----------|
| 15:9 | SMBus 1 Slave Address | 0x4A    | SMBus 1 Slave Address<br><b>Note:</b> Multi address mode only. |          |
| 8    | Reserved              | 0b      | Reserved                                                       |          |
| 7:1  | SMBus 0 Slave Address | 0x49    | SMBus 0 Slave Address                                          |          |
| 0    | Reserved              | 0b      | Reserved                                                       |          |

### 6.3.9.5 Reserved — Offset 0x04

### 6.3.9.6 Reserved — Offset 0x05

| Bits | Name     | Default | Description | Reserved |
|------|----------|---------|-------------|----------|
| 15:0 | Reserved | 0x0     | Reserved    |          |

| Bits | Name     | Default | Description | Reserved |
|------|----------|---------|-------------|----------|
| 15:0 | Reserved | 0x0     | Reserved    |          |

### 6.3.9.7 NC-SI Configuration - Offset 0x06

| Bits  | Name                              | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                | Reserved |

### 6.3.9.9 NC-SI Hardware Arbitration Configuration - Offset 0x08

| Bits | Name          | Default | Description                                                                                                                                                                                                                                                                                                                                           |  |
|------|---------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| 15:0 | Token Timeout | 0xFFFF  | NC-SI HW-Arbitration TOKEN Timeout (in 16 ns cycles). In order to get the value if NC-SI REF_CLK cycles, this field should be multiplied by 5/4.<br><b>Notes:</b><br>1. Setting value to 0 disables the timeout mechanism.<br>2. The timeout shall be no fewer than 32,000 REF_CLK cycles (i.e. value of field should be greater or equal to 0x9C40). |  |

### 6.3.9.10 MCTP UUID - Time Low LSB (Offset 0x09)

The value stored in the MCTP UUID register should indicate the creation date of the image or an earlier arbitrary date.

| Bits | Name         | Default | Description                              | Reserved |
|------|--------------|---------|------------------------------------------|----------|
| 15:0 | time low LSB |         | Byte 0 & 1 of UUID as defined in DSP0236 |          |

### 6.3.9.11 MCTP UUID - Time Low MSB (Offset 0x0A)

| Bits | Name         | Default | Description                              | Reserved |
|------|--------------|---------|------------------------------------------|----------|
| 15:0 | time low MSB |         | Byte 2 & 3 of UUID as defined in DSP0236 |          |

### 6.3.9.12 MCTP UUID - Time MID (Offset 0x0B)

| Bits | Name     | Default | Description                              | Reserved |
|------|----------|---------|------------------------------------------|----------|
| 15:0 | time mid |         | Byte 4 & 5 of UUID as defined in DSP0236 |          |

### 6.3.9.13 MCTP UUID - Time High and Version (Offset 0x0C)

| Bits | Name                  | Default | Description                              | Reserved |
|------|-----------------------|---------|------------------------------------------|----------|
| 15:0 | time high and version |         | Byte 7 & 8 of UUID as defined in DSP0236 |          |

### 6.3.9.14 MCTP UUID - Clock Seq (Offset 0x0D)

| Bits | Name                   | Default | Description                               | Reserved |
|------|------------------------|---------|-------------------------------------------|----------|
| 15:0 | Clock seq and reserved |         | Byte 9 & 10 of UUID as defined in DSP0236 |          |

### 6.3.9.15 SMBus Slave Addresses 2 - Offset 0x0E

| Bits | Name                  | Default | Description                                                    | Reserved |
|------|-----------------------|---------|----------------------------------------------------------------|----------|
| 15:9 | SMBus 3 Slave Address | 0x4C    | SMBus 3 Slave Address<br><b>Note:</b> Multi address mode only. |          |
| 8    | Reserved              | 0b      | Reserved                                                       |          |
| 7:1  | SMBus 2 Slave Address | 0x4B    | SMBus 2 Slave Address<br><b>Note:</b> Multi address mode only. |          |
| 0    | Reserved              | 0b      | Reserved                                                       |          |

### 6.3.9.16 Alternative IANA - Offset 0x0F

| Bits | Name                    | Default | Description                                                                               |  |
|------|-------------------------|---------|-------------------------------------------------------------------------------------------|--|
| 15:0 | Alternative IANA number | 0x0     | If not zero and not 0x157, the I350 will accept NC-SI OEM commands with this IANA number. |  |

### 6.3.9.17 NC-SI over MCTP Configuration - Offset 0x10

| Bits | Name              | Default | Description                                                                                      |    |
|------|-------------------|---------|--------------------------------------------------------------------------------------------------|----|
| 15:8 | NC-SI packet type | 0x2     | Defines the MCTP packet type used to identify NC-SI packets                                      | No |
| 7    | Simplified MCTP   | 0x0     | If set, only SOM and EOM bits are used for the re-assembly process. Relevant only in SMBus mode. | No |
| 6:0  | Reserved          | 0x0     | Reserved                                                                                         | No |

## 6.3.10 Flexible TCO Filter Configuration Module (Global MNG Offset 0x07)

This module is pointed to by global offset 0x07 of the manageability control section.

### 6.3.10.1 Section Header — Offset 0x0

| Bits | Name         | Default | Description              | Reserved |
|------|--------------|---------|--------------------------|----------|
| 15:8 | Block CRC8   |         |                          |          |
| 7:0  | Block Length |         | Section length in words. |          |

### 6.3.10.2 Flexible Filter Length and Control — Offset 0x01

| Bits | Name                           | Default | Description                                                                        | Reserved |
|------|--------------------------------|---------|------------------------------------------------------------------------------------|----------|
| 15:8 | Flexible Filter Length (Bytes) |         | Flexible Filter Length in Bytes.                                                   |          |
| 7    | Reserved                       |         | Reserved                                                                           |          |
| 6    | Apply Filter to LAN 3          |         | Apply Filter to LAN 3<br>0b - Do not apply Flex Filter.<br>1b - Apply Flex Filter. |          |

| Bits | Name                  | Default | Description                                                                        | Reserved |
|------|-----------------------|---------|------------------------------------------------------------------------------------|----------|
| 5    | Apply Filter to LAN 2 |         | Apply Filter to LAN 2<br>0b - Do not apply Flex Filter.<br>1b - Apply Flex Filter. |          |
| 4    | Last Filter           | 1b      | Last Filter                                                                        |          |
| 3:2  | Filter Index (0)      | 0x0     | Filter Index                                                                       |          |
| 1    | Apply Filter to LAN 1 |         | Apply Filter to LAN 1<br>0b - Do not apply Flex Filter.<br>1b - Apply Flex Filter. |          |
| 0    | Apply Filter to LAN 0 |         | Apply Filter to LAN 0<br>0b - Do not apply Flex Filter.<br>1b - Apply Flex Filter. |          |

### 6.3.10.3 Flexible Filter Enable Mask — Offset 0x02 – 0x09

| Bits | Name                        | Default | Description                                                                                                  | Reserved |
|------|-----------------------------|---------|--------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | Flexible Filter Enable Mask |         | Flexible Filter Enable Mask<br>Up to 128 Flex filter mask bits for Bytes defined in the Flexible Filter Data |          |

### 6.3.10.4 Flexible Filter Data — Offset 0x0A – Block Length

| Bits | Name                 | Default | Description                                                              | Reserved |
|------|----------------------|---------|--------------------------------------------------------------------------|----------|
| 15:0 | Flexible Filter Data |         | Flexible Filter Data<br>Up to 128 Bytes of data starting at offset 0x0A. |          |

**Note:** This section loads all of the flexible filters, The control + mask + filter data are repeatable as the number of filters. Section length in offset 0 is for all filters.

## 6.3.11 NC-SI Configuration Module (Global MNG Offset 0x0A)

This module is pointed to by global offset 0x0A of the manageability control table.

### 6.3.11.1 Section Header — Offset 0x0

| Bits | Name         | Default | Description              | Reserved |
|------|--------------|---------|--------------------------|----------|
| 15:8 | Block CRC8   |         |                          |          |
| 7:0  | Block Length | 0x9     | Section length in words. |          |

### 6.3.11.2 Rx Mode Control1 (RR\_CTRL[15:0]) - Offset 0x1

| Bits | Name                  | Default | Description                                                                                                                                   | Reserved |
|------|-----------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:1 | Reserved              |         | Set to 0x0.                                                                                                                                   |          |
| 0    | NC-SI Loopback Enable |         | When set, enables NC-SI TX to RX loop. All data that is transmitted from NC-SI is returned to it. No data is actually transmitted from NC-SI. |          |

### 6.3.11.3 Rx Mode Control2 (RR\_CTRL[31:16]) - Offset 0x2

| Bits | Name     | Default | Description | Reserved |
|------|----------|---------|-------------|----------|
| 15:0 | Reserved | 0x0     |             |          |

### 6.3.11.4 Tx Mode Control1 (RT\_CTRL[15:0]) - Offset 0x3

| Bits | Name     | Default | Description | Reserved |
|------|----------|---------|-------------|----------|
| 15:0 | Reserved |         | Set to 0x0. |          |

### 6.3.11.5 Tx Mode Control2 (RT\_CTRL[31:16]) - Offset 0x4

| Bits | Name     | Default | Description | Reserved |
|------|----------|---------|-------------|----------|
| 15:0 | Reserved | 0x0     | Set to 0x0. |          |

### 6.3.11.6 MAC Tx Control Reg1 (TxCtrlReg1 (15:0]) - Offset 0x5

| Bits | Name       | Default | Description                                          | Reserved |
|------|------------|---------|------------------------------------------------------|----------|
| 15:5 | Reserved   | 0x0     | Set to 0x0.                                          |          |
| 4    | Append_fcs |         | When set, computes and appends the FCS on Tx frames. |          |
| 3:0  | Reserved   |         | Reserved                                             |          |

### 6.3.11.7 MAC Tx Control Reg2 (TxCtrlReg1 (31:16]) - Offset 0x6

| Bits | Name     | Default | Description                   | Reserved |
|------|----------|---------|-------------------------------|----------|
| 15:0 | Reserved |         | Reserved Should be set to 0b. |          |

### 6.3.11.8 MAC RX Buffer Size - Offset 0x7

| Bits | Name           | Default | Description                                                                                                                                                                                                                      | Reserved |
|------|----------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | RX Buffer size |         | Per port Buffer size allocated to Data received from the BMC in KBytes.<br><b>Notes:</b><br>1. In SMBus and MCTP operating mode value must be 0x4.<br>2. In NCSI operating mode value should be at least 0x6 and not exceed 0x8. |          |

### 6.3.11.9 NCSI Flow Control XOFF - Offset 0x8

| Bits | Name           | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Reserved |
|------|----------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | XOFF Threshold |         | TX Buffer watermark for sending a XOFF NC-SI flow control packet in Bytes. The <i>XOFF Threshold</i> value refers to the occupied space in the buffer.<br><b>Notes:</b><br>1. Field relevant for NCSI operation mode only.<br>2. To support maximum packet size of 1.5 KBytes, Value programmed should be:<br><i>TX Buffer size</i> (refer to <a href="#">Section 6.3.11.8</a> ) - 3,400 Bytes<br>a. When <i>TX Buffer size</i> is 6 KBytes value of field should be 0xAB8 (2,744 Bytes) |          |

### 6.3.11.10 NCSI Flow Control XON - Offset 0x9

| Bits | Name          | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Reserved |
|------|---------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 15:0 | XON Threshold |         | TX Buffer water mark for sending a XON NC-SI flow control packet in Bytes. The <i>XON Threshold</i> value refers to the available space in the TX buffer<br><b>Notes:</b><br>1. Field relevant for NCSI operation mode only.<br>2. To support maximum packet size of 1.5 KBytes, Value programmed should be a positive value that equals:<br><i>TX Buffer size</i> (refer to <a href="#">Section 6.3.11.8</a> ) - <i>XOFF Threshold</i> (refer to <a href="#">Section 6.3.11.9</a> ) + 1536 Bytes.<br>a. When the <i>TX Buffer size</i> is 6 KBytes and the <i>XOFF Threshold</i> is 2,744 Bytes value of field should be 0x1348 (4,936 Bytes). |          |

## 6.3.12 Traffic Type Parameters – (Global MNG Offset 0xB)

### 6.3.12.1 Section Header — Offset 0x0

| Bits | Name         | Default | Description              | Reserved |
|------|--------------|---------|--------------------------|----------|
| 15:8 | Block CRC8   |         |                          |          |
| 7:0  | Block Length | 0x1     | Section length in words. |          |

### 6.3.12.2 Traffic Type Data - Offset 0x1

| Bits  | Name                 | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|----------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:14 | Reserved             |         | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 6.3.13 PHY Configuration Pointer – (Global MNG Offset 0xF)

| Bit  | Name    | Description                                                                                                                                                     |
|------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | Pointer | Pointer to PHY configuration structure. Refer to <a href="#">Section 6.3.13.1</a> for details of the structure. A value of 0xFFFF means the pointer is invalid. |

#### 6.3.13.1 PHY Configuration Structure

This section describes the PHY auto configuration structure used to configure PHY related circuitry. The programming in this section is applied after each PHY reset.

The PHY Configuration Pointer Global MNG Offset 0xF) points to the start (offset 0x0) of this type of structure, to configure PHY registers (Internal and External PHYs). If pointer is 0xFFFF then no structure exists.

**Table 6-11 PHY Auto Configuration Structure Format**

| Offset  | High Byte[15:8]                                             | Low Byte[7:0] | Section                            |
|---------|-------------------------------------------------------------|---------------|------------------------------------|
| 0x0     | Section Length = 2*n (n – number of registers to configure) |               | <a href="#">Section 6.3.13.1.1</a> |
| 0x1     | Block CRC8                                                  |               | <a href="#">Section 6.3.13.1.2</a> |
| 0x2     | PHY number and PHY register address                         |               | <a href="#">Section 6.3.13.1.3</a> |
| 0x3     | PHY data (MDIC[15:0] or I2CCMD[15:0])                       |               | <a href="#">Section 6.3.13.1.4</a> |
|         | ...                                                         |               |                                    |
| 2*n     | PHY number and PHY register address                         |               | <a href="#">Section 6.3.13.1.3</a> |
| 2*n + 1 | PHY data (MDIC[15:0] or I2CCMD[15:0])                       |               | <a href="#">Section 6.3.13.1.4</a> |

##### 6.3.13.1.1 PHY Configuration Section Length - Offset 0x0

The section length word contains the length of the section in words. Note that section length count does not include the section length word and Block CRC8 word.

| Bits | Name           | Default | Description              |
|------|----------------|---------|--------------------------|
| 15   | Reserved       |         |                          |
| 14:0 | Section_length |         | Section length in words. |

##### 6.3.13.1.2 Block CRC8 (Offset 0x1)

| Bit  | Name     | Description |
|------|----------|-------------|
| 15:8 | Reserved |             |
| 7:0  | CRC8     |             |

### 6.3.13.1.3 PHY Number and PHY Register Address - (Offset 2\*n; [n = 1... Section Length])

| Bits  | Name                 | Default | Description                                                                                                                                                                                                                                                                        |
|-------|----------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:12 | Reserved             | 0x0     | Reserved                                                                                                                                                                                                                                                                           |
| 11    | Apply to port 3      |         | If set, apply to programming when the PHY of port three is reset.                                                                                                                                                                                                                  |
| 10    | Apply to port 2      |         | If set, apply to programming when the PHY of port two is reset.                                                                                                                                                                                                                    |
| 9     | Apply to port 1      |         | If set, apply to programming when the PHY of port one is reset.                                                                                                                                                                                                                    |
| 8     | Apply to port 0      |         | If set, apply to programming when the PHY of port zero is reset.                                                                                                                                                                                                                   |
| 7:0   | PHY register address |         | PHY register address to which the data is written.<br>See <a href="#">Section 8.2.4</a> and <a href="#">Section 8.17.8</a> for information on the MDIC and I2CCMD registers respectively.<br><b>Note:</b> 5 LSB bits define register address when access is via the MDIC register. |

### 6.3.13.1.4 PHY data (Offset 2\*n + 1; [n = 1... Section Length])

| Bits | Name     | Default | Description                                                                                                                                                           |
|------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | Reg_Data |         | MDIC[15:0]/I2CCMD[15:0] value (Data).<br>See <a href="#">Section 8.2.4</a> and <a href="#">Section 8.17.8</a> for information MDIC and I2CCMD registers respectively. |

## 6.3.14 Thermal Sensor Configuration Pointer – (Global MNG Offset 0x10)

| Bit  | Name    | Description                                                                                                                                                                |
|------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | Pointer | Pointer to Thermal Sensor configuration structure. Refer to <a href="#">Section 6.3.14.1</a> for details of the structure. A value of 0xFFFF means the pointer is invalid. |

### 6.3.14.1 Thermal Sensor Configuration Structure

This section describes the PHY auto configuration structure used to configure Thermal Sensor related circuitry. The programming in this section is applied after power-up or Thermal Sensor reset.

The [Thermal Sensor Configuration Pointer – \(Global MNG Offset 0x10\)](#) points to the start (offset 0x0) of this type of structure, to configure Thermal Sensor registers. If pointer is 0xFFFF then no structure exists.

**Table 6-12 Thermal Sensor Auto Configuration Structure Format**

| Offset | High Byte[15:8]                                             | Low Byte[7:0] | Section                            |
|--------|-------------------------------------------------------------|---------------|------------------------------------|
| 0x0    | Section Length = 2*n (n – number of registers to configure) |               | <a href="#">Section 6.3.14.1.1</a> |
| 0x1    | Block CRC8                                                  |               | <a href="#">Section 6.3.14.1.2</a> |
| 0x2    | Thermal Sensor register address                             |               | <a href="#">Section 6.3.14.1.3</a> |
| 0x3    | Thermal Sensor data                                         |               | <a href="#">Section 6.3.14.1.4</a> |

**Table 6-12 Thermal Sensor Auto Configuration Structure Format**

| Offset  | High Byte[15:8]                 | Low Byte[7:0] | Section            |
|---------|---------------------------------|---------------|--------------------|
|         | ...                             |               |                    |
| 2*n     | Thermal Sensor register address |               | Section 6.3.14.1.3 |
| 2*n + 1 | Thermal Sensor data             |               | Section 6.3.14.1.4 |

#### 6.3.14.1.1 Thermal Sensor Configuration Section Length - Offset 0x0

The section length word contains the length of the section in words. Note that section length count does not include the section length word and Block CRC8 word.

| Bits | Name           | Default | Description              |
|------|----------------|---------|--------------------------|
| 15   | Reserved       |         |                          |
| 14:0 | Section_length |         | Section length in words. |

#### 6.3.14.1.2 Block CRC8 (Offset 0x1)

| Bit  | Name     | Description |
|------|----------|-------------|
| 15:8 | Reserved |             |
| 7:0  | CRC8     |             |

#### 6.3.14.1.3 Thermal Sensor Register Address - (Offset 2\*n; [n = 1... Section Length])

| Bits | Name                            | Default | Description                                                   |
|------|---------------------------------|---------|---------------------------------------------------------------|
| 15:5 | Reserved                        | 0x0     | Reserved                                                      |
| 4:0  | Thermal Sensor register address |         | Thermal Sensor register address to which the data is written. |

#### 6.3.14.1.4 Thermal Sensor data (Offset 2\*n + 1; [n = 1... Section Length])

| Bits | Name     | Default | Description                   |
|------|----------|---------|-------------------------------|
| 15:0 | Reg_Data |         | Thermal Sensor register data. |

## 6.4 Software Accessed Words

Words 0x03 to 0x07 in the EEPROM image are reserved for compatibility information. New bits within these fields will be defined as the need arises for determining software compatibility between various hardware revisions.

Words 0x8 and 0x09 are used to indicate the Printed Board Assembly (PBA) number and words 0x42 and 0x43 identifies the EEPROM image.

Words 0x30 to 0x3E have been reserved for configuration and version values to be used by PXE code. The only exceptions are words 0x36 and 0x3D which are used for the iSCSI boot configuration and word 0x37 which is used as a pointer to the Alternate MAC address.

### 6.4.1 Compatibility (Word 0x03)

| Bit   | Description                                              |
|-------|----------------------------------------------------------|
| 15:12 | Reserved (set to 0000b).                                 |
| 11    | LOM/Not a LOM.<br>0b = NIC.<br>1b = LOM.                 |
| 10    | Reserved (set to 0b)                                     |
| 9     | Client/Not a Client NIC.<br>0b = Server.<br>1b = Client. |
| 8:0   | Reserved (set to 0x0)                                    |

### 6.4.2 Port Identification LED blinking (Word 0x04)

Driver software provides a method to identify an external port on a system through a command that causes the LEDs to blink. Based on the setting in word 0x4, the LED drivers should blink between STATE1 and STATE2 when a port identification command is issued.

When word 0x4 is equal to 0xFFFF or 0x0000, the blinking behavior reverts to a default.

| Bit   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 6.4.3 EEPROM Image Revision (Word 0x05)

This word is valid only for device starter images and indicates the ID and version of the EEPROM image.

| Bit   | Description           |
|-------|-----------------------|
| 15:12 | EEPROM major version. |
| 11:8  | Reserved              |
| 7:0   | EEPROM minor version. |

**Note:** The value shown is the decimal representation of the actual version. For example: 0x1044 = v1.44

### 6.4.4 OEM Specific (Word 0x06, 0x07)

These words are available for OEM use.

### 6.4.5 PBA Number/Pointer (Word 0x08, 0x09)

The nine-digit Printed Board Assembly (PBA) number used for Intel manufactured Network Interface Cards (NICs).

Current PBA numbers have exceeded the length that can be stored as hex values in these two words. For these PBA numbers the high word is a flag (0xFAFA) indicating that the PBA is stored in a separate PBA Block. The low word is a pointer to a PBA block.

| PBA Number | Word 0x8 | Word 0x9             |
|------------|----------|----------------------|
| G23456-003 | FAFA     | Pointer to PBA Block |

The PBA Block is pointed to by word 0x9:

| Word Offset | Description                                       | End User Reserved |
|-------------|---------------------------------------------------|-------------------|
| 0x0         | Length in words of the PBA Block (default is 0x6) | No                |
| 0x1.. 0x5   | PBA Number stored in hexadecimal ASCII values.    | No                |

The PBA block contains the complete PBA number including the dash and the first digit of the 3-digit suffix.

Example:

| PBA Number | Word Offset 0 | Word Offset 1 | Word Offset 2 | Word Offset 3 | Word Offset 4 | Word Offset 5 |
|------------|---------------|---------------|---------------|---------------|---------------|---------------|
| G23456-003 | 0006          | 4732          | 3334          | 3536          | 2D30          | 3033          |

For older products, the PBA number is stored directly in words 0x8/0x9. In this case, the PBA is stored in a four-byte field. The dash itself is not stored nor is the first digit of the 3-digit suffix, as it is always zero for the affected products.

Example:

| Product | PWA Number | Byte 1 | Byte 2 | Byte 3 | Byte 4 |
|---------|------------|--------|--------|--------|--------|
| Example | 123456-003 | 12     | 34     | 56     | 03     |

Note that through the course of hardware ECOs, the suffix field (byte 4/6) increments. The purpose of this information is to allow customer support (or any user) to identify the exact revision level of a product. Network driver software should not rely on this field to identify the product or its capabilities.

**Note:** This PBA number is not related to the MSI-X Pending Bit Array (PBA).

## 6.4.6 PXE Configuration Words (Word 0x30:3B)

PXE configuration is controlled by the following words.

### 6.4.6.1 Setup Options PCI Function 0 (Word 0x30)

The main setup options are stored in word 0x30. These options are those that can be changed by the user via the Control-S setup menu. Word 0x30 has the following format:

| Bit(s) | Name | Function                                                                                                                                                                                                                                                                                                                                                     |
|--------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

1. FCoE Boot ROM is N/A for the I350.

### 6.4.6.2 Configuration Customization Options PCI Function 0 (Word 0x31)

Word 0x31 of the EEPROM contains settings that can be programmed by an OEM or network administrator to customize the operation of the software. These settings cannot be changed from within the Control-S setup menu. The lower byte contains settings that would typically be configured by a network administrator using an external utility; these settings generally control which setup menu options are changeable. The upper byte is generally settings that would be used by an OEM to control the operation of the agent in a LOM environment, although there is nothing in the agent to prevent their use on a NIC implementation. The default value for this word is 4000h.

| Bit(s) | Name | Function                                                                                                                  |

| 11     | RETRY | Selects Continuous Retry operation.<br>If this bit is set, IBA will NOT transfer control back to the BIOS if it fails to boot due to a network error (such as failure to receive DHCP replies). Instead, it will restart the PXE boot process again. If this bit is set, the only way to cancel PXE boot is for the user to press ESC on the keyboard. Retry will not be attempted due to hardware conditions such as an invalid EEPROM checksum or failing to establish link. Default value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 10:8   | MODE  | Selects the agent's boot order setup mode.<br>This field changes the agent's default behavior in order to make it compatible with systems that do not completely support the BBS and PnP Expansion ROM standards. Valid values and their meanings are:<br>000b Normal behavior. The agent will attempt to detect BBS and PnP Expansion ROM support as it normally does.<br>001b Force Legacy mode. The agent will not attempt to detect BBS or PnP Expansion ROM supports in the BIOS and will assume the BIOS is not compliant. The user can change the BIOS boot order in the Setup Menu.<br>010b Force BBS mode. The agent will assume the BIOS is BBS-compliant, even though it may not be detected as such by the agent's detection code. The user can NOT change the BIOS boot order in the Setup Menu.<br>011b Force PnP Int18 mode. The agent will assume the BIOS allows boot order setup for PnP Expansion ROMs and will hook interrupt 18h (to inform the BIOS that the agent is a bootable device) in addition to registering as a BBS IPL device. The user can NOT change the BIOS boot order in the Setup Menu.<br>100b Force PnP Int19 mode. The agent will assume the BIOS allows boot order setup for PnP Expansion ROMs and will hook interrupt 19h (to inform the BIOS that the agent is a bootable device) in addition to registering as a BBS IPL device. The user can NOT change the BIOS boot order in the Setup Menu.<br>101b Reserved for future use. If specified, is treated as a value of 000b.<br>110b Reserved for future use. If specified, is treated as a value of 000b.<br>111b Reserved for future use. If specified, is treated as a value of 000b. |

| 1      | DTM   | Disable Title Message.<br>If this bit is set to 1, the title message displaying the version of the Boot Agent is suppressed; the Control-S message is also suppressed. This is for OEMs who do not wish the boot agent to display any messages at system boot. Default value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0      | DSM   | Disable Setup Menu.<br>If this bit is set to 1, the user is not allowed to invoke the setup menu by pressing Control-S. In this case, the EEPROM may only be changed via an external program. Default value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 6.4.6.3 PXE Version (Word 0x32)

Word 0x32 of the EEPROM is used to store the version of the boot agent that is stored in the flash image. When the Boot Agent loads, it can check this value to determine if any first-time configuration needs to be performed. The agent then updates this word with its version. Some diagnostic tools also read this word to report the version of the PXE Boot Agent in the flash.

The format of this word is:

| Bit(s)  | Name | Function                      |
|---------|------|-------------------------------|
| 15 - 12 | MAJ  | PXE Boot Agent Major Version. |
| 11 - 8  | MIN  | PXE Boot Agent Minor Version. |
| 7 - 0   | BLD  | PXE Boot Agent Build Number.  |

#### 6.4.6.4 Flash (Option ROM) Capabilities (Word 0x33)

Word 0x33 of the EEPROM is used to enumerate the boot technologies that have been programmed into the flash. This is updated by flash configuration tools and is not updated or read by IBA.

| Bit(s)  | Name  | Function                                                                                                                  |
|---------|-------|---------------------------------------------------------------------------------------------------------------------------|
| 15 - 14 | SIG   | Signature. Must be set to 01 to indicate that this word has been programmed by the agent or other configuration software. |
| 13 - 5  | RFU   | Reserved. Must be 0.                                                                                                      |
| 4       | ISCSI | iSCSI Boot is present in flash if set to 1.                                                                               |
| 3       | UEFI  | UEFI UNDI driver is present in flash if set to 1.                                                                         |
| 2       | RPL   | Reserved. Must be 0.                                                                                                      |
| 1       | UNDI  | PXE UNDI driver is present in flash if set to 1.                                                                          |
| 0       | BC    | PXE Base Code is present in flash if set to 1.                                                                            |

#### 6.4.6.5 Setup Options PCI Function 1 (Word 0x34)

This word is the same as word 0x30, but for function 1 of the device.

#### 6.4.6.6 Configuration Customization Options PCI Function 1 (Word 0x35)

This word is the same as word 0x31, but for function 1 of the device.

#### 6.4.6.7 Setup Options PCI Function 2 (Word 0x38)

This word is the same as word 0x30, but for function 2 of the device.

#### 6.4.6.8 Configuration Customization Options PCI Function 2 (Word 0x39)

This word is the same as word 0x31, but for function 2 of the device.

#### 6.4.6.9 Setup Options PCI Function 3 (Word 0x3A)

This word is the same as word 0x30, but for function 3 of the device.

### 6.4.6.10 Configuration Customization Options PCI Function 3 (Word 0x3B)

This word is the same as word 0x31, but for function 3 of the device.

### 6.4.6.11 PXE VLAN Configuration Pointer (0x003C)

| Bits | Name                           | Default | Description                                                                       |
|------|--------------------------------|---------|-----------------------------------------------------------------------------------|
| 15:0 | PXE VLAN Configuration Pointer | 0x0     | The pointer contains offset of the first Flash word of the PXE VLAN config block. |

### 6.4.6.12 PXE VLAN Configuration Section Summary Table

| Word Offset | Word Name            | Description                                                                                                                               |
|-------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0000      | VLAN Block Signature | ASCII 'V', 'L'.                                                                                                                           |
| 0x0001      | Version and Size     | Contains version and size of structure.                                                                                                   |
| 0x0002      | Port 0 VLAN Tag      | VLAN tag value for the first port of the I350. Contains PCP, CFI and VID fields. A value of 0 means no VLAN is configured for this port.  |
| 0x0003      | Port 1 VLAN Tag      | VLAN tag value for the second port of the I350. Contains PCP, CFI and VID fields. A value of 0 means no VLAN is configured for this port. |
| 0x0004      | Port 2 VLAN Tag      | VLAN tag value for the third port of the I350. Contains PCP, CFI and VID fields. A value of 0 means no VLAN is configured for this port.  |
| 0x0005      | Port 3 VLAN Tag      | VLAN tag value for the fourth port of the I350. Contains PCP, CFI and VID fields. A value of 0 means no VLAN is configured for this port. |

### 6.4.6.13 VLAN Block Signature - 0x0000

| Bits | Field Name           | Default | Description     |
|------|----------------------|---------|-----------------|
| 15:0 | VLAN Block Signature | 0x4C56  | ASCII 'V', 'L'. |

#### 6.4.6.14 Version and Size - 0x0001

| Bits | Field Name | Default | Description                                      |
|------|------------|---------|--------------------------------------------------|
| 15:8 | Size       |         | Total size in bytes of section.                  |
| 7:0  | Version    | 0x01    | Version of this structure. Should be set to 0x1. |

#### 6.4.6.15 Port 0 VLAN Tag - 0x0002

| Bits  | Field Name        | Default | Description       |
|-------|-------------------|---------|-------------------|
| 15:13 | Priority (0-7)    | 0x0     | Priority 0-7.     |
| 12    | Reserved          | 0x0     | Always 0.         |
| 11:0  | VLAN ID (1- 4095) | 0x0     | VLAN ID (1-4095). |

#### 6.4.6.16 Port 1 VLAN Tag - 0x0003

| Bits  | Field Name        | Default | Description       |
|-------|-------------------|---------|-------------------|
| 15:13 | Priority (0-7)    | 0x0     | Priority 0-7.     |
| 12    | Reserved          | 0x0     | Always 0.         |
| 11:0  | VLAN ID (1- 4095) | 0x0     | VLAN ID (1-4095). |

#### 6.4.6.17 Port 2 VLAN Tag - 0x0004

| Bits  | Field Name        | Default | Description       |
|-------|-------------------|---------|-------------------|
| 15:13 | Priority (0-7)    | 0x0     | Priority 0-7.     |
| 12    | Reserved          | 0x0     | Always 0.         |
| 11:0  | VLAN ID (1- 4095) | 0x0     | VLAN ID (1-4095). |

#### 6.4.6.18 Port 3 VLAN Tag - 0x0005

| Bits  | Field Name        | Default | Description       |
|-------|-------------------|---------|-------------------|
| 15:13 | Priority (0-7)    | 0x0     | Priority 0-7.     |
| 12    | Reserved          | 0x0     | Always 0.         |
| 11:0  | VLAN ID (1- 4095) | 0x0     | VLAN ID (1-4095). |

## 6.4.7 iSCSI Boot Words

### 6.4.7.1 iSCSI Option ROM Version (Word 0x36)

Word 0x36 is used to store the version of the iSCSI Boot option ROM if present. Values below 0x2000 are reserved and should not be used. This word may be modified by flash update utilities.

### 6.4.7.2 iSCSI boot Configuration Pointer (Word 0x3D)

| Bit  | Name          | Description                                                                                                                                                                                                                                                                                             |
|------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | iSCSI Address | iSCSI Configuration Block EEPROM Offset<br>Offset of iSCSI configuration block from the start of the EEPROM. If set to 0000h or FFFFh there is no EEPROM configuration data available for the iSCSI adapter. In this case configuration data must be provided by the BIOS through the SM CLP interface. |

### 6.4.7.3 iSCSI Module Structure

The table below defines the layout of the iSCSI boot configuration block stored in EEPROM. EEPROM word 0x3D described above stores the offset within the EEPROM of the configuration block. Software must first read word 0x3D to determine the offset of the configuration table before attempting to read or write the configuration block.

The strings defined below are stored in UTF-8 encoding and NULL terminated. All data words are stored in little-endian (Intel) byte order.

| Configuration Item        | Offset (Bytes) | Size in Bytes | Comments                                                                                                                                                                                                                                                                          |
|---------------------------|----------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Boot Signature            | 0x1:0x0        | 2             | 0x5369 ('i', 'S')                                                                                                                                                                                                                                                                 |
| Block Size                | 0x3:0x2        | 2             | The structure size is stored in this field and is set depending on the amount of free EEPROM space available. The total size of this structure, including variable length fields, must fit within this space.<br>0x0384 - single port<br>0x05E0 - dual port<br>0x0A98 - quad port |
| Structure Version         | 0x4            | 1             | Version of this structure. Should be set to one.                                                                                                                                                                                                                                  |

## 6.4.8 Alternate MAC address pointer (Word 0x37)

This word may point to a location in the EEPROM containing additional MAC addresses used by system management functions. If the additional MAC addresses are not supported, the word must be set to 0xFFFF. The structure of the alternate MAC address block can be found in [Table 6-14](#).

**Table 6-14 Alternate MAC Address Block**

| Word Offset | Description <sup>1</sup>                                      |
|-------------|---------------------------------------------------------------|
| 0x0...0x2   | Alternate MAC Address for LAN port assigned to PCI function 0 |
| 0x3...0x5   | Alternate MAC Address for LAN port assigned to PCI function 1 |
| 0x6...0x8   | Alternate MAC Address for LAN port assigned to PCI function 2 |
| 0x9...0xB   | Alternate MAC Address for LAN port assigned to PCI function 3 |

1. An alternate MAC Address value of 0xFFFF-FFFF-FFFF means that no alternate MAC address is present for the port.

## 6.4.9 Reserved/3rd Party External Thermal Sensor – (Word 0x3E)

| Bits | Name                    | Default | Description                                                                                                          |
|------|-------------------------|---------|----------------------------------------------------------------------------------------------------------------------|
| 15:0 | External Thermal Sensor | 0xFFFF  | Pointer to 3rd Party External Thermal Sensor Configuration block.<br>0x0000 and 0xFFFF indicates an invalid pointer. |

### 6.4.9.1 3rd Party External Thermal Sensor Configuration NVM Block

#### 6.4.9.1.1 External Thermal Sensor Configuration Block

| Word Offset | Description                            |
|-------------|----------------------------------------|
| 0x0         | ETS General configuration word         |
| 0x1         | Sensor Data – Sensor 1                 |
| ...         | (all sensor data)                      |
| N           | Sensor data – Sensor N (N is max of 4) |

#### 6.4.9.1.2 ETS General Configuration Word – Offset 0x0

This word contains general information about the external thermal sensor.

| Bits  | Name     | Description            |
|-------|----------|------------------------|
| 15:10 | Reserved | Reserved (default 0x0) |

|      |                     |                                                                                                                                                                                                      |

#### 6.4.10 Checksum Word (Offset 0x3F)

The checksum words (Offset 0x3F from start of Common, LAN 1, LAN 2 and LAN 3 sections) are used to ensure that the base EEPROM image is a valid image. The value of this word should be calculated such that after adding all the words (0x00:0x3E), including the checksum word itself, the sum should be 0xBABA. The initial value in the 16-bit summing register should be 0x0000 and the carry bit should be ignored after each addition.

**Note:** Hardware does not calculate the checksum word during EEPROM write; it must be calculated by software independently and included in the EEPROM write data. Hardware does not compute a checksum over words 0x00:0x3F during EEPROM reads in order to determine validity of the EEPROM image; this field is provided strictly for software verification of EEPROM validity. All hardware configurations based on word 0x00:0x3F content is based on the validity of the *Signature* field of the *EEPROM Sizing & Protected Fields* EEPROM word (*Signature* must be 01b).

### **6.4.11 Image Unique ID (Word 0x42, 0x43)**

These words contain a unique 32-bit ID for each image generated by Intel to enable tracking of images and comparison to the original image if testing a customer EEPROM image.

**NOTE:**      *This page intentionally left blank.*

§ §

## 7 Inline Functions

### 7.1 Receive Functionality

Typically, packet reception consists of recognizing the presence of a packet on the wire, performing address filtering, storing the packet in the receive data FIFO, transferring the data to one of the 8 receive queues in host memory, and updating the state of a receive descriptor.

A received packet goes through three stages of filtering as shown in [Figure 7-1](#). [Figure 7-1](#) describes a switch-like structure that is used in virtualization mode to route packets between the network port (top of drawing) and one or more virtual ports (bottom of figure), where each virtual port can be associated with a virtual machine, a VMM or any other software entity.

The first step in queue assignment is to verify that the packet is destined to the port. This is done by a set of L2 filters as described in [Section 7.1.3](#).

The second stage is specific to virtualization environments and defines the virtual ports (called pools) that are the targets for the Rx packet. A packet can be associated with any number of ports/pools using a selection process described in [Section 7.1.2.2](#).

**Figure 7-1** Stages in Packet Filtering

In the third stage, relevant only to non virtualized cases, a received packet that successfully passed the Rx filters is associated with one or more receive descriptor queues as described in [Section 7.1.1](#). In the virtualized case, the queue is fixed only according to the pool.

## 7.1.1 L2 Packet Filtering

The receive packet filtering role is to determine which of the incoming packets are allowed to pass to the local system and which of the incoming packets should be dropped since they are not targeted to the local system. Received packets can be destined to the host, to a manageability controller (BMC), or to both. This section describes how host filtering is done, and the interaction with management filtering.

As shown in [Figure 7-2](#), host filtering has three stages:

1. Packets are filtered by L2 filters (MAC address, unicast/multicast/broadcast). See [Section 7.1.1.1](#) for details.
2. Packets are then filtered by VLAN if a VLAN tag is present. See [Section 7.1.1.2](#) for details.
3. Packets are filtered by the manageability filters (port, IP, flex, other). See [Section 10.3.3](#) for details.

A packet is not forwarded to the host if any of the following takes place:

1. The packet does not pass MAC address filters as described later in this section.
2. The packet does not pass VLAN filtering as described later in this section.
3. The packet passes manageability filtering and then the manageability filters determine that the packet should be sent only to the BMC (see [Section 10.3](#) and the *MNGONLY* register).

A packet that passes receive filtering as previously described might still be dropped due to other reasons. Normally, only good packets are received. These are defined as those packets with no Under Size Error, Over Size Error (see [Section 7.1.1.4](#)), Packet Error, Length Error and CRC Error are detected. However, if the *store-bad-packet* bit is set (*RCTL.SBP*), then bad packets that pass the filter function are stored in host memory. Packet errors are indicated by error bits in the receive descriptor (*RDESC.ERRORS*). It is possible to receive all packets, regardless of whether they are bad, by setting the promiscuous enabled (Unicast and Multicast) and the *store-bad-packet* bits in the *RCTL* register.

If there is insufficient space in the receive FIFO, hardware drops the packet and indicates the missed packet in the appropriate statistics registers.

When the packet is routed to a queue with the *SRRCTL.Drop\_En* bit set to 1, receive packets are dropped when insufficient receive descriptors exist to write the packet into system memory.

**Note:** CRC errors before the SFD are ignored. Any packet must have a valid SFD in order to be recognized by the I350 (even bad packets).

**Figure 7-2 Receive Filtering Flow Chart**

### 7.1.1.1 MAC Address Filtering

Figure 7-3 shows the MAC address filtering. A packet passes successfully through the MAC address filtering if any of the following conditions are met:

1. It is a unicast packet and promiscuous unicast filtering is enabled.
2. It is a multicast packet and promiscuous multicast filtering is enabled.
3. It is a unicast packet and it matches one of the unicast MAC filters.
4. It is a multicast packet and it matches one of the multicast filters.
5. It is a broadcast packet and Broadcast Accept Mode (*RCTL.BAM*) is enabled.

**Figure 7-3 Host MAC Address Receive Filtering Flow Chart**

### 7.1.1.1.1 Unicast Filter

The entire MAC address is checked against the 32 host unicast addresses. The 32 host unicast addresses are controlled by the host interface (the BMC must not change them). The other 4 addresses are dedicated to management functions and are only accessed by the BMC. The destination address of incoming packet must exactly match one of the pre-configured host address filters. These addresses can be unicast or multicast. Those filters are configured through *RAL*, and *RAH* registers.

**Promiscuous Unicast** — Receive all unicasts. Promiscuous unicast mode in the *RCTL* register can be set/cleared only through the host interface (not by the BMC). This mode is usually used when I350 is used as a sniffer.

Unicast Hash Table — Destination address matching the Unicast Hash Table (*UTA*). In this case if the packet only matches to the Unicast Hash Table (*UTA*) the *PIF* bit in the receive descriptor is set to 1b (See [Section 7.1.4.1](#)) and Software needs to examine the packet to verify that it's destined to the station.

#### 7.1.1.1.2 Multicast Filter (Inexact)

A 12-bit portion of incoming packet multicast address must exactly match Multicast Filter Address (*MFA*) in order to pass multicast filtering. Which 12 bits out of 48 bits of the destination address are used can be selected by the *MO* field of *RCTL* ([Section 8.10.1](#)). The 12 bits extracted from the Multicast Destination address are used as an address for a bit in the Multicast Table Array (*MTA*). If the value of the bit selected in the *MTA* table is 1b, the packet is sent to the Host (See [Section 8.10.15](#)). These entries can be configured only by the host interface and cannot be controlled by the BMC. Packets received according to this mode have the *PIF* bit in the descriptor set to indicate imperfect filtering that should be validated by the software device driver.

Promiscuous Multicast — Receive all multicast. Promiscuous multicast mode can be set/cleared in the *RCTL* register only through the host interface (not by the BMC) and it is usually used when the I350 is used as a sniffer.

**Note:** When the promiscuous bit is set and a multicast packet is received, the *PIF* bit of the packet status is not set.

#### 7.1.1.2 VLAN Filtering

A receive packet that successfully passed MAC address filtering is then subjected to VLAN header filtering.

1. If the packet does not have a VLAN header, it passes to the next filtering stage.

**Note:** If external VLAN is enabled (*CTRL\_EXT.EXT\_VLAN* is set), it is assumed that the first VLAN tag is an external VLAN and it is skipped. All next stages refer to the second VLAN.

2. If VLAN filtering is disabled (*RCTL.VFE* bit is cleared), the packet is forwarded to the next filtering stage.
3. If the packet has a VLAN header, and it matches an enabled host VLAN filter (relevant bit in *VFTA* table is set), the packet is forwarded to the next filtering stage.
4. Otherwise, the packet is dropped.

[Figure 7-4](#) shows the VLAN filtering flow.

**Figure 7-4** VLAN Filtering

### 7.1.1.3 Manageability Filtering

Manageability filtering is described in [Section 10.3](#).

[Figure 7-5](#) shows the manageability portion of the packet filtering and it is brought here to make the receive packet filtering functionality description complete.

**Note:** The manageability engine might decide to block part of the received packets from also being sent to the Host, according to the external BMC instructions and the EEPROM settings.

**Figure 7-5 Manageability Filtering**

### 7.1.1.4 Size Filtering

A packet is defined as undersize if it is smaller than 64 bytes.

A packet is defined as oversize in the following conditions:

- The *RCTL.LPE* bit cleared and one of the following conditions is met:
  - The packet is bigger than 1518 bytes and there are no VLAN tags in the packet.
  - The packet is bigger than 1522 bytes and there is one VLAN tag in the packet.
  - The packet is bigger than 1526 bytes and there are two VLAN tags in the packet.
- The *RCTL.LPE* bit is set to 1b and the packet is bigger than *RLPML.RLPML* bytes.

**Note:** Maximum supported received-packet size is 9.5 KB (9728 bytes).

**Note:** In VMDq mode, a packet is defined as oversized only if it is bigger than the *VOMLR.RLPML* value for all the VM/VFs that were supposed to receive the packet.

## 7.1.2 Receive Queues Assignment

The following filter mechanisms determines the destination of a receive packet. These are described briefly in this section and in full details in separate sections:

- **Virtualization** — In a virtualized environment, DMA resources are shared between more than one software entity (operating system and/or software device driver). This is done by allocating receive descriptor queues/pools to virtual partitions (VMM or VMs). Virtualization assigns to each received packet one or more pool indices. Packets are routed to a pool based on their pool index and other considerations. See [Section 7.1.2.2](#) for details on routing for virtualization.
- **RSS** — Receive Side Scaling distributes packet processing between several processor cores by assigning packets into different descriptor queues. RSS assigns to each received packet an RSS index. Packets are routed to a queue out of a set of Rx queues based on their RSS index and other considerations. See [Section 7.1.2.8](#) for details on RSS.
- **L2 Ethertype filters** — These filters identify packets by their L2 Ether type and assign them to receive queues. Examples of possible uses are LLDP packets and 802.1X packets. See [Section 7.1.2.4](#) for mode details. The I350 incorporates 8 Ether-type filters per port.
- **2-tuple filters** — These filters identify packets with specific TCP/UDP destination port and/or L4 protocol. Each filter consists of a 2-tuple (protocol and destination TCP/UDP port) and routes packets into one of the Rx queues. The I350 has 8 such filters per port. See [Section 7.1.2.5](#) for details.
- **TCP SYN filters** — The I350 might route TCP packets with their SYN flag set into a separate queue. SYN packets are often used in SYN attacks to load the system with numerous requests for new connections. By filtering such packets to a separate queue, security software can monitor and act on SYN attacks. The I350 has one such filter per port. See [Section 7.1.2.7](#) for more details.
- **Flex Filters** - These filters can be either used as WoL filters when the I350 is in D3 state or for queueing in normal operating mode (D0 state). Filters enable queueing according to a match of any 128 Byte sequence at the beginning of a packet. Each one of the 128 bytes can be either compared or masked using a dedicated mask field. The I350 has 8 such filters per port. See [Section 7.1.2.6](#) for details.

A received packet is allocated to a queue as described in the following sections.

The tables below describe allocation of queues in each of the modes.

**Table 7-1 Queue Allocation<sup>1</sup>**

| Virtualization | RSS      | Queue allocation                                                                                                                            |
|----------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Disabled       | Disabled | One default queue (MRQC.DEF_Q)                                                                                                              |
|                | Enabled  | Up to 8 queues by RSS.                                                                                                                      |
| Enabled        | Disabled | One queue per VM (queues 0-7 for VM 0-7).                                                                                                   |
|                | Enabled  | Two queues per VM (queues 0, 8; 1, 9; 2, 10; 3, 11; 4, 12; 5, 13; 6, 14; 7, 15 for VM 0-7, respectively). Spread between the queues by RSS. |

**Table 7-1 Queue Allocation<sup>1</sup>**

| Virtualization | RSS      | Queue allocation                                                                                                      |
|----------------|----------|-----------------------------------------------------------------------------------------------------------------------|
| Disabled       | Disabled | One queue per TC (Queue 0 and 8).                                                                                     |
|                | Enabled  | Eight queues per TC (queues 0-7 for TC0 and queues 8-15 for TC1). Spread between the queues by RSS.                   |
| Enabled        | Disabled | One queue per TC per VM (Queues 0, 8; 1, 9; 2, 10; 3, 11; 4, 12; 5, 13; 6, 14; 7, 15 for VM 0-7/TC 0,1 respectively). |
|                | Enabled  | Not available                                                                                                         |

1. On top of this allocation, the special filters can override the queueing decision.

### 7.1.2.1 Queuing in a Non-Virtualized Environment

When the *MRQC.Multiple Receive Queues Enable* field equals 010b (Multiple receive queues as defined by filters and RSS for 8 queues) or 000b (Multiple receive queues as defined by filters (2-tuple filters, L2 Ether-type filters, SYN filter and Flex Filters), the received packet is assigned to a queue in the following manner (Each filter identifies one of 8 receive queues):

1. Queue by L2 Ether-type filters (if a match)
2. If RFCTL.SYNQFP is 0b (2-tuple filter and Flex filter have priority), then:
  - a. Queue by Flex filter (if a match)
  - b. Queue by 2-tuple filter
  - c. Queue by SYN filter (if a match)
3. If RFCTL.SYNQFP is 1b (SYN filter has priority), then:
  - a. Queue by SYN filter (if a match)
  - b. Queue by Flex filter (if a match)
  - c. Queue by 2-tuple filter (if a match)
4. Queue by RSS (if RSS enabled) - Identifies one of 1 x 8 queues through the RSS index. The following modes are supported:
  - No RSS — The default queue as defined in *MRQC.DEF\_Q* is used for packets that do not meet any of the previous conditions.
  - RSS only — A set of 8 queues is allocated for RSS. The queue is identified through the RSS index. Note that it is possible to use a subset of the 8 queues.

**Note:** No RSS here mean either that RSS is disabled (*MRQC.Multiple Receive Queues Enable* field equals 000b) or that the packet did not match any of the RSS filters.

Figure 7-6 describes the non virtualized receive queue assignment flow.

### 7.1.2.2 Receive Queuing in a Virtualized Environment

In VMDq mode, system software allocates the pools to the VMM, an IOVM, or to VMs. When the *MRQC.Multiple Receive Queues Enable* field equals 011b (Multiple receive queues as defined by VMDq), the received packets are allocated to the 8 receive queues/pools in the following manner:

Incoming packets are associated with pools/queues based on their L2 characteristics as described in [Section 7.8.3](#).

Figure 7-6 describes the generic virtualized receive queue assignment flow.

**Figure 7-6 Receive Queuing Flow (Virtualization)**

### 7.1.2.3 Queue Configuration Registers

Configuration registers (CSRs) that control queue operation are replicated per queue (total of 8 copies of each register per port). Each of the replicated registers correspond to a queue such that the queue index equals the serial number of the register (such as register 0 corresponds to queue 0, etc.). Registers included in this category are:

- *RDBAL* and *RDBAH* — Rx Descriptor Base
- *RDLEN* — RX Descriptor Length
- *RDH* — RX Descriptor Head
- *RDT* — RX Descriptor Tail
- *RXDCTL* — Receive Descriptor Control
- *RXCTL* — Rx DCA Control
- *SRRCTL* — Split and Replication Receive Control

CSRs that define the functionality of descriptor queues are replicated per VM pool to allow for a separate configuration in a virtualized environment (total of 8 copies of each register). Each of the replicated registers correspond to a set of queues in the same VM pool. Registers included in this category are:

- *PSRTYPE* — Packet Split Receive type

### 7.1.2.4 L2 Ether-Type Filters

These filters identify packets by L2 Ether-type and assign them to a receive queue. The following usages have been identified:

- IEEE 802.1X packets — Extensible Authentication Protocol over LAN (EAPOL).
- Time sync packets (such as IEEE 1588) — Identifies Sync or Delay\_Req packets
- IEEE802.1AB LLDP (Link Layer Discovery Protocol) packets.

The I350 incorporates 8 Ether-type filters.

The *Packet Type* field in the Rx descriptor captures the filter number that matched the L2 Ether-type. See [Section 7.1.4.2](#) for decoding of the *Packet Type* field.

The Ether-type filters are configured via the ETQF register as follows:

- The *EType* field contains the 16-bit Ether-type compared against all L2 type fields in the Rx packet.
- The *Filter Enable* bit enables identification of Rx packets by Ether-type according to this filter. If this bit is cleared, the filter is ignored for all purposes.
- The *Rx Queue* field contains the absolute destination queue for the packet.
- The *1588 Time Stamp* field indicates that the packet should be time stamped according to the IEEE 1588 specification.
- The *Queue Enable* field enables forwarding Rx packets based on the Ether-type defined in this register.

**Note:** Software should not assign the same Ether-type value to different ETQF filters with different *Rx Queue* assignments.

Special considerations for Virtualization modes:

- Packets that match an Ether-type filter are diverted from their original pool (the pool identified by the L2 filters) to the pool used as the pool to which the queue in the *Queue* field belongs. In other words, The L2 filters are ignored in determining the pool for such packets.
- The same applies for multi-cast packets. A single copy is posted to the pool defined by the filter.
- Mirroring rules:
  - If a pool is being mirrored, the pool to which the queue in the *Queue* field belongs to is used to determine if a packet that matches the filter should be mirrored.
  - The queue inside the pool (indicated by the *Queue* field) is used for both the original pool and the mirroring pool.

### 7.1.2.5 2-Tuple Filters

These filters identify specific packets destined to a certain TCP/UDP port and implement a specific protocol. Each filter consists of a 2-tuple (protocol and destination TCP/UDP port) and forwards packets into one of the receive queues.

The I350 incorporates 8 such filters.

The 2-tuple filters are configured via the *TTQF* (See [Section 8.11.4](#)), *IMIR* (See [Section 8.11.1](#)) and *IMIR\_EXT* (See [Section 8.11.2](#)) registers as follows (per filter):

- Protocol — Identifies the IP protocol, part of the 2-tuple queue filters. Enabled by a bit in the *TTQF.Mask* field.
- Destination port — Identifies the TCP/UDP destination port, part of the 2-tuple queue filters. Enabled by the *IMIR.PORT\_BP* bit.
- Size threshold (*IMIREXT.Size\_Thresh*) — Identifies the length of the packet that should trigger the filter. This is the length as received by the host, not including any part of the packet removed by hardware. Enabled by the *IMIREXT.Size\_BP* field.
- Control Bits — Identify TCP flags that might be part of the filtering process. Enabled by the *IMIREXT.CtrlBit\_BP* field.

**Note:** When using the Control Bits filters, the Protocol filter must be enabled and set to TCP.

- Rx queue — Determines the Rx queue for packets that match this filter:
  - In a non-virtualized configuration, the *TTQF.Rx Queue* field contains the queue serial number.
  - In the virtualized configuration, the *FTQF.Rx Queue* field contains the queue serial number within the set of queues of the VF associated (via the *FTQF.VF* field) with this filter. In this case, the packet is sent to all VFs in the VF index list (see [Section 7.1.2.2](#) for details) in the queue defined in the filter.
- Queue enable — Enables forwarding a packet that uses this filter to the queue defined in the *TTQF.Rx Queue* field.
- VF — Identifies the VF associated with this filter by its VF index (virtualization modes only). A packet must match the VF filters (such as MAC address) and the 5-tuple filter for this filter to apply.

**Note:** The above field should not be set to match a mirror port (such as a port that receives promiscuous traffic), as it influences the queuing of packets sent to mirrored port.

- VF Mask — Determines if the *VF* field participates in the 5-tuple match or is ignored:
  - Must be set to 1b in non-virtualized case
  - In a virtualized configuration:
    - When set to 0b, only unicast packets that match the *VF* field are candidates for this filter.
    - When set to 1b, unicast, multicast, and broadcast packets might all match with the 5-tuple filter. VF association is not checked. The *Rx Queue* field defines a queue for each VF.
- Mask — A 1-bit field that masks the L4 protocol check. The filter is a logical AND of the non-masked 2-tuple fields. If all 2-tuple fields are masked, the filter is not used for queue forwarding.

#### Notes:

- If more than one 2-tuple filter with the same priority is matched by the packet, the first filter (lowest ordinal number) is used in order to define the queue destination of this packet.
- The immediate interrupt and 1588 actions are defined by the OR of all the matching filters.

## 7.1.2.6 Flex Filters

The I350 supports a total of 8 flexible filters. Each filter can be configured to recognize any arbitrary pattern within the first 128 bytes of the packet. To configure the flexible filters, software programs the mask values (required values and the minimum packet length), into the Flexible Host Filter Table (*FHFT*)

and *FHFT\_EXT*, See [Section 8.20.11](#) and [Section 8.20.12](#)). These 8 flexible filters can be used as for wake-up or proxying when in D3 state or for queueing when in D0 state. Software must enable the filters in the *Wake Up Filter Control* (*WUFC* See [Section 8.20.2](#)) register or *Proxying Filter Control* (*PROXYFC* see [Section 8.20.6](#)) for operation in D3 low power mode or in the *WUFC* register in D0 mode. In D0 mode these filters enable forwarding of packets that match up to 128 Bytes defined in the filter to one of the receive queues. In D3 mode these filters can be used for Wake-on-Lan as described in [Section 5.6.3.1.8](#) or proxying as described in [Section 5.7](#).

Once enabled, the flexible filters scan incoming packets for a match. If the filter encounters any byte in the packet where the mask bit is one and the byte doesn't match the value programmed in the Flexible Host Filter Table (*FHFT* or *FHFT\_EXT*), then the filter fails that packet. If the filter reaches the required length without failing the packet, it forwards the packet to the appropriate receive queue. It ignores any mask bits set to one beyond the required length (defined in the Length field in the *FHFT* or *FHFT\_EXT* registers).

**Note:** The flex filters are temporarily disabled when read from or written to by the host. Any packet received during a read or write operation is dropped. Filter operation resumes once the read or write access completes.

The flex filters are configured in D0 state via the *WUFC*, *FHFT* and *FHFT\_EXT* registers as follows (per filter):

- Byte Sequence to be compared - Program 128 Byte sequence, mask bits and *Length* field in *FHFT* and *FHFT\_EXT* registers.
- Filter Priority - Program filter priority in queueing field in *FHFT* and *FHFT\_EXT* registers.
- Receive queue - Program receive queue to forward packet in queueing field in *FHFT* and *FHFT\_EXT* registers.
- Filter actions - Program immediate interrupt requirement in queueing field in *FHFT* and *FHFT\_EXT* registers.
- Filter enable - Set *WUFC.FLEX\_HQ* bit to 1 to enable flex filter operation in D0 state. Set appropriate *WUFC.FLX[n]* bit to 1 to enable specific flex filter.

Before entering D3 state software device driver programs the *FHFT* and *FHFT\_EXT* filters for appropriate wake events and enables relevant filters by setting the *WUFC.FLX[n]* bit to 1 or the *PROXYFC.FLX[n]* bit to 1. Following move to D0 state the software device driver programs the *FHFT* and *FHFT\_EXT* filters for appropriate queueing decisions and enables the relevant filters by setting the *WUFC.FLX[n]* bit to 1 and the *WUFC.FLEX\_HQ* bit to 1.

**Notes:** If more than one flex filter with the same priority is matched by the packet, the first filter (lowest address) is used in order to define the queue destination of this packet.

The immediate interrupt action is defined by the OR of all the matching filters.

These filters are not available for VM to VM traffic forwarding.

### 7.1.2.7 SYN Packet Filters

The I350 might forward TCP packets whose SYN flag is set into a separate queue. SYN packets are often used in SYN attacks to load the system with numerous requests for new connections. By filtering such packets to a separate queue, security software can monitor and act on SYN attacks.

SYN filters are configured via the SYNQF registers as follows:

- Queue En — Enables forwarding of SYN packets to a specific queue.
- Rx Queue field — Contains the destination queue for the packet.

This filter is not to be used in a virtualized environment.

### 7.1.2.8 Receive-Side Scaling (RSS)

RSS is a mechanism to distribute received packets into several descriptor queues. Software then assigns each queue to a different processor, sharing the load of packet processing among several processors.

The I350 uses RSS as one ingredient in its packet assignment policy (the others are the various filters and virtualization). The RSS output is a RSS index. The I350's global assignment uses these bits (or only some of the LSB bits) as part of the queue number.

RSS is enabled in the *MRQC* register. The *RSS Status* field in the descriptor write-back is enabled when the *RXCSUM.PCSD* bit is set (fragment checksum is disabled). RSS is therefore mutually exclusive with UDP fragmentation. Also, support for RSS is not provided when legacy receive descriptor format is used.

When RSS is enabled, the I350 provides software with the following information as required by Microsoft\* RSS specification or for device driver assistance:

- A Dword result of the Microsoft\* RSS hash function, to be used by the stack for flow classification, is written into the receive packet descriptor (required by Microsoft\* RSS).
- A 4-bit *RSS Type* field conveys the hash function used for the specific packet (required by Microsoft\* RSS).

Figure 7-7 shows the process of computing an RSS output:

1. The receive packet is parsed into the header fields used by the hash operation (such as IP addresses, TCP port, etc.).
2. A hash calculation is performed. The I350 supports a single hash function, as defined by Microsoft\* RSS. The I350 does not indicate to the software device driver which hash function is used. The 32-bit result is fed into the packet receive descriptor.
3. The seven LSB bits of the hash result are used as an index into a 128-entry indirection table. Each entry provides a 3-bit RSS output index.

When RSS is disabled, packets are assigned an RSS output index = zero. System software might enable or disable RSS at any time. While disabled, system software might update the contents of any of the RSS-related registers.

When multiple requests queues are enabled in RSS mode, un-decodable packets are assigned an RSS output index = zero. The 32-bit tag (normally a result of the hash function) equals zero.

**Figure 7-7 RSS Block Diagram**

### 7.1.2.8.1 RSS Hash Function

Section 7.1.2.8.1 provides a verification suite used to validate that the hash function is computed according to Microsoft\* nomenclature.

The I350 hash function follows Microsoft\* definition. A single hash function is defined with several variations for the following cases:

- **TcpIPv4** — The I350 parses the packet to identify an IPv4 packet containing a TCP segment per the criteria described later in this section. If the packet is not an IPv4 packet containing a TCP segment, RSS is not done for the packet.
- **IPv4** — The I350 parses the packet to identify an IPv4 packet. If the packet is not an IPv4 packet, RSS is not done for the packet.
- **TcpIPv6** — The I350 parses the packet to identify an IPv6 packet containing a TCP segment per the criteria described later in this section. If the packet is not an IPv6 packet containing a TCP segment, RSS is not done for the packet.

- **TcpIPv6Ex** — The I350 parses the packet to identify an IPv6 packet containing a TCP segment with extensions per the criteria described later in this section. If the packet is not an IPv6 packet containing a TCP segment, RSS is not done for the packet. Extension headers should be parsed for a *Home-Address-Option* field (for source address) or the *Routing-Header-Type-2* field (for destination address).
- **IPv6Ex** — The I350 parses the packet to identify an IPv6 packet. Extension headers should be parsed for a *Home-Address-Option* field (for source address) or the *Routing-Header-Type-2* field (for destination address). Note that the packet is not required to contain any of these extension headers to be hashed by this function. In this case, the IPv6 hash is used. If the packet is not an IPv6 packet, RSS is not done for the packet.
- **IPv6** — The I350 parses the packet to identify an IPv6 packet. If the packet is not an IPv6 packet, receive-side-scaling is not done for the packet.

The following additional cases are not part of the Microsoft\* RSS specification:

- **UdpIPv4** — The I350 parses the packet to identify a packet with UDP over IPv4.
- **UdpIPv6** — The I350 parses the packet to identify a packet with UDP over IPv6.
- **UdpIPv6Ex** — The I350 parses the packet to identify a packet with UDP over IPv6 with extensions.

A packet is identified as containing a TCP segment if all of the following conditions are met:

- The transport layer protocol is TCP (not UDP, ICMP, IGMP, etc.).
- The TCP segment can be parsed (such as IP options can be parsed, packet not encrypted).
- The packet is not fragmented (even if the fragment contains a complete TCP header).

Bits[31:16] of the Multiple Receive Queues Command (*MRQC*) register enable each of the above hash function variations (several can be set at a given time). If several functions are enabled at the same time, priority is defined as follows (skip functions that are not enabled):

IPv4 packet:

1. Try using the **TcpIPv4** function.
2. Try using **IPV4\_UDP** function.
3. Try using the **IPv4** function.

IPv6 packet:

1. If **TcpIPv6Ex** is enabled, try using the **TcpIPv6Ex** function; else if **TcpIPv6** is enabled try using the **TcpIPv6** function.
2. If **UdpIPv6Ex** is enabled, try using **UdpIPv6Ex** function; else if **UdpIPv6** is enabled try using **UdpIPv6** function.
3. If **IPv6Ex** is enabled, try using the **IPv6Ex** function, else if **IPv6** is enabled, try using the **IPv6** function.

The following combinations are currently supported:

- Any combination of **IPv4**, **TcpIPv4**, and **UdpIPv4**.
- And/or.
- Any combination of either **IPv6**, **TcpIPv6**, and **UdpIPv6** or **IPv6Ex**, **TcpIPv6Ex**, and **UdpIPv6Ex**.

When a packet cannot be parsed by the previously mentioned rules, it is assigned an RSS output index = zero. The 32-bit tag (normally a result of the hash function) equals zero.

The 32-bit result of the hash computation is written into the packet descriptor and also provides an index into the indirection table.

The following notation is used to describe the hash functions:

- Ordering is little endian in both bytes and bits. For example, the IP address 161.142.100.80 translates into 0xa18e6450 in the signature.
- A  $\wedge$  denotes bit-wise XOR operation of same-width vectors.
- @x-y denotes bytes x through y (including both of them) of the incoming packet, where byte 0 is the first byte of the IP header. In other words, it is considered that all byte-offsets as offsets into a packet where the framing layer header has been stripped out. Therefore, the source IPv4 address is referred to as @12-15, while the destination v4 address is referred to as @16-19.
- @x-y, @v-w denotes concatenation of bytes x-y, followed by bytes v-w, preserving the order in which they occurred in the packet.

All hash function variations (IPv4 and IPv6) follow the same general structure. Specific details for each variation are described in the following section. The hash uses a random secret key length of 320 bits (40 bytes); the key is typically supplied through the RSS Random Key Register (RSSRK).

The algorithm works by examining each bit of the hash input from left to right. Intel's nomenclature defines left and right for a byte-array as follows: Given an array K with k bytes, Intel's nomenclature assumes that the array is laid out as shown:

K[0] K[1] K[2] ... K[k-1]

K[0] is the left-most byte, and the MSB of K[0] is the left-most bit. K[k-1] is the right-most byte, and the LSB of K[k-1] is the right-most bit.

ComputeHash(input[], N)

For hash-input input[] of length N bytes (8N bits) and a random secret key K of 320 bits  
Result = 0;

```
For each bit b in input[] {
  if (b == 1) then Result ^= (left-most 32 bits of K);
  shift K left 1 bit position;
}
return Result;
```

The following four pseudo-code examples are intended to help clarify exactly how the hash is to be performed in four cases, IPv4 with and without ability to parse the TCP header and IPv6 with and without a TCP header.

#### 7.1.2.8.1.1 Hash for IPv4 with TCP

Concatenate SourceAddress, DestinationAddress, SourcePort, DestinationPort into one single byte-array, preserving the order in which they occurred in the packet:

Input[12] = @12-15, @16-19, @20-21, @22-23.

Result = ComputeHash(Input, 12);

#### 7.1.2.8.1.2 Hash for IPv4 with UDP

Concatenate SourceAddress, DestinationAddress, SourcePort, DestinationPort into one single byte-array, preserving the order in which they occurred in the packet:

Input[12] = @12-15, @16-19, @20-21, @22-23.

Result = ComputeHash(Input, 12);

#### 7.1.2.8.1.3 Hash for IPv4 without TCP

Concatenate SourceAddress and DestinationAddress into one single byte-array

Input[8] = @12-15, @16-19

Result = ComputeHash(Input, 8)

#### 7.1.2.8.1.4 Hash for IPv6 with TCP

Similar to above:

Input[36] = @8-23, @24-39, @40-41, @42-43  
Result = ComputeHash(Input, 36)

#### 7.1.2.8.1.5 Hash for IPv6 with UDP

Similar to above:

Input[36] = @8-23, @24-39, @40-41, @42-43  
Result = ComputeHash(Input, 36)

#### 7.1.2.8.1.6 Hash for IPv6 without TCP

Input[32] = @8-23, @24-39  
Result = ComputeHash(Input, 32)

#### 7.1.2.8.2 Indirection Table

The *RETA* indirection table is a 128-entry structure, indexed by the seven LSB bits of the hash function output. Each entry of the table contains the following:

- Bits [2:0] - RSS index

**Note:** In RSS only mode, all 3 bits are used. In VMDq mode RSS is not supported.

System software might update the indirection table during run time. Such updates of the table are not synchronized with the arrival time of received packets. Therefore, it is not guaranteed that a table update takes effect on a specific packet boundary.

#### 7.1.2.8.3 RSS Verification Suite

Assume that the random key byte-stream is:

0x6d, 0x5a, 0x56, 0xda, 0x25, 0x5b, 0x0e, 0xc2,  
0x41, 0x67, 0x25, 0x3d, 0x43, 0xa3, 0x8f, 0xb0,  
0xd0, 0xca, 0x2b, 0xcb, 0xae, 0x7b, 0x30, 0xb4,  
0x77, 0xcb, 0x2d, 0xa3, 0x80, 0x30, 0xf2, 0x0c,  
0x6a, 0x42, 0xb7, 0x3b, 0xbe, 0xac, 0x01, 0xfa

### 7.1.2.8.3.1 IPv4

**Table 7-2 IPv4**

| Destination Address/Port | Source Address/Port  | IPv4 Only  | IPv4 With TCP |
|--------------------------|----------------------|------------|---------------|
| 161.142.100.80:1766      | 66.9.149.187:2794    | 0x323e8fc2 | 0x51cccc178   |
| 65.69.140.83:4739        | 199.92.111.2:14230   | 0xd718262a | 0xc626b0ea    |
| 12.22.207.184:38024      | 24.19.198.95:12898   | 0xd2d0a5de | 0x5c2b394a    |
| 209.142.163.6:2217       | 38.27.205.30:48228   | 0x82989176 | 0xafc7327f    |
| 202.188.127.2:1303       | 153.39.163.191:44251 | 0x5d1809c5 | 0x10e828a2    |

### 7.1.2.8.3.2 IPv6

The IPv6 address tuples are only for verification purposes and might not make sense as a tuple.

**Table 7-3 IPv6**

| Destination Address/Port         | Source Address/Port                         | IPv6 Only  | IPv6 With TCP |
|----------------------------------|---------------------------------------------|------------|---------------|
| 3ffe:2501:200:3::1 (1766)        | 3ffe:2501:200:1fff::7 (2794)                | 0x2cc18cd5 | 0x40207d3d    |
| ff02::1 (4739)                   | 3ffe:501:8::260:97ff:fe40:efab (14230)      | 0x0f0c461c | 0xdd51bbf     |
| fe80::200:f8ff:fe21:67cf (38024) | 3ffe:1900:4545:3:200:f8ff:fe21:67cf (44251) | 0x4b61e985 | 0x02d1feef    |

### 7.1.2.8.4 Association Through MAC Address

Each of the 32 MAC address filters can be associated with a VF/VM. The *POOLSEL* field in the Receive Address High (*RAH*) register determines the target VM. Packets that do not match any of the MAC filters (such as promiscuous) are assigned with the default VM as defined in the *VT\_CTL.DEF\_PL* field.

Software can program different values to the MAC filters (any bits in *RAH* or *RAL*) at any time. The I350 would respond to the change on a packet boundary but does not guarantee the change to take place at some precise time.

## 7.1.3 Receive Data Storage

### 7.1.3.1 Host Buffers

Each descriptor points to a one or more memory buffers that are designated by the software device driver to store packet data.

The size of the buffer can be set using either the generic *RCTL.BSIZE* field, or the per queue *SRRCTL[n].BSIZEPACKET* field.

If *SRRCTL[n].BSIZEPACKET* is set to zero for any queue, the buffer size defined by *RCTL.BSIZE* is used. Otherwise, the buffer size defined by *SRRCTL[n].BSIZEPACKET* is used.

If the receive buffer size is selected by bit settings in the Receive Control (*RCTL.BSIZE*) buffer sizes of 256, 512, 1024, and 2048 bytes are supported.

If the receive buffer size is selected by *SRRCTL[n].BSIZEPACKET*, buffer sizes of 1Kbytes to 127 KBytes are supported with a resolution of 1KByte.

In addition, for advanced descriptor usage the *SRRCTL.BSIZEHEADER* field is used to define the size of the buffers allocated to headers. Header Buffer sizes of 64 bytes to 2048 bytes with a resolution of 64 bytes are supported.

The I350 places no alignment restrictions on receive memory buffer addresses. This is desirable in situations where the receive buffer was allocated by higher layers in the networking software stack, as these higher layers might have no knowledge of a specific device's buffer alignment requirements.

**Note:** When the *No-Snoop Enable* bit is used in advanced descriptors, the buffer address is 16-bit (2-byte) aligned.

### 7.1.3.2 On-Chip Receive Buffers

The I350 allocates by default a 36 KB on-chip packet buffer per port. The buffer can be used to store packets until they are forwarded to the host. The I350 utilizes a single common ram structure for the on-chip receive buffers allocated to the various ports. If a port is disabled, so that it can't be accessed by host and management, by either:

1. Pin assertion (LAN0\_DIS\_N, LAN1\_DIS\_N, LAN2\_DIS\_N, LAN3\_DIS\_N for port 0 to 3 respectively) and setting the EEPROM bit *PHY\_in\_LAN\_disable* in the "Software Defined Pins Control" word to 1 for the relevant port.
2. Setting EEPROM bit *LAN\_DIS* or the *LAN\_PCI\_DIS* in the "Software Defined Pins Control" word for the relevant port to 1.

The freed buffer space can be allocated to the active ports via the "Initialization Control 4" EEPROM word. Actual on-chip receive buffer allocated to the port can be read in the *IRPBS register*.

### 7.1.3.3 On-Chip Descriptor Buffers

The I350 contains a 16 descriptor cache for each receive queue used to reduce the latency of packet processing and to optimize the usage of PCIe bandwidth by fetching and writing back descriptors in bursts. The fetch and writeback algorithm are described in [Section 7.1.4.3](#) and [Section 7.1.4.4](#).

## 7.1.4 Receive Descriptors

### 7.1.4.1 Legacy Receive Descriptor Format

A receive descriptor is a data structure that contains the receive data buffer address and fields for hardware to store packet information. If *SRRCTL[n].DESCTYPE* = 000b, the I350 uses the legacy Receive descriptor as shown in [Table 7-4](#). The shaded areas indicate fields that are modified by hardware upon packet reception (so-called descriptor write-back).

**Note:** Legacy descriptors should not be used when advanced features such as Virtualization are activated.

**Table 7-4 Legacy Receive Descriptor (RDESC) Layout**

|   | 63                    | 48 47  | 40 39  | 32 31             | 16 15  | 0 |
|---|-----------------------|--------|--------|-------------------|--------|---|
| 0 | Buffer Address [63:0] |        |        |                   |        |   |
| 8 | VLAN Tag              | Errors | Status | Fragment Checksum | Length |   |

After receiving a packet for the I350, hardware stores the packet data into the indicated buffer and writes the length, packet checksum, status, errors, and status fields.

**Packet Buffer Address (64)** - Physical address of the packet buffer.

**Length Field (16)**

Length covers the data written to a receive buffer including CRC bytes (if any). Software must read multiple descriptors to determine the complete length for a packet that spans multiple receive buffers.

**Fragment Checksum (16)**

This field is used to provide the fragment checksum value. This field equals to the unadjusted 16-bit ones complement of the packet. Checksum calculation starts at the L4 layer (after the IP header) until the end of the packet excluding the CRC bytes. In order to use the fragment checksum assist to offload L4 checksum verification, software might need to back out some of the bytes in the packet. For more details see [Section 7.1.7.3](#)

**Status Field (8)**

Status information indicates whether the descriptor has been used and whether the referenced buffer is the last one for the packet. See [Table 7-5](#) for the layout of the *Status* field. Error status information is shown in [Figure 7-9](#).

**Table 7-5 Receive Status (RDESC.STATUS) Layout**

| 7   | 6    | 5    | 4     | 3  | 2   | 1   | 0  |
|-----|------|------|-------|----|-----|-----|----|
| PIF | IPCS | L4CS | UDPCS | VP | Rsv | EOP | DD |

- PIF (bit 7) - Passed imperfect filter only
- IPCS (bit 6) - IPv4 checksum calculated on packet
- L4CS (bit 5) - L4 (UDP or TCP) checksum calculated on packet
- UDPCS (bit 4) - UDP checksum or IP payload checksum calculated on packet.
- VP (bit 3) - Packet is 802.1q; indicates strip VLAN in 802.1q packet
- RSV (bit 2) - Reserved
- EOP (bit 1) - End of packet
- DD (bit 0) - Descriptor done

## EOP and DD

The following table lists the meaning of these bits:

**Table 7-6 Receive Status Bits**

| DD | EOP | Description                                                                                                                                                                                                                                                                   |
|----|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0b | 0b  | Software setting of the descriptor when it hands it off to the hardware.                                                                                                                                                                                                      |
| 0b | 1b  | Reserved (invalid option).                                                                                                                                                                                                                                                    |
| 1b | 0b  | A completion status indication for a non-last descriptor of a packet that spans across multiple descriptors. In a single packet case, DD indicates that the hardware is done with the descriptor and its buffers. Only the <i>Length</i> fields are valid on this descriptor. |
| 1b | 1b  | A completion status indication of the entire packet. Note that software Might take ownership of its descriptors. All fields in the descriptor are valid (reported by the hardware).                                                                                           |

## VP Field

The *VP* field indicates whether the incoming packet's type matches the VLAN Ethernet Type programmed in the *VET* Register. For example, if the packet is a VLAN (802.1q) type, it is set if the packet type matches *VET* and *CTRL.VME* is set (VLAN mode enabled). It also indicates that VLAN has been stripped from the 802.1q packet. For more details, see [Section 7.4](#).

## IPCS (IPv4 Checksum), L4CS (L4 Checksum), and UDPCS (UDP Checksum)

The meaning of these bits is shown in the table below:

**Table 7-7**      **IPCS, L4CS, and UDPCS**

| L4CS | UDPCS | IPCS    | Functionality                                                                                                                                                      |
|------|-------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0b   | 0b    | 0b      | Hardware does not provide checksum offload. Special case: Hardware does not provide UDP checksum offload for IPV4 packet with UDP checksum = 0b                    |
| 1b   | 0b    | 1b / 0b | Hardware provides IPv4 checksum offload if IPCS is active and TCP checksum is offload. A pass/fail indication is provided in the <i>Error</i> field – IPE and L4E. |
| 0b   | 1b    | 1b / 0b | Hardware provides IPv4 checksum offload if IPCS is active and UDP checksum is offload. A pass/fail indication is provided in the <i>Error</i> field – IPE and L4E. |

Refer to [Table 7-19](#) for a description of supported packet types for receive checksum offloading. Unsupported packet types do not have the *IPCS* or *L4CS* bits set. IPv6 packets do not have the *IPCS* bit set, but might have the *L4CS* bit set if the I350 recognized the TCP or UDP packet.

## PIF

Hardware supplies the *PIF* field to expedite software processing of packets. Software must examine any packet with *PIF* bit set to determine whether to accept the packet. If the *PIF* bit is clear, then the packet is known to be destined to this station, so software does not need to look at the packet contents. Multicast packets passing only the Multicast Vector (MTA) or unicast packets passing only the Unicast Hash Table (UTA) but not any of the MAC address exact filters (RAH, RAL) set the *PIF* bit. In addition, the following condition causes *PIF* to be cleared:

- The DA of the packet is a multicast address and promiscuous multicast is set (*RCTL.MPE* = 1b).
- The DA of the packet is a broadcast address and accept broadcast mode is set (*RCTL.BAM* = 1b)

A MAC control frame forwarded to the host (*RCTL.PMCF* = 0b) that does not match any of the exact filters, has the *PIF* bit set.

## Error Field (8)

Most error information appears only when the *store-bad-packet* bit (*RCTL.SBP*) is set and a bad packet is received. See [Table 7-8](#) for a definition of the possible errors and their bit positions.

**Table 7-8**      **RXE, IPE and L4E**

| 7   | 6   | 5   | 4        | 3 | 2 | 1 | 0 |
|-----|-----|-----|----------|---|---|---|---|
| RXE | IPE | L4E | Reserved |   |   |   |   |

- RXE (bit 7) - RX Data Error
- IPE (bit 6) - IPv4 Checksum Error
- L4E (bit 5) - TCP/UDP Checksum Error
- Reserved (bit 4:0)

## IPE/L4E

The IP and TCP/UDP checksum error bits from [Table 7-8](#) are valid only when the IPv4 or TCP/UDP checksum(s) is performed on the received packet as indicated via IPCS and L4CS. These, along with the other error bits, are valid only when the *EOP* and *DD* bits are set in the descriptor.

**Note:** Receive checksum errors have no effect on packet filtering.

If receive checksum offloading is disabled (*RXCSUM.IPOFLD* and *RXCSUM.TUOFLD*), the *IPE* and *L4E* bits are 0b.

## RXE

The RXE error bit is asserted in the following case:

1. CRC error is detected. CRC can be a result of reception of /V/ symbol on the TBI interface (see section 3.7.3.3.2) or assertion of RxERR on the MII/GMII interface or bad EOP or lose of sync during packet reception. Packets with a CRC error are posted to host memory only when *store-bad-packet* bit (*RCTL.SBP*) is set.

## VLAN Tag Field (16)

Hardware stores additional information in the receive descriptor for 802.1q packets. If the packet type is 802.1q (determined when a packet matches *VET* and *CTRL.VME* = 1b), then the *VLAN Tag* field records the VLAN information and the four-byte VLAN information is stripped from the packet data storage. Otherwise, the *VLAN Tag* field contains 0x0000. The rule for *VLAN tag* is to use network ordering (also called big endian). It appears in the following manner in the descriptor:

**Table 7-9 VLAN Tag Field Layout (for 802.1q Packet)**

|     |     |      |    |   |
|-----|-----|------|----|---|
| 15  | 13  | 12   | 11 | 0 |
| PRI | CFI | VLAN |    |   |

## 7.1.4.2 Advanced Receive Descriptors

### 7.1.4.2.1 Advanced Receive Descriptors (RDESC) - Read Format

[Table 7-10](#) shows the receive descriptor. This is the format that software writes to the descriptor queue and hardware reads from the descriptor queue in host memory. Hardware writes back the descriptor in a different format, shown in [Table 7-11](#).

**Table 7-10 RDESC Descriptor Read Format**

|   |                              |   |        |
|---|------------------------------|---|--------|
|   | 63                           | 1 | 0      |
| 0 | Packet Buffer Address [63:1] |   | A0/NSE |
| 8 | Header Buffer Address [63:1] |   | DD     |

**Packet Buffer Address (64)** - Physical address of the packet buffer. The lowest bit is either A0 (LSB of address) or NSE (No-Snoop Enable), depending on bit *RXCTL.RXdataWriteNSEn* of the relevant queue. See [Section 8.13.1](#).

**Header Buffer Address (64)** - Physical address of the header buffer. The lowest bit is DD.

**Note:** The I350 does not support null descriptors (a descriptor with a packet or header address that is always equal to zero).

When software sets the *NSE* bit in the receive descriptor, the I350 places the received packet associated with this descriptor in memory at the packet buffer address with *NSE* set in the PCIe attribute fields. *NSE* does not affect the data written to the header buffer address.

When a packet spans more than one descriptor, the header buffer address is not used for the second, third, etc. descriptors; only the packet buffer address is used in this case.

*NSE* is enabled for packet buffers that the software device driver knows have not been touched by the processor since the last time they were used, so the data cannot be in the processor cache and snoop is always a miss. Avoiding these snoop misses improves system performance. No-snoop is particularly useful when the DMA engine is moving the data from the packet buffer into application buffers, and the software device driver is using the information in the header buffer for its work with the packet.

**Note:** When No-Snoop Enable is used, relaxed ordering should also be enabled with *CTRL\_EXT.RO\_DIS*.

#### 7.1.4.2.2 Advanced Receive Descriptors (RDESC) - Writeback Format

When the I350 writes back the descriptors, it uses the descriptor format shown in [Table 7-11](#).

**Note:** *SRCTL[n].DESCTYPE* must be set to a value other than 000b for the I350 to write back the special descriptors.

**Table 7-11 RDESC Descriptor Write-Back Format**

|   | 63                                                        | 48 | 47      | 35 | 34 | 32 | 31             | 30           | 21 | 20             | 19              | 18  | 17          | 16 | 4        | 3 | 0 |
|---|-----------------------------------------------------------|----|---------|----|----|----|----------------|--------------|----|----------------|-----------------|-----|-------------|----|----------|---|---|
| 0 | RSS Hash Value/<br>{Fragment Checksum, IP identification} |    |         |    |    |    | SPH            | HDR_LEN[9:0] |    | HDR_LEN[11:10] |                 | RSV | Packet Type |    | RSS Type |   |   |
| 8 | VLAN Tag                                                  |    | PKT_LEN |    |    |    | Extended Error |              |    |                | Extended Status |     |             |    |          |   |   |

#### RSS Type (4)

**Table 7-12 RSS Type**

| Packet Type | Description                               |
|-------------|-------------------------------------------|
| 0x0         | No hash computation done for this packet. |
| 0x1         | HASH_TCP_IPV4                             |
| 0x2         | HASH_IPV4                                 |
| 0x3         | HASH_TCP_IPV6                             |
| 0x4         | HASH_IPV6_EX                              |
| 0x5         | HASH_IPV6                                 |
| 0x6         | HASH_TCP_IPV6_EX                          |
| 0x7         | HASH_UDP_IPV4                             |

**Table 7-12 RSS Type**

| Packet Type | Description      |
|-------------|------------------|
| 0x8         | HASH_UDP_IPV6    |
| 0x9         | HASH_UDP_IPV6_EX |
| 0xA:0xF     | Reserved         |

The I350 must identify the packet type and then choose the appropriate RSS hash function to be used on the packet. The RSS type reports the packet type that was used for the RSS hash function.

### Packet Type (13)

- VPKT (bit 12) - VLAN Packet indication

The 12 LSB bits of the packet type reports the packet type identified by the hardware as follows:

**Table 7-13 Packet Type LSB Bits (11:10)**

| Bit Index | Bit 11 = 0b                                                        | Bit 11 = 1b (L2 packet <sup>1</sup> )                                                                                                       |
|-----------|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 0         | IPv4 - Indicates IPv4 header present <sup>2</sup>                  | EtherType - ETQF register index that matches the packet. Special types might be defined for 1588, 802.1X, LLDP or any other requested type. |
| 1         | IPv4E - Indicates IPv4 Header includes IP options <sup>2</sup>     |                                                                                                                                             |
| 2         | IPv6 - Indicates IPv6 header present <sup>2 3 4</sup>              |                                                                                                                                             |
| 3         | IPv6E - Indicates IPv6 Header includes extensions <sup>2 3 4</sup> | Reserved                                                                                                                                    |
| 4         | TCP - Indicates TCP header present <sup>2 4 5</sup>                |                                                                                                                                             |
| 5         | UDP - Indicates UDP header present <sup>2 4 5</sup>                | Reserved                                                                                                                                    |
| 6         | SCTP - Indicates SCTP header present <sup>2 4 5</sup>              | Reserved                                                                                                                                    |
| 7         | NFS - Indicates NFS header present <sup>2 4 5</sup>                | Reserved                                                                                                                                    |
| 10:8      | Reserved                                                           | Reserved                                                                                                                                    |

- L2 packet (not L3 or L4 packet) with an EtherType that matches the *EType* field of one of the *ETQF[n]* registers that has the *ETQF[n].Filter enable* bit set to 1b.
- On unsupported tunneled frames only packet types of external IP header will be set if detected.
- When a packet is fragmented then the internal packet type bits on a supported tunneled packet (IPv6 tunneled in IPv4 only) won't be set.
- On supported tunneled frames (IPv6 tunneled in IPv4 only) then all the internal Packet types are set if detected (IPv6, IPv6E, TCP, UDP, SCTP and NFS)
- When a packet is fragmented the TCP, UDP, SCTP and NFS bits won't be set.

### RSV(5):

Reserved.

**HDR\_LEN (10)** - The length (bytes) of the header as parsed by the I350. In split mode when HBO (Header Buffer Overflow) is set in the Extended error field, the *HDR\_LEN* can be greater than zero though nothing is written to the header buffer. In header replication mode, the *HDR\_LEN* field does not reflect the size of the data actually stored in the header buffer because the I350 fills the buffer up to the size configured by *SRRCTL[n].BSIZEHEADER*, which might be larger than the header size reported here. This field is only valid in the first descriptor of a packet and should be ignored in all subsequent descriptors.

**Note:** When the packet is time stamped and the time stamp is placed at the beginning of the buffer the *RDESC.HDR\_LEN* field is updated with the additional time stamp bytes (16 bytes). For further information see [Section 7.1.6](#).

Packet types supported by the header split and header replication are listed in [Appendix B.1](#). Other packet types are posted sequentially in the host packet buffer. Each line in the following table has an enable bit in the *PSRTYPE* register. When one of the bits is set, the corresponding packet type is split. If the bit is not set, a packet matching the header layout is not split.

Header split and replication is described in [Section 7.1.5](#) while the packet types for this functionality are enabled by the *PSRTYPE[n]* registers ([Section 8.10.3](#)).

**Note:** The header of a fragmented IPv6 packet is defined before the fragmented extension header.

**SPH (1) - Split Header** - When set, indicates that the *HDR\_LEN* field reflects the length of the header found by hardware. If cleared, the *HDR\_LEN* field should be ignored. In the case where *SRRCTL[n].DESCTYPE* is set to *Header replication mode*, *SPH* bit is set but the *HDR\_LEN* field does not reflect the size of the data actually stored in the header buffer, because the I350 fills the buffer up to the size configured by *SRRCTL[n].BSIZEHEADER*.

### RSS Hash / {Fragment Checksum, IP identification} (32)

This field has multiplexed functionality according to the received packet type (reported on the *Packet Type* field in this descriptor) and device setting.

#### Fragment Checksum (16-Bit; 63:48)

The fragment checksum word contains the unadjusted one's complement checksum of the IP payload and is used to offload checksum verification for fragmented UDP packets as described in [Section 7.1.7.3](#). This field is mutually exclusive with the RSS hash. It is enabled when the *RXCSUM.PCSD* bit is cleared and the *RXCSUM.IPPCSE* bit is set.

#### IP identification (16-Bit; 47:32)

The IP identification word identifies the IP packet to whom this fragment belongs and is used to offload checksum verification for fragmented UDP packets as described in [Section 7.1.7.3](#). This field is mutually exclusive with the RSS hash. It is enabled when the *RXCSUM.PCSD* bit is cleared and the *RXCSUM.IPPCSE* bit is set.

#### RSS Hash Value (32)

The RSS hash value is required for RSS functionality as described in [Section 7.1.2.8](#). This bit is mutually exclusive with the fragment checksum. It is enabled when the *RXCSUM.PCSD* bit is set.

### Extended Status (20)

Status information indicates whether the descriptor has been used and whether the referenced buffer is the last one for the packet. [Table 7-14](#) lists the extended status word in the last descriptor of a packet (*EOP* is set). [Table 7-15](#) lists the extended status word in any descriptor but the last one of a packet (*EOP* is cleared).

**Table 7-14 Receive Status (RDESC.STATUS) Layout of the Last Descriptor**

| 19  | 18 | 17  | 16 | 15   | 14       | 13 | 12        | 11    | 10   |
|-----|----|-----|----|------|----------|----|-----------|-------|------|
| BMC | LB | Rsv | TS | TSIP | Reserved |    | Strip CRC | LLINT | UDPV |

**Table 7-14 Receive Status (RDESC.STATUS) Layout of the Last Descriptor**

|      |     |     |      |     |       |    |     |     |    |
|------|-----|-----|------|-----|-------|----|-----|-----|----|
| 19   | 18  | 17  | 16   | 15  | 14    | 13 | 12  | 11  | 10 |
| VEXT | Rsv | PIF | IPCS | L4I | UDPCS | VP | Rsv | EOP | DD |
| 9    | 8   | 7   | 6    | 5   | 4     | 3  | 2   | 1   | 0  |

**Table 7-15 Receive Status (RDESC.STATUS) Layout of Non-Last Descriptor**

|          |          |    |   |
|----------|----------|----|---|
| 19       | 2        | 1  | 0 |
| Reserved | EOP = 0b | DD |   |

BMC (19) - Packet received from BMC. The BMC bit is set to indicate the packet was sent by the local BMC. Bit is cleared if packet arrives from the network. For more details see [Section 10.4](#).

LB (18) - This bit provides a loopback status indication meaning that this packet is sent by a local virtual machine (VM to VM switch indication). For additional details see [Section 7.8.3](#).

TS (16) - Time Stamped Packet (Time Sync). The Time Stamp bit is set to indicate that the device recognized a Time Sync packet and time stamped it in the RXSTMPL/H time stamp registers (See [Section 7.9.3.2](#) and [Section 7.9.2.1](#)).

TSIP (15) - Timestamp in packet. The Timestamp In Packet bit is set to indicate that the received packet arrival time was captured by the hardware and the timestamp was placed in the receive buffer. For further details see [Section 7.1.6](#).

Reserved (2, 8, 14:13, 17) - Reserved at zero.

PIF (7), IPCS(6), UDPCS(4), VP(3), EOP (1), DD (0) - These bits are described in the legacy descriptor format in [Section 7.1.4](#).

L4I (5) - This bit indicates that an L4 integrity check was done on the packet, either TCP checksum, UDP checksum or SCTP CRC checksum. This bit is valid only for the last descriptor of the packet. An error in the integrity check is indicated by the L4E bit in the error field. The type of check done can be induced from the packet type bits 4, 5 and 6. If bit 4 is set, a TCP checksum was done. If bit 5 is set a UDP checksum was done, and if bit 6 is set, a SCTP CRC checksum was done.

VEXT (9) - First VLAN is found on a double VLAN packet. This bit is valid only when CTRL\_EXT.EXT\_VLAN is set. For more details see [Section 7.4.5](#).

UDPV (10) - This bit indicates that the incoming packet contains a valid (non-zero value) checksum field in an incoming first fragment UDP IPv4 packet. This means that the Fragment Checksum field in the receive descriptor contains the IP payload checksum as described in [Section 7.1.7.2](#). When this field is cleared in the first fragment that contains the UDP header, means that the packet does not contain a valid UDP checksum and the fragment checksum field in the Rx descriptor should be ignored. This field is always cleared in incoming fragments that do not contain the UDP header or in non fragmented packet.

LLINT (11) - This bit indicates that the packet caused an immediate interrupt via the low latency interrupt mechanism.

Strip CRC (12) - This bit indicates that Ethernet CRC has been stripped from incoming packet. Strip CRC operation is defined by the RCTL.SECRC bit for non virtualized mode and DVMOLR.STRCRC in virtualized mode.

**Note:** The non used field (RCTL.SECRC bit for virtualized mode and DVMOLR.STRCRC in non virtualized mode) should be cleared.

## Extended Error (12)

Table 7-16 and the text that follows describes the possible errors reported by hardware.

**Table 7-16 Receive Errors (RDESC.ERRORS) Layout**

| 11  | 10  | 9   | 8        | 7 | 6        | 4 | 3   | 2        | 0 |
|-----|-----|-----|----------|---|----------|---|-----|----------|---|
| RXE | IPE | L4E | Reserved |   | Reserved |   | HBO | Reserved |   |

#### RXE (bit 11)

RXE is described in the legacy descriptor format in [Section 7.1.4](#).

#### IPE (bit 10)

The IPE error indication is described in the legacy descriptor format in [Section 7.1.4](#).

#### L4E (bit 9)

L4 error indication - When set, indicates that hardware attempted to do an L4 integrity check as described in the *L4I* bit, but the check failed.

#### Reserved (bits 8:7)

#### Reserved (bits 6:4)

#### HBO (bit 3) - Header Buffer Overflow

**Note:** The *HBO* bit is relevant only if *SPH* is set.

1. In both header replication modes, *HBO* is set if the header size (as calculated by hardware) is bigger than the allocated buffer size (*SRRCTL.BSIZEHEADER*) but the replication still takes place up to the header buffer size. Hardware sets this bit in order to indicate to software that it needs to allocate bigger buffers for the headers.
2. In header split mode, when *SRRCTL[n] BSIZEHEADER* is smaller than *HDR\_LEN*, then *HBO* is set to 1b. In this case, the header is not split. Instead, the header resides within the host packet buffer. The *HDR\_LEN* field is still valid and equal to the calculated size of the header. However, the header is not copied into the header buffer.

**Note:** Most error information appears only when the *store-bad-packet* bit (*RCTL.SBP*) is set and a bad packet is received.

#### Reserved (bits 2:0) - Reserved

#### PKT\_LEN (16)

Number of bytes existing in the host packet buffer

The length covers the data written to a receive buffer including CRC bytes (if any). Software must read multiple descriptors to determine the complete length for packets that span multiple receive buffers. If *SRRCTL.DESC\_TYPE* = 4 (advanced descriptor header replication large packet only) and the total packet length is smaller than the size of the header buffer (no replication is done), this field continues to reflect the size of the packet, although no data is written to the packet buffer. Otherwise, if the buffer is not split because the header is bigger than the allocated header buffer, this field reflects the size of the data written to the first packet buffer (header and data).

**Note:** When the packet is time stamped and the time stamp is placed at the beginning of the buffer, the *RDESC.PKT\_LEN* field is updated with the additional time stamp bytes (16 bytes). For further information see [Section 7.1.6](#).

#### VLAN Tag (16)

These bits are described in the legacy descriptor format in [Section 7.1.4](#).

### 7.1.4.3 Receive Descriptor Fetching

The fetching algorithm attempts to make the best use of PCIe bandwidth by fetching a cache-line (or more) descriptor with each burst. The following paragraphs briefly describe the descriptor fetch algorithm and the software control provided.

When the `RXDCTL[n].ENABLE` bit is set and the on-chip descriptor cache is empty, a fetch happens as soon as any descriptors are made available (Host increments the `RDT[n]` tail pointer). When the on-chip buffer is nearly empty (defined by `RXDCTL.PTHRESH`), a prefetch is performed each time enough valid descriptors (defined by `RXDCTL.HTHRESH`) are available in host memory.

When the number of descriptors in host memory is greater than the available on-chip descriptor cache, the I350 might elect to perform a fetch that is not a multiple of cache-line size. Hardware performs this non-aligned fetch if doing so results in the next descriptor fetch being aligned on a cache-line boundary. This enables the descriptor fetch mechanism to be more efficient in the cases where it has fallen behind software.

All fetch decisions are based on the number of descriptors available and do not take into account any split of the transaction due to bus access limitations.

**Note:** The I350 NEVER fetches descriptors beyond the descriptor tail pointer.

### 7.1.4.4 Receive Descriptor Write-Back

Processors have cache-line sizes that are larger than the receive descriptor size (16 bytes). Consequently, writing back descriptor information for each received packet would cause expensive partial cache-line updates. A receive descriptor packing mechanism minimizes the occurrence of partial line write-backs.

To maximize memory efficiency, receive descriptors are packed together and written as a cache-line whenever possible. Descriptors write-backs accumulate and are opportunistically written out in cache line-oriented chunks, under the following scenarios:

- `RXDCTL[n].WTHRESH` descriptors have been used (the specified maximum threshold of unwritten used descriptors has been reached).
- The receive timer expires (`EITR`) - in this case all descriptors are flushed ignoring any cache-line boundaries.
- Explicit software flush (`RXDCTL.SWFLS`).
- Dynamic packets - if at least one of the descriptors that are waiting for write-back are classified as packets requiring immediate notification the entire queue is flushed out.

When the number of descriptors specified by `RXDCTL[n].WTHRESH` have been used, they are written back regardless of cache-line alignment. It is therefore recommended that `RXDCTL[n].WTHRESH` be a multiple of cache-line size. When the receive timer (`EITR`) expires, all used descriptors are forced to be written back prior to initiating the interrupt, for consistency. Software might explicitly flush accumulated descriptors by writing the `RXDCTL[n]` register with the `SWFLS` bit set.

When the I350 does a partial cache-line write-back, it attempts to recover to cache-line alignment on the next write-back.

For applications where the latency of received packets is more important than the bus efficiency and the CPU utilization, an *EITR* value of zero may be used. In this case, each receive descriptor will be written to the host immediately. If *RXDCTL[n].WTHRESH* equals zero, then each descriptor will be written back separately, otherwise, write back of descriptors may be coalesced if descriptor accumulates in the internal descriptor ring due to bandwidth constraints.

All write-back decisions are based on the number of descriptors available and do not take into account any split of the transaction due to bus access limitations.

### 7.1.4.5 Receive Descriptor Ring Structure

Figure 7-8 shows the structure of each of the 8 receive descriptor rings. Hardware maintains 8 circular queues of descriptors and writes back used descriptors just prior to advancing the head pointer(s). Head and tail pointers wrap back to base when size descriptors have been processed.

**Figure 7-8 Receive Descriptor Ring Structure**

Software inserts receive descriptors by advancing the tail pointer(s) to refer to the address of the entry just beyond the last valid descriptor. This is accomplished by writing the descriptor tail register(s) with the offset of the entry beyond the last valid descriptor. The hardware adjusts its internal tail pointer(s) accordingly. As packets arrive, they are stored in memory and the head pointer(s) is incremented by hardware. When the head pointer(s) is equal to the tail pointer(s), the queue(s) is empty. Hardware stops storing packets in system memory until software advances the tail pointer(s), making more receive buffers available.

The receive descriptor head and tail pointers reference to 16-byte blocks of memory. Shaded boxes in Figure 7-8 represent descriptors that have stored incoming packets but have not yet been recognized by software. Software can determine if a receive buffer is valid by reading the descriptors in memory. Any descriptor with a non-zero DD value has been processed by the hardware and is ready to be handled by the software.

**Note:** The head pointer points to the next descriptor that is written back. After the descriptor write-back operation completes, this pointer is incremented by the number of descriptors written back. Hardware owns all descriptors between [head... tail]. Any descriptor not in this range is owned by software.

The receive descriptor rings are described by the following registers:

- Receive Descriptor Base Address (*RDBA7* to *RDBA0*) register:  
This register indicates the start of the descriptor ring buffer. This 64-bit address is aligned on a 16-byte boundary and is stored in two consecutive 32-bit registers. Note that hardware ignores the lower 4 bits.
- Receive Descriptor Length (*RDLEN7* to *RDLEN0*) registers:  
This register determines the number of bytes allocated to the circular buffer. This value must be a multiple of 128 (the maximum cache-line size). Since each descriptor is 16 bytes in length, the total number of receive descriptors is always a multiple of eight.
- Receive Descriptor Head (*RDH7* to *RDH0*) registers:  
This register holds a value that is an offset from the base and indicates the in-progress descriptor. There can be up to 64 KB, 8 KB descriptors in the circular buffer. Hardware maintains a shadow copy that includes those descriptors completed but not yet stored in memory.
- Receive Descriptor Tail (*RDT7* to *RDT0*) registers:  
This register holds a value that is an offset from the base and identifies the location beyond the last descriptor hardware can process. This is the location where software writes the first new descriptor.

If software statically allocates buffers, uses legacy receive descriptors, and uses memory read to check for completed descriptors, it has to zero the status byte in the descriptor before bumping the tail pointer to make it ready for reuse by hardware. Zeroing the status byte is not a hardware requirement but is necessary for performing an in-memory scan.

All the registers controlling the descriptor rings behavior should be set before receive is enabled, apart from the tail registers that are used during the regular flow of data.

#### 7.1.4.5.1 Low Receive Descriptors Threshold

As described above, the size of the receive queues is measured by the number of receive descriptors. During run time the software processes completed descriptors and then increments the Receive Descriptor Tail registers (*RDT*). At the same time, the hardware may post new packets received from the LAN that increments the Receive Descriptor Head registers (*RDH*) for each used descriptor.

The number of usable (free) descriptors for the hardware is the distance between Tail and Head registers. When the Tail reaches the Head, there are no free descriptors and further packets may be either dropped or block the receive FIFO. In order to avoid this behavior, the I350 may generate a low latency interrupt (associated with the relevant receive queue) once the amount of free descriptors is less or equal than the threshold. The threshold is defined in 16 descriptors granularity per queue in the *SRRCTL[n].RDMTS* field.

## 7.1.5 Header Splitting and Replication

### 7.1.5.1 Purpose

This feature consists of splitting or replicating packet's header to a different memory space. This helps the host to fetch headers only for processing: headers are replicated through a regular snoop transaction in order to be processed by the host CPU. It is recommended to perform this transaction with the DCA feature enabled (see [Section 8.13](#)) or in conjunction with a software-prefetch.

The packet (header and payload) is stored in memory through a (optionally) non-snoop transaction. Later, a data movement engine transaction moves the payload from the software device driver buffer to application memory or it is moved using a normal memory copy operation.

The I350 supports header splitting in several modes:

- Legacy mode: legacy descriptors are used; headers and payloads are not split.
- Advanced mode, no split: advanced descriptors are in use; header and payload are not split.
- Advanced mode, split: advanced descriptors are in use; header and payload are split to different buffers. If the packet cannot be split, only the packet buffer is used.
- Advanced mode, replication: advanced descriptors are in use; header is replicated in a separate buffer and also in a payload buffer.
- Advanced mode, replication, conditioned by packet size: advanced descriptors are in use; replication is performed only if the packet is larger than the header buffer size.

### 7.1.5.2 Description

In [Figure 7-9](#) and [Figure 7-10](#), the header splitting and header replication modes are shown.

**Figure 7-9 Header Splitting**

**Figure 7-10 Header Replication**

The physical address of each buffer is written in the *Buffer Addresses* fields. The sizes of these buffers are statically defined by *BSIZEPACKET* and *BSIZEHEADER* fields in the *SRRCTL[n]* registers.

The packet buffer address includes the address of the buffer assigned to the replicated packet, including header and data payload portions of the received packet. In the case of a split header, only the payload is included.

The header buffer address includes the address of the buffer that contains the header information. The receive DMA module stores the header portion of the received packets into this buffer.

The I350 uses the packet replication or splitting feature when the *SRRCTL[n].DESCTYPE* is larger than one. The software device driver must also program the buffer sizes in the *SRRCTL[n]* registers.

When header split is selected, the packet is split only on selected types of packets. A bit exists for each option in *PSRTYPE[n]* registers so several options can be used in conjunction with them. If one or more bits are set, the splitting is performed for the corresponding packet type. See [Appendix B.1](#) for details on the possible headers type supported).

The following table lists the behavior of the I350 in the different modes.

**Table 7-17 I350 Split/Replicated Header Behavior**

| DESCTYPE | Condition                      | SPH | HBO | PKT_LEN                                               | HDR_LEN                  | Header and Payload DMA                            |
|----------|--------------------------------|-----|-----|-------------------------------------------------------|--------------------------|---------------------------------------------------|
| Split    | 1. Header can't be decoded     | 0b  | 0b  | Min(Packet length, <i>BSIZEPACKET</i> )               | N/A                      | Header + Payload ⇒ Packet buffer                  |
|          | 2. Header ≤ <i>BSIZEHEADER</i> | 1b  | 0b  | Min(Payload length, <i>BSIZEPACKET</i> ) <sup>1</sup> | Header size              | Header ⇒ Header buffer<br>Payload ⇒ Packet buffer |
|          | 3. Header > <i>BSIZEHEADER</i> | 1b  | 1b  | Min(Packet length, <i>BSIZEPACKET</i> )               | Header size <sup>2</sup> | Header + Payload ⇒ Packet buffer                  |

**Table 7-17 I350 Split/Replicated Header Behavior**

| DESCTYPE                    | Condition                      | SPH             | HBO                | PKT_LEN                         | HDR_LEN     | Header and Payload DMA                                                                            |
|-----------------------------|--------------------------------|-----------------|--------------------|---------------------------------|-------------|---------------------------------------------------------------------------------------------------|
| Replicate                   | 1. Header can't be decoded     | 0b <sup>3</sup> | 0b                 | Min(Packet length, BSIZEPACKET) | N/A         | (Header + Payload) (partial <sup>5</sup> )<br>⇒ Header buffer<br>Header + Payload ⇒ Packet buffer |
|                             | 2. Packet length ≤ BSIZEHEADER | 1b <sup>3</sup> | 0b                 | Min(Packet length, BSIZEPACKET) | Header size | Header + Payload ⇒ Header buffer<br>Header + Payload ⇒ Packet buffer                              |
|                             | 3. Packet length > BSIZEHEADER | 1b <sup>3</sup> | 0b/1b <sup>4</sup> | Min(Packet length, BSIZEPACKET) | Header size | Header + Payload (partial <sup>5</sup> ) ⇒ Header buffer<br>Header + Payload ⇒ Packet buffer      |
| Replicate Large Packet only | 1. Header can't be decoded     | 0b <sup>3</sup> | 0b                 | Min(Packet length, BSIZEPACKET) | N/A         | (Header + Payload) (partial <sup>5</sup> )<br>⇒ Header buffer<br>Header + Payload ⇒ Packet buffer |
|                             | 2. Packet length ≤ BSIZEHEADER | 1b <sup>3</sup> | 0b                 | Packet length                   | Header size | Header + Payload ⇒ Header buffer                                                                  |
|                             | 2. Packet length > BSIZEHEADER | 1b <sup>3</sup> | 0b/1b <sup>5</sup> | Min(Packet length, BSIZEPACKET) | Header size | (Header + Payload) (partial <sup>5</sup> )<br>⇒ Header buffer<br>Header + Payload ⇒ Packet buffer |

1. In a header only packet (such as TCP ACK packet), the PKT\_LEN is zero.
2. The HDR\_LEN doesn't reflect the actual data size stored in the Header buffer. It reflects the header size determined by the parser. When timestamp in packet is enabled header size reflects the additional 16 bytes of the timestamp.
3. In replicate mode if SPH = 0b due to no match to any of the headers selected in the PSRTYPE[n] register, then the header size is not relevant. In any case, even if SPH = 1b due to match to one of the headers selected in the PSRTYPE[n] register, the HDR\_LEN doesn't reflect the actual data size stored in the header buffer.
4. HBO is 1b if the header size is bigger than BSIZEHEADER and zero otherwise.
5. Partial means up to BSIZEHEADER

#### Software Notes:

- If SRRCTL[n].NSE is set, all buffers' addresses in a packet descriptor must be word aligned.
- Packet header can't span across buffers, therefore, the size of the header buffer must be larger than any expected header size. Otherwise, only the part of the header fitting the header buffer is replicated. In the case of header split mode (SRRCTL[n].DESCTYPE = 010b), a packet with a header larger than the header buffer is not split.
- [Section B.1](#) describes the details of the split/replicate conditions for different types of headers according to the settings of the PSRTYPE register values.

## 7.1.6 Receive Packet Timestamp in Buffer

The I350 supports adding an optional tailored header before the MAC header of the packet in the receive buffer. The 64 MSB bits of the 128 bit tailored header include a timestamp composed of the packet reception time measured in the SYSTIML (Low DW) and SYSTIMH (High DW) registers (See [Section 7.9.3.1](#) for further information on SYSTIML/H operation). The 64 LSB bits of the tailored header are reserved.

The timestamp information is placed in Networking order (Big Endian) format as depicted in [Table 7-18](#).

**Table 7-18 Timestamp Layout in Buffer**

| 0              | 3 | 4              | 7 | 8       | 11 | 12      | 15 | 16...           |
|----------------|---|----------------|---|---------|----|---------|----|-----------------|
| Reserved (0x0) |   | Reserved (0x0) |   | SYSTIMH |    | SYSTIML |    | Received Packet |

When the *TSAUXC.Disable systime* bit is cleared and the *SRRCTL[n].Timestamp* bit is set to 1, packets received to the queue will be time stamped if they meet one of the following conditions:

- Meet the criteria defined in the *TSYNCRXCTL.Type* field (See [Section 8.16.1](#) and [Section 8.16.26](#)).
- Match the value defined in one of the *ETQF* registers with the *1588 time stamp* bit set (See [Section 7.1.2.4](#)) if *TSYNCRXCTL.Type* field defines time stamping of L2 packets.
- Match a 2-tuple filter with the *TTQF.1588 time stamp* set (See [Section 7.1.2.5](#)) if *TSYNCRXCTL.Type* field defines time stamping of L4 packets.

When detecting a receive packet that should be time stamped, the I350 will:

- Place a 64 bit timestamp, indicating the time a packet was received by the MAC, at the beginning of the receive buffer before the received packet.
- Set the *TSIP* bit in the *RDESC.STATUS* field of the last receive descriptor.
- Update the *RDESC.Packet Type* field in the last receive descriptor. Value in this field enables identifying that this is a PTP (Precision Time Protocol) packet (this indication is only relevant for L2 packets).
- Update the *RDESC.HDR\_LEN* and *RDESC.PKT\_LEN* values to include size of timestamp.

Software driver should take into account the additional size of the timestamp when preparing the receive descriptors for the relevant queue.

## 7.1.7 Receive Packet Checksum and SCTP CRC Off Loading

The I350 supports the off loading of four receive checksum calculations: packet checksum, fragment payload checksum, the IPv4 header checksum, and the TCP/UDP checksum. In addition, SCTP CRC32 calculation is supported as described in [Section 7.1.7.4](#)

The packet checksum and the fragment payload checksum shares the same location as the RSS field and is reported in the receive descriptor when the *RXCSUM.PCSD* bit is cleared. If the *RXCSUM.IPPCSE* is set, the Packet checksum is aimed to accelerate checksum calculation of fragmented UDP packets. Please refer to [Section 7.1.7.3](#) for a detailed explanation. If *RXCSUM.IPPCSE* is cleared (the default value), the checksum calculation that is reported in the Rx Packet checksum field is the unadjusted 16-bit one's complement of the packet as described in [Section 7.1.7.2](#)

For supported packet/frame types, the entire checksum calculation can be off loaded to the I350. If *RXCSUM.IPOFLD* is set to 1b, the I350 calculates the IPv4 checksum and indicates a pass/fail indication to software via the IPv4 Checksum Error bit (*RDESC.IPE*) in the *Error* field of the receive descriptor. Similarly, if *RXCSUM.TUOFLD* is set to 1b, the I350 calculates the TCP or UDP checksum and indicates a pass/fail condition to software via the TCP/UDP Checksum Error bit (*RDESC.L4E*). These error bits are valid when the respective status bits indicate the checksum was calculated for the packet (*RDESC.IPCS* and *RDESC.L4CS*, respectively).

If neither *RXCSUM.IPOFLD* nor *RXCSUM.TUOFLD* are set, the *Checksum Error* bits (*IPE* and *L4E*) are 0b for all packets.

Supported frame types:

- Ethernet II
- Ethernet SNAP

**Table 7-19 Supported Receive Checksum Capabilities**

| Packet Type                                                                                                                                                                                                                                                                                                                  | Hardware IP Checksum Calculation                                     | Hardware TCP/UDP Checksum Calculation | Hardware SCTP CRC calculation |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|---------------------------------------|-------------------------------|
| IPv4 packets.                                                                                                                                                                                                                                                                                                                | Yes                                                                  | Yes                                   | Yes                           |
| IPv6 packets.                                                                                                                                                                                                                                                                                                                | No (n/a)                                                             | Yes                                   | Yes                           |

| IPv6 tunnels: <ul style="list-style-type: none"> <li>IPv4 packet in an IPv6 tunnel.</li> <li>IPv6 packet in an IPv6 tunnel.</li> </ul>                                                                                                                                                                                       | No<br>No                                                             | No<br>No                              | No<br>No                      |
| Packet is an IPv4 fragment.                                                                                                                                                                                                                                                                                                  | Yes                                                                  | No <sup>2</sup>                       | No                            |
| Packet is greater than 1518, 1522 or 1526 bytes (LPE=1b) <sup>3</sup> .                                                                                                                                                                                                                                                      | Yes                                                                  | Yes                                   | Yes                           |
| Packet has 802.3ac tag.                                                                                                                                                                                                                                                                                                      | Yes                                                                  | Yes                                   | Yes                           |
| IPv4 packet has IP options (IP header is longer than 20 bytes).                                                                                                                                                                                                                                                              | Yes                                                                  | Yes                                   | Yes                           |
| Packet has TCP or UDP options.                                                                                                                                                                                                                                                                                               | Yes                                                                  | Yes                                   | Yes                           |
| IP header's protocol field contains a protocol number other than TCP or UDP or SCTP.                                                                                                                                                                                                                                         | Yes                                                                  | No                                    | No                            |

1. The IPv6 header portion can include supported extension headers as described in the "IPv6 packet with next header options" row.
2. UDP checksum of first fragment is supported.
3. Depends on number of VLAN tags.

### 7.1.7.1 Filters Details

The previous table lists general details about what packets are processed. In more detail, the packets are passed through a series of filters to determine if a receive checksum is calculated:

#### 7.1.7.1.1 MAC Address Filter

This filter checks the MAC destination address to be sure it is valid (such as IA match, broadcast, multicast, etc.). The receive configuration settings determine which MAC addresses are accepted. See the various receive control configuration registers such as *RCTL* (*RCTL.UPE*, *RCTL.MPE*, *RCTL.BAM*), *MTA*, *RAL*, and *RAH*.

#### 7.1.7.1.2 SNAP/VLAN Filter

This filter checks the next headers looking for an IP header. It is capable of decoding Ethernet II, Ethernet SNAP, and IEEE 802.3ac headers. It skips past any of these intermediate headers and looks for the IP header. The receive configuration settings determine which next headers are accepted. See the various receive control configuration registers such as *RCTL* (*RCTL.VFE*), *VET*, and *VFTA*.

### 7.1.7.1.3 IPv4 Filter

This filter checks for valid IPv4 headers. The version field is checked for a correct value (4).

IPv4 headers are accepted if they are any size greater than or equal to five (Dwords). If the IPv4 header is properly decoded, the IP checksum is checked for validity. The *RXCSUM.IPOFLD* bit must be set for this filter to pass.

### 7.1.7.1.4 IPv6 Filter

This filter checks for valid IPv6 headers, which are a fixed size and have no checksum. The IPv6 extension headers accepted are: hop-by-hop, destination options, and routing. The maximum size next header accepted is 16 Dwords (64 bytes).

### 7.1.7.1.5 IPv6 Extension Headers

IPv4 and TCP provide header lengths, which enable hardware to easily navigate through these headers on packet reception for calculating checksum and CRCs, etc. For receiving IPv6 packets; however, there is no IP header length to help hardware find the packet's ULP (such as TCP or UDP) header. One or more IPv6 extension headers might exist in a packet between the basic IPv6 header and the ULP header. The hardware must skip over these extension headers to calculate the TCP or UDP checksum for received packets.

The IPv6 header length without extensions is 40 bytes. The IPv6 field *Next Header Type* indicates what type of header follows the IPv6 header at offset 40. It might be an upper layer protocol header such as TCP or UDP (*Next Header Type* of 6 or 17, respectively), or it might indicate that an extension header follows. The final extension header indicates with its *Next Header Type* field the type of ULP header for the packet.

IPv6 extension headers have a specified order. However, destinations must be able to process these headers in any order. Also, IPv6 (or IPv4) might be tunneled using IPv6, and thus another IPv6 (or IPv4) header and potentially its extension headers might be found after the extension headers.

The IPv4 *Next Header Type* is at byte offset nine. In IPv6, the first *Next Header Type* is at byte offset six.

All IPv6 extension headers have the *Next Header Type* in their first eight bits. Most have the length in the second eight bits (Offset Byte[1]) as shown:

**Table 7-20 Typical IPv6 Extended Header Format (Traditional Representation)**

| <div>01234567</div> |  |  |  |  |  |  |  | <div>89012345</div> |  |  |  |  |  |  |  | <div>6789012345678901</div> |  |  |  |  |  |  |  |
|---------------------|--|--|--|--|--|--|--|---------------------|--|--|--|--|--|--|--|-----------------------------|--|--|--|--|--|--|--|
| Next Header Type    |  |  |  |  |  |  |  | Length              |  |  |  |  |  |  |  |                             |  |  |  |  |  |  |  |
|                     |  |  |  |  |  |  |  |                     |  |  |  |  |  |  |  |                             |  |  |  |  |  |  |  |

The following table lists the encoding of the *Next Header Type* field and information on determining each header type's length. The IPv6 extension headers are not otherwise processed by the I350 so their details are not covered here.

**Table 7-21 Header Type Encoding and Lengths**

| Header                         | Next Header Type | Header Length<br>(Units are Bytes Unless Otherwise Specified) |
|--------------------------------|------------------|---------------------------------------------------------------|
| IPv6                           | 6                | Always 40 bytes                                               |
| IPv4                           | 4                | Offset Bits[7:4]<br>Unit = 4 bytes                            |
| TCP                            | 6                | Offset Byte[12].Bits[7:4]<br>Unit = 4 bytes                   |
| UDP                            | 17               | Always 8 bytes                                                |
| Hop by Hop Options             | 0 (Note 1)       | 8+Offset Byte[1]                                              |
| Destination Options            | 60               | 8+Offset Byte[1]                                              |
| Routing                        | 43               | 8+Offset Byte[1]                                              |
| Fragment                       | 44               | Always 8 bytes                                                |
| Authentication                 | 51               | 8+4*(Offset Byte[1])                                          |
| Encapsulating Security Payload | 50               | Note 3                                                        |
| No Next Header                 | 59               | Note 2                                                        |

**Notes:**

1. Hop-by-hop options header is only found in the first *Next Header Type* of an IPv6 header.
2. When a *No Next Header* type is encountered, the rest of the packet should not be processed.
3. Encapsulated security payload - the I350 cannot offload packets with this header type.

Note that the I350 hardware acceleration does not support all IPv6 extension header types (refer to [Table 7-19](#)).

### 7.1.7.1.6 UDP/TCP Filter

This filter checks for a valid UDP or TCP header. The prototype next header values are 0x11 and 0x06, respectively. The *RXCSUM.TUOFLD* bit must be set for this filter to pass.

### 7.1.7.2 Packet Checksum

This feature allows raw checksum of part of the packet, independent of the protocol identified. This feature can not be used together with the receive UDP fragment checksum described in the next section.

The packet checksum is the 16-bit one's complement of the received packet, starting from the byte indicated by *RXCSUM.PCSS* (zero corresponds to the first byte of the packet).

For packets with a VLAN header, the packet checksum includes the header if VLAN striping is not enabled by the *CTRL.VME*. If a VLAN header strip is enabled using *CTRL.VME*, the packet checksum and the starting offset of the packet checksum exclude the VLAN header due to masking of VLAN header.

For example, for an Ethernet II frame encapsulated as an 802.3ac VLAN packet and *CTRL.VME* is set and with *RXCSUM.PCSS* set to 14, the packet checksum would include the entire encapsulated frame, excluding the 14-byte Ethernet header (DA, SA, type/length) and the 4-byte q-tag.

**Note:** If VLAN strip is enabled via the per queue *DVMOLR.STRVLAN* field, the packet checksum includes the VLAN header.

The packet checksum does not include the Ethernet CRC if the *RCTL.SECRC* bit is set.

Software must make the required offsetting computation (to remove the bytes that should not have been included and to include the pseudo-header) prior to comparing the packet checksum against the TCP checksum stored in the packet.

**Note:** The *RXCSUM.PCSS* value should point to a field that is before or equal to the IP header start. Otherwise the IP header checksum or TCP/UDP checksum is not calculated correctly.

### 7.1.7.3 Receive UDP Fragmentation Checksum

The I350 might provide receive fragmented UDP checksum offload. The I350 should be configured in the following manner to enable this mode:

The *RXCSUM.PCSD* bit should be cleared. The *Fragment Checksum* and *IP Identification* fields are mutually exclusive with the RSS hash. When the *RXCSUM.PCSD* bit is cleared, *Fragment Checksum* and *IP Identification* are active instead of RSS hash.

The *RXCSUM.IPPCSE* bit should be set. This field enables the IP payload checksum enable that is designed for the fragmented UDP checksum.

The *RXCSUM.PCSS* field must be zero. The packet checksum start should be zero to enable auto-start of the checksum calculation. The following table lists the exact description of the checksum calculation.

The following table also lists the outcome descriptor fields for the following incoming packets types:

**Table 7-22 Descriptor Fields**

| Incoming Packet Type                     | Fragment Checksum (if <i>RXCSUM.PCSD</i> is cleared)        | UDPV                                             | UDPCS / L4CS / L4I           |
|------------------------------------------|-------------------------------------------------------------|--------------------------------------------------|------------------------------|
| Non IP Packet                            | Packet checksum                                             | 0b                                               | 0b / 0b / 0b                 |
| IPv6 Packet                              | Packet checksum                                             | 0b                                               | Depends on transport header. |
| Non fragmented IPv4 packet               | Packet checksum                                             | 0b                                               | Depends on transport header. |
| Fragmented IPv4, when not first fragment | The unadjusted one's complement checksum of the IP payload. | 0b                                               | 1b / 0b / 0b                 |
| Fragmented IPv4, for the first fragment  | Same as above                                               | 1 if the UDP header checksum is valid (not zero) | 1b / 0b / 0b                 |

**Note:** When the software device driver computes the 16-bit ones complement, the sum on the incoming packets of the UDP fragments, it should expect a value of 0xFFFF. Refer to [Section 7.1.7](#) for supported packet formats.

### 7.1.7.4 SCTP Offload

If a receive packet is identified as SCTP, the I350 checks the CRC32 checksum of this packet if the *RXCSUM.CRCOFL* bit is set to 1b and identifies this packet as SCTP. Software is notified on the execution of the CRC check via the *L4I* bit in the *Extended Status* field of the Rx descriptor and is notified on detection of a CRC error via the *L4E* bit in the *Extended Error* field of the Rx descriptor. The detection of a SCTP packet is indicated via the *SCTP* bit in the *packet Type* field of the Rx descriptor. The following SCTP packet format is expected to enable support of the SCTP CRC check:

**Table 7-23 SCTP Header**

|                     |  |  |  |  |  |  |  |                      |  |  |  |  |  |  |  |                      |  |  |  |  |  |  |  |                      |  |  |  |  |  |  |  |

## 7.2 Transmit Functionality

### 7.2.1 Packet Transmission

Output packets to be transmitted are created using pointer-length pairs constituting a descriptor chain (descriptor based transmission). Software forms transmit packets by assembling the list of pointer-length pairs, storing this information in one of the transmit descriptor rings, and then updating the adequate on-chip transmit tail pointer. The transmit descriptors and buffers are stored in host memory. Hardware typically transmits the packet only after it has completely fetched all the packet data from host memory and stored it into the on-chip transmit FIFO (store and forward architecture). This permits TCP or UDP checksum computation and avoids problems with PCIe under-runs. Another transmit feature of the I350 is TCP/UDP segmentation. The hardware has the capability to perform packet segmentation on large data buffers offloaded from the Network Stack. This feature is discussed in detail in [Section 7.2.4](#).

In addition, the I350 supports SCTP offloading for transmit requests. See section [Section 7.2.5.3](#) for details about SCTP.

[Table 1-10](#) provides a high level description of all data/control transformation steps needed for sending Ethernet packets to the line.

#### 7.2.1.1 Transmit Data Storage

Data is stored in buffers pointed to by the descriptors. The data can be aligned to arbitrary byte boundary with the maximum size per descriptor limited only to the maximum allowed packet size (9728 bytes). A packet typically consists of two (or more) buffers, one (or more) for the header and one for the actual data. Each buffer is referenced by a different descriptor. Some software implementations may copy the header(s) and packet data into one buffer and use only one descriptor per transmitted packet.

#### 7.2.1.2 On-Chip Transmit Buffers

The I350 allocates by default a 20KB on-chip packet buffer per port. The buffers are used to store packets until they are transmitted on the line. The I350 utilizes a common memory structure for the on-chip transmit buffers allocated to the various ports. If a port is disabled, so that it can't be accessed by host and management, the freed buffer space can be allocated to the active ports via the "Initialization Control 4" EEPROM word. A port can be disabled by either:

1. Pin assertion (LAN0\_DIS\_N, LAN1\_DIS\_N, LAN2\_DIS\_N, LAN3\_DIS\_N for port 0 to 3 respectively) and setting the EEPROM bit *PHY\_in\_LAN\_disable* in the “Software Defined Pins Control” word to 1 for the relevant port.
2. Setting EEPROM bit *LAN\_DIS* in the “Software Defined Pins Control” word for the relevant port to 1.

Actual on-chip transmit buffer allocated to the port can be read in the *ITPBS* register.

### 7.2.1.3 On-Chip Descriptor Buffers

The I350 contains a 24 descriptor cache for each transmit queue used to reduce the latency of packet processing and to optimize the usage of the PCIe bandwidth by fetching and writing back descriptors in bursts. The fetch and writeback algorithm are described in [Section 7.2.2.5](#) and [Section 7.2.2.6](#).

### 7.2.1.4 Transmit Contexts

The I350 provides hardware checksum offload and TCP/UDP segmentation facilities. These features enable TCP and UDP packet types to be handled more efficiently by performing additional work in hardware, thus reducing the software overhead associated with preparing these packets for transmission. Part of the parameters used by these features is handled through context descriptors.

A context descriptor refers to a set of device registers loaded or accessed as a group to provide a particular function. The I350 supports 2x8 context descriptor sets (two per queue) per port on-chip. The transmit queues can contain transmit data descriptors (similar to the receive queue) as well as transmit context descriptors.

The contexts are queue specific and one context cannot be reused from one queue to another. This differs from the method used in previous devices that supported a pool of contexts to be shared between queues.

A transmit context descriptor differs from a data descriptor as it does not point to packet data. Instead, this descriptor provides the ability to write to the on-chip context register sets that support the transmit checksum offloading and the segmentation features of the I350.

The I350 supports one type of transmit context. This on-chip context is written with a transmit context descriptor DTYP=2 and is always used as context for transmit data descriptor DTYP=3.

The *IDX* field contains an index to one of the two queue contexts. Software must track what context is stored in each *IDX* location.

Each advanced data descriptor that uses any of the advanced offloading features must refer to a context.

Contexts can be initialized with a transmit context descriptor and then used for a series of related transmit data descriptors. The context, for example, defines the checksum and offload capabilities for a given type of TCP/IP flow. All packets of this type can be sent using this context.

Software is responsible for ensuring that a context is only overwritten when it is no longer needed. Hardware does not include any logic to manage the on-chip contexts; it is completely up to software to populate and then use the on-chip context table.

**Note:** Software should not queue more than 2 context descriptors in sequence without an intervening data descriptor, to achieve adequate performance.

Each context defines information about the packet sent including the total size of the MAC header (*TDESC.MACLEN*), the maximum amount of payload data that should be included in each packet (*TDESC.MSS*), UDP or TCP header length (*TDESC.L4LEN*), IP header length (*TDESC.IPLEN*), and information about what type of protocol (TCP, IP, etc.) is used. Other than TCP, IP (*TDESC.TUCMD*), most information is specific to the segmentation capability.

Because there are dedicated on-chip resources for contexts, they remain constant until they are modified by another context descriptor. This means that a context can be used for multiple packets (or multiple segmentation blocks) unless a new context is loaded prior to each new packet. Depending on the environment, it might be unnecessary to load a new context for each packet. For example, if most traffic generated from a given node is standard TCP frames, this context could be setup once and used for many frames. Only when some other frame type is required would a new context need to be loaded by software. This new context could use a different index or the same index.

This same logic can also be applied to the TCP/UDP segmentation scenario, though the environment is a more restrictive one. In this scenario, the host is commonly asked to send messages of the same type, TCP/IP for instance, and these messages also have the same Maximum Segment Size (MSS). In this instance, the same context could be used for multiple TCP messages that require hardware segmentation.

## 7.2.2 Transmit Descriptors

The I350 supports legacy descriptors and I350 advanced descriptors.

Legacy descriptors are intended to support legacy drivers to enable fast platform power up and to facilitate debug.

**Note:** These descriptors should not be used when advanced features such as virtualization are used. If legacy descriptors are used when virtualization is enabled such as when *TXSWC.Loopback* enable or *STATUS.VFE* or one of the *TXSWC.MACAS* bits or one of the *TXSWC.VLANAS* bits are set, the packets are ignored and not sent.

The Legacy descriptors are recognized as such based on the *DEXT* bit as discussed later in this section.

In addition, the I350 supports two types of advanced transmit descriptors:

1. Advanced Transmit Context Descriptor, *DTYP* = 0010b.
2. Advanced Transmit Data Descriptor, *DTYP* = 0011b.

**Note:** *DTYP* values 0000b and 0001b are reserved.

The transmit data descriptor (both legacy and advanced) points to a block of packet data to be transmitted. The advanced transmit context descriptor does not point to packet data. It contains control/context information that is loaded into on-chip registers that affect the processing of packets for transmission. The following sections describe the descriptor formats.

### 7.2.2.1 Legacy Transmit Descriptor Format

Legacy descriptors are identified by having bit 29 of the descriptor (*TDESC.DEXT*) set to 0b. In this case, the descriptor format is defined as shown in [Table 7-24](#). Note that the address and length must be supplied by software. Also note that bits in the command byte are optional, as are the CSO, and CSS fields.

**Table 7-24 Transmit Descriptor (TDESC) Fetch Layout - Legacy Mode**

|   | 63                    | 48 | 47  | 40 | 39       | 36 | 35  | 32 | 31  | 24 | 23  | 16 | 15     | 0 |
|---|-----------------------|----|-----|----|----------|----|-----|----|-----|----|-----|----|--------|---|
| 0 | Buffer Address [63:0] |    |     |    |          |    |     |    |     |    |     |    |        |   |
| 8 | VLAN                  |    | CSS |    | Reserved |    | STA |    | CMD |    | CSO |    | Length |   |

**Table 7-25 Transmit Descriptor (TDESC) Write-Back Layout - Legacy Mode**

|   | 63       | 48 | 47  | 40 | 39       | 36 | 35  | 32 | 31       | 24 | 23  | 16 | 15     | 0 |
|---|----------|----|-----|----|----------|----|-----|----|----------|----|-----|----|--------|---|
| 0 | Reserved |    |     |    |          |    |     |    | Reserved |    |     |    |        |   |
| 8 | VLAN     |    | CSS |    | Reserved |    | STA |    | CMD      |    | CSO |    | Length |   |

**Note:** For frames that span multiple descriptors, the *VLAN*, *CSS*, *CSO*, *CMD.VLE*, *CMD.IC*, and *CMD.IFCS* are valid only in the first descriptors and are ignored in the subsequent ones.

#### 7.2.2.1.1 Buffer Address (64)

Physical address of a data buffer in host memory that contains a portion of a transmit packet.

#### 7.2.2.1.2 Length

Length (*TDESC.LENGTH*) specifies the length in bytes to be fetched from the buffer address provided.

The maximum length associated with any single legacy descriptor is 9728 bytes.

Descriptor length(s) might be limited by the size of the transmit FIFO. All buffers comprising a single packet must be able to be stored simultaneously in the transmit FIFO. For any individual packet, the sum of the individual descriptors' lengths must be below 9728 bytes.

**Note:** The maximum allowable packet size for transmits can change, based on the value written to the *DMA TX Max Allowable packet size (DTXMXPkTSZ)* register.

Descriptors with zero length (null descriptors) transfer no data. Null descriptors can only appear between packets and must have their *EOP* bits set.

If the *TCTL.PSP* bit is set, the total length of the packet transmitted, not including FCS should be at least 17 bytes. If bit is cleared the total length of the packet transmitted, not including FCS should be at least 60 bytes.

#### 7.2.2.1.3 Checksum Offset and Start - CSO and CSS

A *Checksum Offset (TDESC.CSO)* field indicates where, relative to the start of the packet, to insert a TCP checksum if this mode is enabled. A *Checksum Start (TDESC.CSS)* field indicates where to begin computing the checksum.

Both CSO and CSS are in units of bytes and must be in the range of data provided to the I350 in the descriptors. For short packets that are not padded by software, CSS and CSO must be in the range of the unpadded data length, not the eventual padded length (64 bytes).

CSO must be set to the location of TCP checksum in the packet. CSS must be set to the beginning of the IP header or the L4 (TCP) header. Checksum calculation is not done if CSO or CSS are out of range. This occurs if (CSS > length) OR (CSO > length - 1).

In the case of an 802.1Q header, the offset values depend on the VLAN insertion enable (VLE) bit. If it is not set (VLAN tagging included in the packet buffers), the offset values should include the VLAN tagging. If this bit is set (VLAN tagging is taken from the packet descriptor), the offset values should exclude the VLAN tagging.

**Note:** Assuming CSS points to the beginning of the IP header, software must compute an offsetting entry to back out the bytes of the header that are not part of the IP pseudo header and should not be included in the TCP checksum and store it in the position where the hardware computed checksum is to be inserted. Hardware does not add the 802.1Q Ethertype or the VLAN field following the 802.1Q Ethertype to the checksum. So for VLAN packets, software can compute the values to back out only the encapsulated IP header packet and not the added fields.

UDP checksum calculation is not supported by the legacy descriptors. When using legacy descriptors the I350 is not aware of the L4 type of the packet and thus, does not support the translation of a checksum result of 0x0000 to 0xFFFF needed to differentiate between an UDP packet with a checksum of zero and an UDP packet without checksum.

Because the CSO field is eight bits wide, it puts a limit on the location of the checksum to 255 bytes from the beginning of the packet.

Hardware adds the checksum to the field at the offset indicated by the CSO field. Checksum calculations are for the entire packet starting at the byte indicated by the CSS field. A value of zero corresponds to the first byte in the packet.

CSS must be set in the first descriptor of the packet.

**Table 7-26 Transmit Command (TDESC.CMD) Layout**

| 7   | 6   | 5    | 4   | 3  | 2  | 1    | 0   |
|-----|-----|------|-----|----|----|------|-----|
| RSV | VLE | DEXT | Rsv | RS | IC | IFCS | EOP |

#### 7.2.2.1.4 Command Byte - CMD

The CMD byte stores the applicable command and has the fields shown in [Figure 7-26](#).

- RSV (bit 7) - Reserved
- VLE (bit 6) - VLAN Insertion Enable (See [Table 7-27](#)).
- DEXT (bit 5) - Descriptor Extension (0 for legacy mode)
- Reserved (bit 4) - Reserved
- RS (bit 3) - Report Status
- IC (bit 2) - Insert Checksum
- IFCS (bit 1) - Insert FCS
- EOP (bit 0) - End of Packet

VLE: Indicates that the packet is a VLAN packet. For example, hardware should add the VLAN Ethertype and an 802.1q VLAN tag to the packet.

**Table 7-27 VLAN Tag Insertion Decision Table**

| VLE | Action                                                                            |
|-----|-----------------------------------------------------------------------------------|
| 0b  | Send generic Ethernet packet.                                                     |
| 1b  | Send 802.1Q packet; The VLAN data comes from the VLAN field of the TX descriptor. |

RS: Signals the hardware to report the status information. This is used by software that does in-memory checks of the transmit descriptors to determine which ones are done. For example, if software queues up 10 packets to transmit, it can set the RS bit in the last descriptor of the last packet. If software maintains a list of descriptors with the RS bit set, it can look at them to determine if all packets up to (and including) the one with the RS bit set have been buffered in the output FIFO. Looking at the status byte and checking the *Descriptor Done (DD)* bit enables this operation. If DD is set, the descriptor has been processed. Refer to [Table 7-28](#) for the layout of the status field.

IC: If set, requests hardware to add the checksum of the data from CSS to the end of the packet at the offset indicated by the CSO field.

IFCS: When set, hardware appends the MAC FCS at the end of the packet. When cleared, software should calculate the FCS for proper CRC check. There are several cases in which software must set IFCS:

- Transmitting a short packet while padding is enabled by the TCTL.PSP bit.
- Checksum offload is enabled by the IC bit in the TDESC.CMD.
- VLAN header insertion enabled by the VLE bit in the TDESC.CMD or by the VMVIR[n] registers.

EOP: When set, indicates this is the last descriptor making up the packet. Note that more than one descriptor can be used to form a packet.

**Note:** the 8257, 1VLE, IFCS, CSO, and IC must be set correctly only in the first descriptor of each packet. In previous silicon generations, some of these bits were required to be set in the last descriptor of a packet.

### 7.2.2.1.5 Status – STA

**Table 7-28 Transmit Status (TDESC.STA) Layout**

| 3        | 2 | 1 | 0  |
|----------|---|---|----|
| Reserved |   |   | DD |

### 7.2.2.1.6 DD (Bit 0) - Descriptor Done Status

The DD bit provides the transmit status, when RS is set in the command: DD indicates that the descriptor is done and is written back after the descriptor has been processed.

**Note:** When head write back is enabled (TDWBAL[n].Head\_WB\_En = 1), there is no write-back of the DD bit to the descriptor. When using legacy Tx descriptors, Head writeback should not be enabled (TDWBAL[n].Head\_WB\_En = 0).

### 7.2.2.1.7 VLAN

The *VLAN* field is used to provide the 802.1q/802.1ac tagging information. The *VLAN* field is valid only on the first descriptor of each packet when the *VLE* bit is set and the *VMVIR[n].VLANA* register field is 0. The rule for VLAN tag is to use network ordering. The VLAN field is placed in the transmit descriptor in the following manner:

**Table 7-29 VLAN Field (TDESC.VLAN) Layout**

|              |           |           |          |
|--------------|-----------|-----------|----------|
| <b>15 13</b> | <b>12</b> | <b>11</b> | <b>0</b> |
| PRI          | CFI       | VLAN ID   |          |

- VLAN ID - the 12-bit tag indicating the VLAN group of the packet.
- Canonical Form Indication (CFI) - Set to zero for Ethernet packets.
- PRI - indicates the priority of the packet.

**Note:** The VLAN tag is sent in network order (also called big endian).

## 7.2.2.2 Advanced Transmit Context Descriptor

**Table 7-30 Transmit Context Descriptor (TDESC) Layout - (Type = 0010b)**

|          |           |           |           |           |           |           |           |          |          |          |
|----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|----------|----------|----------|
|          | <b>63</b> | <b>40</b> | <b>39</b> | <b>32</b> | <b>31</b> | <b>16</b> | <b>15</b> | <b>9</b> | <b>8</b> | <b>0</b> |
| <b>0</b> | Reserved  |           | Reserved  |           | VLAN      |           | MACLEN    |          | IPLN     |          |

|          |           |           |           |           |                  |           |           |           |           |                  |           |           |           |           |           |          |          |          |
|----------|-----------|-----------|-----------|-----------|------------------|-----------|-----------|-----------|-----------|------------------|-----------|-----------|-----------|-----------|-----------|----------|----------|----------|
|          | <b>63</b> | <b>48</b> | <b>47</b> | <b>40</b> | <b>39</b>        | <b>38</b> | <b>36</b> | <b>35</b> | <b>30</b> | <b>29</b>        | <b>28</b> | <b>24</b> | <b>23</b> | <b>20</b> | <b>19</b> | <b>9</b> | <b>8</b> | <b>0</b> |
| <b>8</b> | MSS       |           | L4LEN     |           | RSV <sup>1</sup> | IDX       | Reserved  |           | DEXT      | RSV <sup>1</sup> | DTYP      |           | TUCMD     |           | Reserved  |          |          |          |

1. RSV - Reserved

### 7.2.2.2.1 IPLN (9)

IP header length. If an offload is requested, *IPLN* must be greater than or equal to 20 and less than or equal to 511.

### 7.2.2.2.2 MACLEN (7)

This field indicates the length of the MAC header. When an offload is requested (either *TSE* or *IXSM* or *TXSM* is set), *MACLEN* must be larger than or equal to 14 and less than or equal to 127. This field should include only the part of the L2 header supplied by the software device driver and not the parts added by hardware. The following table lists the value of *MACLEN* in the different cases.

**Table 7-31 MACLEN Values**

| <b>SNAP</b> | <b>Regular VLAN</b>    | <b>External VLAN</b> | <b>MACLEN</b> |
|-------------|------------------------|----------------------|---------------|
| No          | By hardware or no VLAN | No                   | 14            |
| No          | By hardware or no VLAN | Yes                  | 18            |
| No          | By software            | No                   | 18            |
| No          | By software            | Yes                  | 22            |
| Yes         | By hardware or no VLAN | No                   | 22            |
| Yes         | By hardware or no VLAN | Yes                  | 26            |

**Table 7-31 MACLEN Values (Continued)**

| SNAP | Regular VLAN | External VLAN | MACLEN |
|------|--------------|---------------|--------|
| Yes  | By software  | No            | 26     |
| Yes  | By software  | Yes           | 30     |

**VLAN (16)** - 802.1Q VLAN tag to be inserted in the packet during transmission. This VLAN tag is inserted and needed only when a packet using this context has its *DCMD.VLE* bit set and the *VMVIR[n].VLANA* register field is 0. This field should include the entire 16-bit VLAN field including the *CFI* and *Priority* fields as shown in [Table 7-29](#).

**Note:** The VLAN tag is sent in network order.

### 7.2.2.2.3 TUCMD (11)

**Table 7-32 Transmit Command (TDESC.TUCMD) Layout**

| 10       | 6        | 5        | 4        | 3   | 2    | 1    | 0 |
|----------|----------|----------|----------|-----|------|------|---|
| Reserved | Reserved | Reserved | Reserved | L4T | IPV4 | SNAP |   |

- RSV (bit 10:6) - Reserved
- RSV (bit 5:4) - Reserved
- L4T (bit 3:2) - L4 Packet TYPE (00b: UDP; 01b: TCP; 10b: SCTP; 11b: Reserved)
- IPV4 (bit 1) - IP Packet Type: When 1b, IPv4; when 0b, IPv6
- SNAP (bit 0) - SNAP indication

### 7.2.2.2.4 DTYP(4)

Always 0010b for this type of descriptor.

### 7.2.2.2.5 DEXT(1)

Descriptor Extension (1b for advanced mode).

### 7.2.2.2.6 IDX (3)

Index into the hardware context table where this context is stored. In the I350 the 2 available register context sets per queue are accessed using the LSB bit and the two MSB bits are reserved and should always be 0.

### 7.2.2.2.7 L4LEN (8)

Layer 4 header length. If *TSE* is set in the data descriptor pointing to this context, this field must be greater than or equal to 12 and less than or equal to 255. Otherwise, this field is ignored.

### 7.2.2.2.8 MSS (16)

Controls the Maximum Segment Size (MSS). This specifies the maximum TCP payload segment sent per frame, not including any header or trailer. The total length of each frame (or section) sent by the TCP/UDP segmentation mechanism (excluding Ethernet CRC) as follows:

Total length is equal to:

$$\text{MACLEN} + 4(\text{if VLAN is inserted}) + \text{IPLen} + \text{L4LEN} + \text{MSS}$$

A VLAN is inserted if VLE set and the VMVIR[n].VLANA register field is 00b or if VMVIR[n].VLANA register field is 01b.

The one exception is the last packet of a TCP/UDP segmentation, which is typically shorter.

MSS is ignored when *DCMD.TSE* is not set.

**Note:** The headers lengths must meet the following:

$$\text{MACLEN} + \text{IPLen} + \text{L4LEN} \leq 512$$

**Note:** The MSS value should be larger than 0 and the maximum MSS value should not exceed 9216 bytes (9KB) length.

The context descriptor requires valid data only in the fields used by the specific offload options. The following table lists the required valid fields according to the different offload options.

**Table 7-33 Valid Field in Context vs. Required Offload**

| Required Offload |      |                | Valid Fields in Context                |       |       |        |     |     |      |
|------------------|------|----------------|----------------------------------------|-------|-------|--------|-----|-----|------|
| TSE              | TXSM | IXSM           | VLAN <sup>1</sup>                      | L4LEN | IPLen | MACLEN | MSS | L4T | IPV4 |
| 1b <sup>2</sup>  | 1b   | X <sup>3</sup> | VLE                                    | Yes   | Yes   | Yes    | Yes | Yes | Yes  |
| 0b               | 1b   | X <sup>2</sup> | VLE                                    | No    | Yes   | Yes    | No  | Yes | Yes  |
| 0b               | 0b   | 1b             | VLE                                    | No    | Yes   | Yes    | No  | No  | Yes  |
| 0b               | 0b   | 0b             | No context required unless VLE is set. |       |       |        |     |     |      |

1. VLAN field is required only if VLE bit in TX Descriptor is set and the VMVIR[n].VLANA register field is 0.

2. If TSE is set, TXSM must be set to 1.

3. X - don't care

## 7.2.2.3 Advanced Transmit Data Descriptor

**Table 7-34 Advanced Transmit Data Descriptor (TDES) Layout - (Type = 0011b)**

|   |               |       |                  |     |       |       |       |       |                  |        |      |
|---|---------------|-------|------------------|-----|-------|-------|-------|-------|------------------|--------|------|
| 0 | Address[63:0] |       |                  |     |       |       |       |       |                  |        |      |
| 8 | PAYLEN        | POPTS | RSV <sup>1</sup> | IDX | STA   | DCMD  | DTYP  | MAC   | RSV <sup>1</sup> | DTALEN |      |
|   | 63            | 46    | 45 40            | 39  | 38 36 | 35 32 | 31 24 | 23 20 | 19 18            | 17 16  | 15 0 |

1. RSV - Reserved

**Table 7-35 Advanced Tx descriptor write-back format**

|   |                  |  |  |    |       |          |  |  |  |   |
|---|------------------|--|--|----|-------|----------|--|--|--|---|
| 0 | RSV <sup>1</sup> |  |  |    |       |          |  |  |  |   |
| 8 | Reserved         |  |  |    | STA   | Reserved |  |  |  |   |
|   | 63               |  |  | 36 | 35 32 | 31       |  |  |  | 0 |

1. RSV - Reserved

**Note:** For frames that span multiple descriptors, all fields **apart** from *DCMD.EOP*, *DCMD.RS*, *DCMD.DEXT*, *DTALEN*, Address and DTYP are valid only in the first descriptor and are ignored in the subsequent ones.

### 7.2.2.3.1 Address (64)

Physical address of a data buffer in host memory that contains a portion of a transmit packet.

### 7.2.2.3.2 DTALEN (16)

Length in bytes of data buffer at the address pointed to by this specific descriptor.

**Note:** If the *TCTL.PSP* bit is set, the total length of the packet transmitted, not including FCS, should be at least 17 bytes. If bit is cleared the total length of the packet transmitted, not including FCS should be at least 60 bytes.

The maximum allowable packet size for transmits is based on the value written to the *DMA TX Max Allowable packet size (DTXMPKTSZ)* register. Default value is 9,728 bytes.

### 7.2.2.3.3 MAC (2)

**Table 7-36 Transmit Data (TDES.MAC) Layout**

|      |          |
|------|----------|
| 1    | 0        |
| 1588 | Reserved |

- 1588 (bit 1) - IEEE1588 Timestamp packet.

### 7.2.2.3.4 DTYP (4)

0011b is the value for this descriptor type.

### 7.2.2.3.5 DCMD (8)

**Table 7-37 Transmit Data (TDES.DCMD) Layout**

| 7   | 6   | 5    | 4        | 3  | 2        | 1    | 0   |
|-----|-----|------|----------|----|----------|------|-----|
| TSE | VLE | DEXT | Reserved | RS | Reserved | IFCS | EOP |

- TSE (bit 7) - TCP/UDP Segmentation Enable
- VLE (bit 6) - VLAN Packet Enable
- DEXT (bit 5) - Descriptor Extension (1b for advanced mode)
- Reserved (bit 4)
- RS (bit 3) - Report Status
- Reserved (bit 2)
- IFCS (bit 1) - Insert FCS
- EOP (bit 0) - End Of Packet

*TSE* indicates a TCP/UDP segmentation request. When *TSE* is set in the first descriptor of a TCP packet, hardware must use the corresponding context descriptor in order to perform TCP segmentation. The type of segmentation applied is defined according to the *TUCMD.L4T* field in the context descriptor.

**Note:** It is recommended that *TCTL.PSP* be enabled when *TSE* is used since the last frame can be shorter than 60 bytes - resulting in a bad frame if *TCTL.PSP* is disabled.

*VLE* indicates that the packet is a VLAN packet and hardware must add the VLAN Ethertype and an 802.1q VLAN tag to the packet if the *VMVIR[n].VLANA* register field is 0.

**Note:** If *VLE* is set when the *VMVIR[n].VLANA* register field is not 0 the packet will be dropped.

*DEXT* must be 1b to indicate advanced descriptor format (as opposed to legacy).

*RS* signals hardware to report the status information. This is used by software that does in-memory checks of the transmit descriptors to determine which ones are done. For example, if software queues up 10 packets to transmit, it can set the *RS* bit in the last descriptor of the last packet. If software maintains a list of descriptors with the *RS* bit set, it can look at them to determine if all packets up to (and including) the one with the *RS* bit set have been buffered in the output FIFO. Looking at the status byte and checking the *DD* bit do this. If *DD* is set, the descriptor has been processed. Refer to the next section for the layout of the status field.

**Note:** Descriptors with zero length transfer no data.

*IFCS*, when set, hardware appends the MAC FCS at the end of the packet. When cleared, software should calculate the FCS for proper CRC check. There are several cases in which the hardware changes the packet, and thus the software must set *IFCS*:

- Transmitting a short packet while padding is enabled by the *TCTL.PSP* bit.
- Checksum offload is enabled by either the *TXSM* or *IXSM* bits in the *TDES.POPTS* field.
- VLAN header insertion enabled by the *VLE* bit in the *TDES.DCMD* descriptor field when the *VMVIR[n].VLANA* register field is 0.
- TCP/UDP segmentation offload enabled by *TSE* bit in the *TDES.DCMD*.

*EOP* indicates whether this is the last buffer for an incoming packet.

### 7.2.2.3.6 STA (4)

- Rsv (bits 1-3) - Reserved
- DD (bit 0) - Descriptor Done

### 7.2.2.3.7 ID<sub>X</sub> (3)

Index into the hardware context table to indicate which context should be used for this request. If no offload is required, this field is not relevant and no context needs to be initiated before the packet is sent. See Table 7-33 for details on type of transmit packet offloads that require a context reference.

### 7.2.2.3.8 POPTS (6)

**Table 7-38 Transmit Data (TDES<sub>D</sub>.POPTS) Layout**

| 5        | 3        | 2    | 1    | 0 |
|----------|----------|------|------|---|
| Reserved | Reserved | TXSM | IXSM |   |

- Reserved (bits 5:3)
- Reserved (bit 2)
- TXSM (bit 1) - Insert L4 Checksum
- IXSM (bit 0) - Insert IP Checksum

TXSM, when set to 1b, L4 checksum must be inserted. In this case, TUCMD.L4T in the context descriptor indicates whether the checksum is TCP, UDP, or SCTP.

When DCMD.TSE in TDES<sub>D</sub> is set, TXSM must be set to 1b.

If this bit is set, the packet should at least contain a TCP header.

IXSM, when set to 1b, indicates that IP checksum must be inserted. For IPv6 packets this bit must be cleared.

If the DCMD.TSE bit is set in data descriptor, and TUCMD.IPV4 is set in context descriptor, POPTS.IXSM must be set to 1b as well.

If this bit is set, the packet should at least contain an IP header.

### 7.2.2.3.9 PAYLEN (18)

PAYLEN indicates the size (in byte units) of the data buffer(s) in host memory for transmission. In a single send packet, PAYLEN defines the entire packet size fetched from host memory. It does not include the fields that hardware adds such as: optional VLAN tagging, Ethernet CRC or Ethernet padding. When TCP or UDP segmentation offload is enabled (DCMD.TSE is set), PAYLEN defines the TCP/UDP payload size fetched from host memory.

**Note:** When a packet spreads over multiple descriptors, all the descriptor fields are only valid in the first descriptor of the packet, except for RS, which is always checked, DTALLEN that reflects the size of the buffer in the current descriptor and EOP, which is always set at last descriptor of the series.

## 7.2.2.4 Transmit Descriptor Ring Structure

The transmit descriptor ring structure is shown in Figure 7-11. A set of hardware registers maintains each transmit descriptor ring in the host memory. New descriptors are added to the queue by software by writing descriptors into the circular buffer memory region and moving the tail pointer associated with that queue. The tail pointer points to one entry beyond the last hardware owned descriptor. Transmission continues up to the descriptor where head equals tail at which point the queue is empty.

Descriptors passed to hardware should not be manipulated by software until the head pointer has advanced past them.

**Figure 7-11 Transmit Descriptor Ring Structure**

The shaded boxes in the figure represent descriptors that are not currently owned by hardware that software can modify.

The transmit descriptor ring is described by the following registers:

- **Transmit Descriptor Base Address register (TDBA 0-7):**  
This register indicates the start address of the descriptor ring buffer in the host memory; this 64-bit address is aligned on a 16-byte boundary and is stored in two consecutive 32-bit registers. Hardware ignores the lower four bits.
- **Transmit Descriptor Length register (TDLEN 0-7):**  
This register determines the number of bytes allocated to the circular buffer. This value must be zero modulo 128.
- **Transmit Descriptor Head register (TDH 0-7):**  
This register holds a value that is an offset from the base and indicates the in-progress descriptor. There can be up to 64 KB descriptors in the circular buffer. Reading this register returns the value of head corresponding to descriptors already loaded in the output FIFO. This register reflects the internal head of the hardware write-back process including the descriptor in the posted write pipe and might point further ahead than the last descriptor actually written back to the memory.
- **Transmit Descriptor Tail register (TDT 0-7):**

This register holds a value, which is an offset from the base, and indicates the location beyond the last descriptor hardware can process. This is the location where software writes the first new descriptor.

The driver should not handle to the I350 descriptors that describe a partial packet. Consequently, the number of descriptors used to describe a packet can not be larger than the ring size.

- **Tx Descriptor Completion Write-Back Address High/Low Registers (*TDWBAH/TDWBAL* 0-7):**  
These registers hold a value that can be used to enable operation of head writeback operation. When *TDWBAL.Head\_WB\_En* is set and the RS bit is set in the Tx descriptor, following corresponding data upload into packet buffer, the I350 writes the Transmit Descriptor Head value for this queue to the 64 bit address specified by the *TDWBAH* and *TDWBAL* registers. The Descriptor Head value is an offset from the base, and indicates the descriptor location hardware processed and software can utilize for new Transmit packets. See [Section 7.2.3](#) for additional information.

The base register indicates the start of the circular descriptor queue and the length register indicates the maximum size of the descriptor ring. The lower seven bits of length are hard wired to 0b. Byte addresses within the descriptor buffer are computed as follows:  $\text{address} = \text{base} + (\text{ptr} * 16)$ , where ptr is the value in the hardware head or tail register.

The size chosen for the head and tail registers permit a maximum of 65536 (64 KB) descriptors, or approximately 16 KB packets for the transmit queue given an average of four descriptors per packet.

Once activated, hardware fetches the descriptor indicated by the hardware head register. The hardware tail register points one descriptor beyond the last valid descriptor. Software can read and detect which packets have already been processed by hardware as follows:

- Read the head register to determine which packets (those logically before the head) have been transferred to the on-chip FIFO or transmitted. Note that this method is not recommended as races between the internal update of the head register and the actual write-back of descriptors might occur.
- Read the value of the head as stored at the address pointed by the *TDWBAH/TDWBAL* pair.
- Track the *DD* bits in the descriptor ring.

All the registers controlling the descriptor rings behavior should be set before transmit is enabled, apart from the tail registers which are used during the regular flow of data.

**Note:** Software can determine if a packet has been sent by either of three methods: setting the RS bit in the transmit descriptor command field or by performing a PIO read of the transmit head register, or by reading the head value written by the I350 to the address pointed by the *TDWBAL* and *TDWBAH* registers (see [Section 7.2.3](#) for details). Checking the transmit descriptor *DD* bit or head value in memory eliminates a potential race condition. All descriptor data is written to the I/O bus prior to incrementing the head register, but a read of the head register could pass the data write in systems performing I/O write buffering. Updates to transmit descriptors use the same I/O write path and follow all data writes. Consequently, they are not subject to the race.

In general, hardware prefetches packet data prior to transmission. Hardware typically updates the value of the head pointer after storing data in the transmit FIFO.

### 7.2.2.5 Transmit Descriptor Fetching

When the *TXDCTL[n].ENABLE* bit is set and the on-chip descriptor cache is empty, a fetch happens as soon as any descriptors are made available (Host increments the *TDT[n]* tail pointer). The descriptor processing strategy for transmit descriptors is essentially the same as for receive descriptors except that a different set of thresholds are used. The number of on-chip transmit descriptors per queue is 24. When there is an on-chip descriptor buffer empty, a descriptor fetch happens as soon as any

descriptors are made available (host writes to the tail pointer). If several on-chip transmit descriptor queues need to fetch descriptors, descriptors from queues that are more starved are fetched. If a number of queues have a similar starvation level, highest indexed queue is served first and so forth, down to the lowest indexed queue.

**Note:** The starvation level of a queue corresponds to the number of descriptors above the prefetch threshold ( $TXDCTL[n].PTHRESH$ ) that are already in the internal queue. The queue is more starved if there are less descriptors in the internal transmit descriptor cache. Comparing starvation level might be done roughly, not at the single descriptor level of resolution.

A queue is considered empty for the transmit descriptor fetch algorithm as long as:

- There is still no complete packet (single or large send) in its corresponding internal queue.
- There is no descriptor already in its way from system memory to the internal cache.
- The internal corresponding internal descriptor cache is not full.

Each time a descriptor fetch request is sent for an empty queue, the maximum available number of descriptor is requested, regardless of cache alignment issues.

When the on-chip buffer is nearly empty (below  $TXDCTL[n].PTHRESH$ ), a prefetch is performed each time enough valid descriptors ( $TXDCTL[n].HTHRESH$ ) are available in host memory and no other DMA activity of greater priority is pending (descriptor fetches and write-backs or packet data transfers).

When the number of descriptors in host memory is greater than the available on-chip descriptor storage, the I350 might elect to perform a fetch that is not a multiple of cache-line size. Hardware performs this non-aligned fetch if doing so results in the next descriptor fetch being aligned on a cache-line boundary. This enables the descriptor fetch mechanism to be more efficient in the cases where it has fallen behind software.

**Note:** The I350 NEVER fetches descriptors beyond the descriptor tail pointer.

### 7.2.2.6 Transmit Descriptor Write-Back

The descriptor write-back policy for transmit descriptors is similar to that of the receive descriptors when the  $TXDCTL[n].WTHRESH$  value is not 0x0. In this case, all descriptors are written back regardless of the value of their *RS* bit.

When the  $TXDCTL[n].WTHRESH$  value is 0x0, since transmit descriptor write-backs do not happen for every descriptor, only transmit descriptors that have the *RS* bit set are written back.

Any descriptor write-back includes the full 16 bytes of the descriptor.

Since the benefit of delaying and then bursting transmit descriptor write-backs is small at best, it is likely that the threshold is left at the default value (0x0) to force immediate write-back of transmit descriptors with their *RS* bit set and to preserve backward compatibility.

Descriptors are written back in one of three cases:

- $TXDCTL[n].WTHRESH = 0x0$  and a descriptor which has *RS* set is ready to be written back.
- The corresponding *EITR* counter has reached zero.
- $TXDCTL[n].WTHRESH > 0x0$  and  $TXDCTL[n].WTHRESH$  descriptors have accumulated.

For the first condition, write-backs are immediate. This is the default operation and is backward compatible with previous device implementations.

The other two conditions are only valid if descriptor bursting is enabled ([Section 8.12.15](#)). In the second condition, the *EITR* counter is used to force timely write-back of descriptors. The first packet after timer initialization starts the timer. Timer expiration flushes any accumulated descriptors and sets an interrupt event (*TXDW*).

For the last condition, if *TXDCTL[n].WTHRESH* descriptors are ready for write-back, the write-back is performed.

An additional mode in which transmit descriptors are not written back at all and the head pointer of the descriptor ring is written instead as described in [Section 7.2.3](#).

**Note:** When transmit ring is smaller than internal cache size (24 descriptors) then at least one full packet should be placed in the ring and *TXDCTL[n].WTHRESH* value should be less than ring size. If *TXDCTL[n].WTHRESH* is 0x0 (transmit RS mode) then at least one descriptor should have the RS bit set inside the ring.

## 7.2.3 Transmit Completions Head Write Back

In legacy hardware, transmit requests are completed by writing the *DD* bit to the transmit descriptor ring. This causes cache thrash since both the software device driver and hardware are writing to the descriptor ring in host memory. Instead of writing the *DD* bits to signal that a transmit request completed, hardware can write the contents of the descriptor queue head to host memory. The software device driver reads that memory location to determine which transmit requests are complete. In order to improve the performance of this feature, the software device driver may program DCA registers to configure which CPU is processing each TX queue to allow pre-fetching of the head write back value from the right cache.

### 7.2.3.1 Description

The head counter is reflected in a memory location that is allocated by software, for each queue.

Head write back occurs if *TDWBAL[n].Head\_WB\_En* is set for this queue and the *RS* bit is set in the Tx descriptor, following corresponding data upload into packet buffer. If the head write-back feature is enabled, the I350 ignores *TXDCTL[n].WTHRESH* and takes in account only descriptors with the *RS* bit set (as if the *TXDCTL[n].WTHRESH* field was set to 0x0). In addition, the head write-back occurs upon *EITR* expiration for queues where the *WB\_on\_EITR* bit in *TDWBAL[n]* is set.

Software can also enable coalescing of the head write-back operations to reduce traffic on the PCIe bus, by programming the *TXDCTL.HWBTHRESH* field to a value greater than 0. In this case head write-back operation will occur only after the internal pending write-back count is greater than the *TXDCTL[n].HWBTHRESH* value.

The software device driver has control on this feature through Tx queue 0-7 head write-back address, low (*TDWBAL[n]*) and high (*TDWBAH[n]*) registers thus supporting 64-bit address access. See registers description in [Section 8.12.16](#) and [Section 8.12.17](#).

The 2 low register's LSB bits of the *TDWBAL[n]* register hold the control bits.

1. The *Head\_WB\_En* bit enables activation of the head write back feature. When *TDWBAL[n].Head\_WB\_En* is set to 1 no TX descriptor write-back is executed for this queue.
2. The *WB\_on\_EITR* bit enables head write upon *EITR* expiration. When Head write back operation is enabled (*TDWBAL[n].Head\_WB\_En* = 1) setting the *TDWBAL[n].WB\_on\_EITR* bit to 1 enables placing an upper limit on delay of head write-back operation.

The 30 upper bits of the *TDWBAL[n]* register hold the lowest 32 bits of the head write-back address, assuming that the two last bits are zero. The *TDWBAH[n]* register holds the high part of the 64-bit address.

**Note:** Hardware writes a full Dword when writing this value, so software should reserve enough space for each head value.

If software enables Head Write-Back, it must also disable PCI Express Relaxed Ordering on the write-back transactions. This is done by disabling bit 11 in the *TXCTL* register for each active transmit queue. See [Section 8.13.2](#).

The I350 might update the Head with values that are larger than the last Head pointer which holds a descriptor with RS bit set, but still the value will always point to a free descriptor (descriptor that is not owned by the I350 anymore).

**Note:** Software should program *TDWBAL[n]*, *TDWBAH[n]* registers when queue is disabled (*TXDCTL[n].Enable* = 0).

## 7.2.4 TCP/UDP Segmentation

Hardware TCP segmentation is one of the offloading options supported by the Windows\* and Linux\* TCP/IP stack. This is often referred to as TCP Segmentation Offloading or TSO. This feature enables the TCP/IP stack to pass to the network device driver a message to be transmitted that is bigger than the Maximum Transmission Unit (MTU) of medium. It is then the responsibility of the software device driver and hardware to divide the TCP message into MTU size frames that have appropriate layer 2 (Ethernet), 3 (IP), and 4 (TCP) headers. These headers must include sequence number, checksum fields, options and flag values as required. Note that some of these values (such as the checksum values) are unique for each packet of the TCP message and other fields such as the source IP address are constant for all packets associated with the TCP message.

The I350 supports also UDP segmentation for embedded applications, although this offload is not supported by the regular Windows\* and Linux\* stacks. Any reference in this section to TCP segmentation, should be considered as referring to both TCP and UDP segmentation.

Padding (TCTL.PSP) must be enabled in TCP segmentation mode, since the last frame might be shorter than 60 bytes, resulting in a bad frame if *PSP* is disabled.

The offloading of these mechanisms from the software device driver to the I350 saves significant CPU cycles. Note that the software device driver shares the additional tasks to support these options.

### 7.2.4.1 Assumptions

The following assumptions apply to the TCP segmentation implementation in the I350:

- The *RS* bit operation is not changed.
- Interrupts are set after data in buffers pointed to by individual descriptors is transferred (DMA'd) to hardware.

### 7.2.4.2 Transmission Process

The transmission process for regular (non-TCP segmentation packets) involves:

- The protocol stack receives from an application a block of data that is to be transmitted.

- The protocol stack calculates the number of packets required to transmit this block based on the MTU size of the media and required packet headers.

For each packet of the data block:

- Ethernet, IP and TCP/UDP headers are prepared by the stack.
- The stack interfaces with the software device driver and commands it to send the individual packet.
- The software device driver gets the frame and interfaces with the hardware.
- The hardware reads the packet from host memory (via DMA transfers).
- The software device driver returns ownership of the packet to the Network Operating System (NOS) when hardware has completed the DMA transfer of the frame (indicated by an interrupt).

The transmission process for the I350 TCP segmentation offload implementation involves:

- The protocol stack receives from an application a block of data that is to be transmitted.
- The stack interfaces to the software device driver and passes the block down with the appropriate header information.
- The software device driver sets up the interface to the hardware (via descriptors) for the TCP segmentation context.

Hardware DMA's (transfers) the packet data and performs the Ethernet packet segmentation and transmission based on offset and payload length parameters in the TCP/IP context descriptor including:

- Packet encapsulation
- Header generation and field updates including IPv4, IPV6, and TCP/UDP checksum generation
- The software device driver returns ownership of the block of data to the NOS when hardware has completed the DMA transfer of the entire data block (indicated by an interrupt).

#### 7.2.4.2.1 TCP Segmentation Data Fetch Control

To perform TCP Segmentation in the I350, the DMA must be able to fit at least one packet of the segmented payload into available space in the on-chip Packet Buffer. The DMA does various comparisons between the remaining payload and the Packet Buffer available space, fetching additional payload and sending additional packets as space permits.

To support interleaving between descriptor queues at Ethernet frame resolution inside TSO requests, the frame header pointed to by the so called header descriptors are reread from system memory by hardware for every LSO segment. The I350 stores in an internal cache only the header's descriptors instead of the header's content.

To limit the internal cache size software should not spread the L3/L4 header (TCP, UDP, IPV4 or IPV6) on more than 4 descriptors. In the last header buffer it's allowed to mix header and data. This limitation stands for up to Layer4 header included, and for IPv4 or IPv6 indifferently.

#### 7.2.4.2.2 TCP Segmentation Write-Back Modes

Since the TCP segmentation mode uses the buffers that contains the L3/L4 header multiple times, there are some limitations on the usage of different combinations of writeback and buffer release methods in order to guarantee the header buffer's availability until the entire packet is processed. These limitations are described in [Table 7-39](#) below.

**Table 7-39 Write Back Options For Large Send**

| WTHRESH    | RS                          | HEAD Write Back Enable | Hardware Behavior                                                                                                                   | Software Expected Behavior for TSO packets.                                                                                                                                                                   |
|------------|-----------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | Set in EOP descriptors only | Disable                | Hardware writes back descriptors with RS bit set one at a time.                                                                     | Software can retake ownership of all descriptors up to last descriptor with DD bit set.                                                                                                                       |
| 0          | Set in any descriptors      | Disable                | Hardware writes back descriptors with RS bit set one at a time.                                                                     | Software can retake ownership of entire packets (EOP bit set) up to last descriptor with DD bit set.                                                                                                          |
| 0          | Not set at all              | Disable                | Hardware does not write back any descriptor (since RS bit is not set)                                                               | Software should poll the TDH register. The TDH register reflects the last descriptor that software can take ownership of. <sup>1</sup>                                                                        |
| 0          | Not set at all              | Enable                 | Hardware writes back the head pointer only at EITR expire event reflecting the last descriptor that software can take ownership of. | Software may poll the TDH register or use the head value written back at EITR expire event. The TDH register reflects the last descriptor that software can take ownership of.                                |
| >0         | Don't care                  | Disable                | Hardware writes back all the descriptors in bursts and set all the DD bits.                                                         | Software can retake ownership of entire packets up to last descriptor with both DD and EOP bits set.<br>Note: The TDH register reflects the last descriptor that software can take ownership of. <sup>1</sup> |
| Don't care | Set in EOP descriptors only | Enable                 | Hardware writes back the Head pointer per each descriptor with RS bit set. <sup>2</sup>                                             | Software can retake ownership of all descriptors up to the descriptor pointed by the head pointer read from system memory (by interrupt or polling).                                                          |
| Don't care | Set in any descriptors      | Enable                 | Hardware writes back the Head pointer per each descriptor with RS bit set.                                                          | This mode is illegal since software won't access the descriptor, it cannot tell when the pointer passed the EOP descriptor.                                                                                   |

1. Note that polling of the TDH register is a valid method only when the RS bit is never set, otherwise race conditions between software and hardware accesses to the descriptor ring can occur.

2. At EITR expire event, the Hardware writes back the head pointer reflecting the last descriptor that software can take ownership of.

### 7.2.4.3 TCP Segmentation Performance

Performance improvements for a hardware implementation of TCP Segmentation off-load include:

- The stack does not need to partition the block to fit the MTU size, saving CPU cycles.
- The stack only computes one Ethernet, IP, and TCP header per segment, saving CPU cycles.
- The Stack interfaces with the device driver only once per block transfer, instead of once per frame.
- Larger PCIe bursts are used which improves bus efficiency (such as lowering transaction overhead).
- Interrupts are easily reduced to one per TCP message instead of one per packet.
- Fewer I/O accesses are required to command the hardware.

### 7.2.4.4 Packet Format

Typical TCP/IP transmit window size is 8760 bytes (about 6 full size frames). Today the average size on corporate Intranets is 12-14KB, and normally the maximum window size allowed is 64KB (unless Windows Scaling - RFC 1323 is used). A TCP message can be as large as 256 KB and is generally fragmented across multiple pages in host memory. The I350 partitions the data packet into standard Ethernet frames prior to transmission according to the requested MSS. The I350 supports calculating the Ethernet, IP, TCP, and UDP headers, including checksum, on a frame-by-frame basis.

**Table 7-40 TCP/IP or UDP/IP Packet Format Sent by Host**

| L2/L3/L4 Header |           |         | Data                    |
|-----------------|-----------|---------|-------------------------|
| Ethernet        | IPv4/IPv6 | TCP/UDP | DATA (full TCP message) |

**Table 7-41 TCP/IP or UDP/IP Packet Format Sent by the I350**

|                           |                  |     |     |                           |                 |     |     |
|---------------------------|------------------|-----|-----|---------------------------|-----------------|-----|-----|
| L2/L3/L4 Header (updated) | Data (first MSS) | FCS | ... | L2/L3/L4 Header (updated) | Data (Next MSS) | FCS | ... |
|---------------------------|------------------|-----|-----|---------------------------|-----------------|-----|-----|

Frame formats supported by the I350 include:

- Ethernet 802.3
- IEEE 802.1Q VLAN (Ethernet 802.3ac)
- Ethernet Type 2
- Ethernet SNAP
- IPv4 headers with options
- IPv6 headers with extensions
- TCP with options
- UDP with options.

VLAN tag insertion might be handled by hardware

**Note:** UDP (unlike TCP) is not a “reliable protocol”, and fragmentation is not supported at the UDP level. UDP messages that are larger than the MTU size of the given network medium are normally fragmented at the IP layer. This is different from TCP, where large TCP messages can be fragmented at either the IP or TCP layers depending on the software implementation. The I350 has the ability to segment UDP traffic (in addition to TCP traffic), however, because UDP packets are generally fragmented at the IP layer, the I350’s “TCP Segmentation” feature is not normally useful to handle UDP traffic.

## 7.2.4.5 TCP/UDP Segmentation Indication

Software indicates a TCP/UDP Segmentation transmission context to the hardware by setting up a TCP/IP Context Transmit Descriptor (see [Section 7.2.2](#)). The purpose of this descriptor is to provide information to the hardware to be used during the TCP segmentation off-load process.

Setting the *TSE* bit in the *TDESD.DCMD* field to 1b indicates that this descriptor refers to the TCP Segmentation context (as opposed to the normal checksum off loading context). This causes the checksum off loading, packet length, header length, and maximum segment size parameters to be loaded from the Context descriptor into the device.

The TCP Segmentation prototype header is taken from the packet data itself. Software must identify the type of packet that is being sent (IPv4/IPv6, TCP/UDP, other), calculate appropriate checksum off loading values for the desired checksum, and calculate the length of the header which is pre-appended. The header might be up to 240 bytes in length.

Once the TCP Segmentation context has been set, the next descriptor provides the initial data to transfer. This first descriptor(s) must point to a packet of the type indicated. Furthermore, the data it points to might need to be modified by software as it serves as the prototype header for all packets

within the TCP Segmentation context. The following sections describe the supported packet types and the various updates which are performed by hardware. This should be used as a guide to determine what must be modified in the original packet header to make it a suitable prototype header.

The following summarizes the fields considered by the driver for modification in constructing the prototype header.

#### IP Header

For IPv4 headers:

- *Identification* Field should be set as appropriate for first packet to be sent
- Header Checksum should be zeroed out unless some adjustment is needed by the driver

#### TCP Header

- Sequence Number should be set as appropriate for first packet of send (if not already)
- PSH, and FIN flags should be set as appropriate for LAST packet of send
- TCP Checksum should be set to the partial pseudo-header sum as follows (there is a more detailed discussion of this in [Section 7.2.4.6](#)):

**Table 7-42 TCP Partial Pseudo-Header Sum for IPv4**

|                        |                     |      |
|------------------------|---------------------|------|
| IP Source Address      |                     |      |
| IP Destination Address |                     |      |
| Zero                   | Layer 4 Protocol ID | Zero |

**Table 7-43 TCP Partial Pseudo-Header Sum for IPv6**

|                                |             |
|--------------------------------|-------------|
| IPv6 Source Address            |             |
| IPv6 Final Destination Address |             |
| Zero                           |             |
| Zero                           | Next Header |

#### UDP Header

- Checksum should be set as in TCP header, above

The following sections describe the updating process performed by the hardware for each frame sent using the TCP Segmentation capability.

### 7.2.4.6 Transmit Checksum Offloading with TCP/UDP Segmentation

The I350 supports checksum off-loading as a component of the TCP Segmentation off-load feature and as a standalone capability. [Section 7.2.5](#) describes the interface for controlling the checksum off-loading feature. This section describes the feature as it relates to TCP Segmentation.

The I350 supports IP and TCP header options in the checksum computation for packets that are derived from the TCP Segmentation feature.

**Note:** The I350 is capable of computing one level of IP header checksum and one TCP/UDP header and payload checksum. In case of multiple IP headers, the driver needs to compute all but

one IP header checksum. The I350 calculates check sums on the fly on a frame-by-frame basis and inserts the result in the IP/TCP/UDP headers of each frame. TCP and UDP checksum are a result of performing the checksum on all bytes of the payload and the pseudo header.

Two specific types of checksum are supported by the hardware in the context of the TCP Segmentation off-load feature:

- IPv4 checksum
- TCP checksum
- See [Section 7.2.5](#) for description of checksum off loading of a single-send packet.

Each packet that is sent via the TCP segmentation off-load feature optionally includes the IPv4 checksum and either the TCP checksum.

All checksum calculations use a 16-bit wide one's complement checksum. The checksum word is calculated on the outgoing data.

**Table 7-44 Supported Transmit Checksum Capabilities**

| Packet Type                                                               | Hardware IP Checksum Calculation | Hardware TCP/UDP Checksum Calculation |
|---------------------------------------------------------------------------|----------------------------------|---------------------------------------|
| IP v4 packets                                                             | Yes                              | Yes                                   |
| IP v6 packets<br>(no IP checksum in IPv6)                                 | NA                               | Yes                                   |
| Packet is greater than 1518, 1522 or 1526 bytes;<br>(LPE=1b) <sup>1</sup> | Yes                              | Yes                                   |
| Packet has 802.3ac tag                                                    | Yes                              | Yes                                   |
| Packet has IP options<br>(IP header is longer than 20 bytes)              | Yes                              | Yes                                   |
| Packet has TCP or UDP options                                             | Yes                              | Yes                                   |
| IP header's protocol field contains a protocol # other than TCP or UDP.   | Yes                              | No                                    |

1. Depends on number of VLAN tags.

The table below summarizes the conditions of when checksum off loading can/should be calculated.

**Table 7-45 Conditions for Checksum Off Loading**

| Packet Type | IPv4 | TCP/UDP | Reason                                             |
|-------------|------|---------|----------------------------------------------------|
| Non TSO     | Yes  | No      | IP Raw packet (non TCP/UDP protocol)               |
|             | Yes  | Yes     | TCP segment or UDP datagram with checksum off-load |
|             | No   | No      | Non-IP packet or checksum not offloaded            |
| TSO         | Yes  | Yes     | For TSO, checksum off-load must be done            |

## 7.2.4.7 TCP/UDP/IP Headers Update

IP/TCP or IP/UDP header is updated for each outgoing frame based on the IP/TCP header prototype which hardware DMA's from the first descriptor(s). The checksum fields and other header information are later updated on a frame-by-frame basis. The updating process is performed concurrently with the packet data fetch.

The following sections define what fields are modified by hardware during the TCP Segmentation process by the I350.

**Note:** Placing incorrect values in the Context descriptors may cause failure of Large Send. The indication of Large Send failure can be checked in the *TSC TC* statistics register.

#### 7.2.4.7.1 TCP/UDP/IP Headers for the First Frames

The hardware makes the following changes to the headers of the first packet that is derived from each TCP segmentation context.

##### MAC Header (for SNAP)

- Type/Len field =  $MSS + MACLEN + IPLEN + L4LEN - 14 - 4$  (if VLAN added by Software)

##### IPv4 Header

- IP Identification: Value in the IPv4 header of the prototype header in the packet data itself
- IP Total Length =  $MSS + L4LEN + IPLEN$
- IP Checksum

##### IPv6 Header

- Payload Length =  $MSS + L4LEN + IPV6\_HDR\_extension^1$

##### TCP Header

- Sequence Number: The value is the Sequence Number of the first TCP byte in this frame.
- The flag values of the first frame are set by ANDing the flag word in the pseudo header with the *DTXTCPFLGL.TCP\_flg\_first\_seg* register field. The default value of the *DTXTCPFLGL.TCP\_flg\_first\_seg* are set so that the FIN flag and the PSH flag are cleared in the first frame.
- TCP Checksum

##### UDP Header

- UDP Length =  $MSS + L4LEN$
- UDP Checksum

#### 7.2.4.7.2 TCP/UDP/IP Headers for the Subsequent Frames

The hardware makes the following changes to the headers for subsequent packets that are derived as part of a TCP segmentation context:

Number of bytes left for transmission =  $PAYLEN - (N * MSS)$ . Where N is the number of frames that have been transmitted.

##### MAC Header (for SNAP Packets)

Type/Len field =  $MSS + MACLEN + IPLEN + L4LEN - 14 - 4$  (if VLAN added by Software)

##### IPv4 Header

- IP Identification: incremented from last value (wrap around based on 16 bit-width)
- IP Total Length =  $MSS + L4LEN + IPLEN$

---

1. *IPV6\_HDR\_extension* is calculated as  $IPLEN - 40$  bytes.

- IP Checksum

#### IPv6 Header

- Payload Length =  $MSS + L4LEN + \text{IPV6\_HDR\_extension}^1$

#### TCP Header

- Sequence Number update: Add previous TCP payload size to the previous sequence number value. This is equivalent to adding the *MSS* to the previous sequence number.
- The flag values of the subsequent frames are set by ANDing the flag word in the pseudo header with the *DTXTCPLGL.TCP\_Flg\_mid\_seg* register field. The default value of the *DTXTCPLGL.TCP\_Flg\_mid\_seg* are set so that if the FIN flag and the PSH flag are cleared in these frames.
- TCP Checksum

#### UDP Header

- UDP Length =  $MSS + L4LEN$
- UDP Checksum

### 7.2.4.7.3 TCP/UDP/IP Headers for the Last Frame

The hardware makes the following changes to the headers for the last frame of a TCP segmentation context:

Last frame payload bytes =  $PAYLEN - (N * MSS)$

#### MAC Header (for SNAP Packets)

- Type/Len field = Last frame payload bytes +  $MACLEN + IPLEN + L4LEN - 14 - 4$  (if VLAN added by Software)

#### IPv4 Header

- IP Total Length = last frame payload bytes +  $L4LEN + IPLEN$
- IP Identification: incremented from last value (wrap around based on 16 bit-width)
- IP Checksum

#### IPv6 Header

- Payload Length = last frame payload bytes +  $L4LEN + \text{IPV6\_HDR\_extension}^1$

#### TCP Header

- Sequence Number update: Add previous TCP payload size to the previous sequence number value. This is equivalent to adding the *MSS* to the previous sequence number.
- The flag values of the last frames are set by ANDing the flag word in the pseudo header with the *DTXTCPLGH.TCP\_Flg\_1st\_seg* register field. The default value of the *DTXTCPLGH.TCP\_Flg\_1st\_seg* are set so that if the FIN flag and the PSH flag are set in the last frame.
- TCP Checksum

#### UDP Header

- UDP Length = Last frame payload bytes +  $L4LEN$
- UDP Checksum

---

1. *IPV6\_HDR\_extension* is calculated as  $IPLEN - 40$  bytes.

### 7.2.4.8 Data Flow

The flow used by the I350 to do TCP segmentation is as follows:

1. Get a descriptor with a request for a TSO off-load of a TCP packet.
2. First Segment processing:
  - a. Fetch all the buffers containing the header as calculated by the *MACLEN*, *IPLLEN* and *L4LEN* fields. Save the addresses and lengths of the buffers containing the header (up to 4 buffers). The header content is not saved.
  - b. Fetch data up to the MSS from subsequent buffers & calculate the adequate checksum(s).
  - c. Update the Header accordingly and update internal state of the packet (next data to fetch and TCP SN).
  - d. Send the packet to the network.
  - e. If total packet was sent, go to step 4. else continue.
3. Next segments:
  - a. Wait for next arbitration of this queue.
  - b. Fetch all the buffers containing the header from the saved addresses. Subsequent reads of the header might be done with a no snoop attribute.
  - c. Fetch data up to the MSS or end of packet from subsequent buffers & calculate the adequate checksum(s).
  - d. Update the Header accordingly and update internal state of the packet (next data to fetch and TCP SN).
  - e. If total packet was sent, request is done, else restart from step 3.
4. Release all buffers (update head pointer).

**Note:** Descriptors are fetched in a parallel process according to the consumption of the buffers.

## 7.2.5 Checksum Offloading in Non-Segmentation Mode

The previous section on TCP Segmentation off-load describes the IP/TCP/UDP checksum off loading mechanism used in conjunction with TCP Segmentation. The same underlying mechanism can also be applied as a standalone feature. The main difference in normal packet mode (non-TCP Segmentation) is that only the checksum fields in the IP/TCP/UDP headers need to be updated.

Before taking advantage of the I350's enhanced checksum off-load capability, a checksum context must be initialized. For the normal transmit checksum off-load feature this is performed by providing the device with a Descriptor with *TSE* = 0b in the *TDESC.DCMD* field and setting either the *TXSM* or *IXSM* bits in the *TDESC.POPTS* field. Setting *TSE* = 0b indicates that the normal checksum context is being set, as opposed to the segmentation context. For additional details on contexts, refer to [Section 7.2.2.4](#).

**Note:** Enabling the checksum off loading capability without first initializing the appropriate checksum context leads to unpredictable results. CRC appending (*TDESC.CMD.IFCS*) must be enabled in TCP/IP checksum mode, since CRC must be inserted by hardware after the checksum has been calculated.

As mentioned in [Section 7.2.2](#), it is not necessary to set a new context for each new packet. In many cases, the same checksum context can be used for a majority of the packet stream. In this case, some performance can be gained by only changing the context on an as needed basis or electing to use the off-load feature only for a particular traffic type, thereby avoiding the need to read all context descriptors except for the initial one.

Each checksum operates independently. Insertion of the IP and TCP checksum for each packet are enabled through the Transmit Data Descriptor *POPTS.TSXM* and *POPTS.IXSM* fields, respectively.

### 7.2.5.1 IP Checksum

Three fields in the Transmit Context Descriptor (*TDESC*) set the context of the IP checksum off loading feature:

- *TUCMD.IPv4*
- *IPLen*
- *MACLen*

*TUCMD.IPv4* = 1b specifies that the packet type for this context is IPv4, and that the IP header checksum should be inserted. *TUCMD.IPv4* = 0b indicates that the packet type is IPv6 (or some other protocol) and that the IP header checksum should not be inserted.

*MACLen* specifies the byte offset from the start of the DMA'd data to the first byte to be included in the checksum, the start of the IP header. The minimal allowed value for this field is 12. Note that the maximum value for this field is 127. This is adequate for typical applications.

**Note:** The *MACLen* + *IPLen* value needs to be less than the total DMA length for a packet. If this is not the case, the results are unpredictable.

*IPLen* specifies the IP header length. Maximum allowed value for this field is 511 Bytes.

*MACLen* + *IPLen* specify where the IP checksum should stop. This is limited to the first 127 + 511 bytes of the packet and must be less than or equal to the total length of a given packet. If this is not the case, the result is unpredictable.

The 16-bit IPv4 Header Checksum is placed at the two bytes starting at *MACLen* + 10.

As mentioned in [Section 7.2.2.2](#), Transmit Contexts, it is not necessary to set a new context for each new packet. In many cases, the same checksum context can be used for a majority of the packet stream. In this case, some performance can be gained by only changing the context on an as needed basis or electing to use the off-load feature only for a particular traffic type, thereby avoiding all context descriptor reads except for the initial one.

### 7.2.5.2 TCP/UDP Checksum

Three fields in the Transmit Context Descriptor (*TDESC*) set the context of the TCP/UDP checksum off loading feature:

- *MACLen*
- *IPLen*
- *TUCMD.L4T*

$TUCMD.L4T = 01b$  specifies that the packet type is TCP, and that the 16-bit TCP header checksum should be inserted at byte offset  $MACLEN + IPLEN + 16$ .  $TUCMD.L4T = 00b$  indicates that the packet is UDP and that the 16-bit checksum should be inserted starting at byte offset  $MACLEN + IPLEN + 6$ .

$IPLEN + MACLEN$  specifies the byte offset from the start of the DMA'd data to the first byte to be included in the checksum, the start of the TCP header. The minimal allowed value for this sum is 32/42 for UDP or TCP respectively.

**Note:** The  $IPLEN + MACLEN + L4LEN$  value needs to be less than the total DMA length for a packet. If this is not the case, the results are unpredictable.

The TCP/UDP checksum always continues to the last byte of the DMA data.

**Note:** For non-TSO, software still needs to calculate a full checksum for the TCP/UDP pseudo-header. This checksum of the pseudo-header should be placed in the packet data buffer at the appropriate offset for the checksum calculation.

### 7.2.5.3 SCTP CRC Offloading

For SCTP packets, a CRC32 checksum offload is provided.

Three fields in the Transmit Context Descriptor ( $TDESC$ ) set the context of the STCP checksum offloading feature:

- $MACLEN$
- $IPLEN$
- $TUCMD.L4T$

$TUCMD.L4T = 10b$  specifies that the packet type is SCTP, and that the 32-bit STCP CRC should be inserted at byte offset  $MACLEN + IPLEN + 8$ .

$IPLEN + MACLEN$  specifies the byte offset from the start of the DMA'd data to the first byte to be included in the checksum, the start of the STCP header. The minimal allowed value for this sum is 26.

The SCTP CRC calculation always continues to the last byte of the DMA data.

The SCTP total L3 payload size ( $TDESCD.PAYLEN - IPLEN - MACLEN$ ) should be a multiple of 4 bytes (SCTP padding not supported).

#### Notes:

1. TSO is not available for SCTP packets.
2. The CRC field of the SCTP header must be set to zero prior to requesting a CRC calculation offload.

### 7.2.5.4 Checksum Supported Per Packet Types

The following table summarizes which checksum is supported per packet type.

**Note:** TSO is not supported for packet types for which IP checksum & TCP checksum can not be calculated.

**Table 7-46 Checksum Per Packet Type**

| Packet Type                                                                                                                                                                                                                                 | Hardware IP Checksum Calculation                                         | Hardware TCP/UDP/SCTP Checksum Calculation                               |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|--------------------------------------------------------------------------|
| IPv4 packets                                                                                                                                                                                                                                | Yes                                                                      | Yes                                                                      |

1. For the tunneled case, the driver might do only the TCP checksum or IPv4 checksum. If TCP checksum is desired, the driver should define the IP header length as the combined length of both IP headers in the packet. If an IPv4 checksum is required, the IP header length should be set to the IPv4 header length.
2. Depends on number of VLAN tags.

## 7.2.6 Multiple Transmit Queues

The number of transmit queues is 8, to match the expected number of CPU cores on server processors and to support virtualization mode.

If there are more CPUs cores than queues, then one queue might be used to service more than one CPU.

For transmission process, each thread might place a queue in the host memory of the CPU it is tied to.

The I350 supports assigning either high or low priority to each transmit queue. High priority is assigned to by setting the `TXDCTL[n].priority` bit to 1. When high priority is assigned to a specific transmit queue, the I350 will always prioritize transmit data fetch DMA accesses, before servicing transmit data fetch of lower priority transmit queues on a specific Physical Function.

**Note:** Throughput of low priority transmit queues can be significantly impacted if high priority queues utilize the DMA resources fully.

## 7.3 Interrupts

### 7.3.1 Interrupt Modes

The I350 supports the following interrupt modes:

- PCI legacy interrupts or MSI - selected when *GPiE.Multiple\_MSIX* is 0b
- MSI-X in non-IOV mode - selected when *GPiE.Multiple\_MSIX* is 1b and the *VFE* bit in PCIe SR-IOV control register is cleared.
- MSI-X in IOV mode - selected when *GPiE.Multiple\_MSIX* is 1b and the *VFE* bit in PCIe SR-IOV control register is set.

#### 7.3.1.1 MSI-X and Vectors

MSI-X defines a separate optional extension to basic MSI functionality. Compared to MSI, MSI-X supports a larger maximum number of vectors per function, the ability for software to control aliasing when fewer vectors are allocated than requested, plus the ability for each vector to use an independent address and data value, specified by a table that resides in Memory Space. However, most of the other characteristics of MSI-X are identical to those of MSI. For more information on MSI-X, refer to the PCI Local Bus Specification, Revision 3.0.

MSI-X maps each of the I350 interrupt causes into an interrupt vector that is conveyed by the I350 as a posted-write PCIe transaction. Mapping of an interrupt cause into an MSI-X vector is determined by system software (a device driver) through a translation table stored in the MSI-X Allocation registers. Each entry of the allocation registers defines the vector for a single interrupt cause.

##### 7.3.1.1.1 Usage of Spare MSI-X Vectors by Physical Function

In an IOV mode, it is possible that not all the Virtual functions are activated. In this case, part of the MSI-X vectors are not used. The PF might then claim part of these for its own use in addition to the single MSI-X vector allocated to it. The PF function requests MSI-X vectors according to the following formula:

$$\text{PF vector requested} = \text{MIN}(\text{PF vectors in EEPROM}, 25 - 3 * \text{NumVFs}).$$

### 7.3.2 Mapping of Interrupt Causes

There are 18 extended interrupt causes that exist in the I350:

1. 16 traffic causes — 8 Tx, 8 Rx.
2. TCP timer
3. Other causes — Summarizes legacy interrupts into one extended cause.

The way the I350 exposes causes to the software is determined by the interrupt mode as described below.

Mapping of interrupts causes is different in each of the interrupt modes and is described in the following sections of this chapter.

**Note:** If only one MSI-X vector is allocated by the operating system, then the driver might use the non MSI-X mapping method even in MSI-X mode.

### 7.3.2.1 Legacy and MSI Interrupt Modes

In legacy and MSI modes, an interrupt cause is reflected by setting a bit in the *EICR* register. This section describes the mapping of interrupt causes, like a specific Rx queue event or a Link Status Change event, to bits in the *EICR* register.

Mapping of queue-related causes is accomplished through the *IVAR* register. Each possible queue interrupt cause (each RX or TX queue) is allocated an entry in the *IVAR*, and each entry in the *IVAR* identifies one bit in the *EICR* register among the bits allocated to queue interrupt causes. It is possible to map multiple interrupt causes into the same *EICR* bit.

In this mode, different queue related interrupt causes can be mapped to the first 8 bits of the *EICR* register.

Interrupt causes related to non-queue causes are mapped into the *ICR* legacy register; each cause is allocated a separate bit. The sum of all causes is reflected in the *Other Cause* bit in *EICR*. [Figure 7-12](#) below describes the allocation process.

The following configuration and parameters are involved:

- The *IVAR*[3:0] entries map 8 Tx queues and 8 Rx queues into the *EICR*[7:0] bits.
- The *IVAR\_MISC* that maps non-queue causes is not used.
- The *EICR*[30] bit is allocated to the TCP timer interrupt cause.
- The *EICR*[31] bit is allocated to the other interrupt causes summarized in the *ICR* register.
- A single interrupt vector is provided.

**Figure 7-12 Cause Mapping in Legacy Mode**

The Table below maps the different interrupt causes into the *IVAR* registers.

**Table 7-47 Cause Allocation in the IVAR Registers - MSI and Legacy Mode**

| Interrupt | Entry                  | Description                                                                                                            |
|-----------|------------------------|------------------------------------------------------------------------------------------------------------------------|
| Rx_i      | $i*2$ ( $i= 0...7$ )   | Receive queues i - Associates an interrupt occurring in the RX queue I with a corresponding bit in the EICR register.  |
| Tx_i      | $i*2+1$ ( $i= 0...7$ ) | Transmit queues i - Associates an interrupt occurring in the TX queue I with a corresponding bit in the EICR register. |

### 7.3.2.2 MSI-X Mode - Non-IOV Mode

In MSI-X mode, in a non Single Root - IOV setup (SR-IOV capability is not exposed in the PCIe config space), the I350 can request up to 25 Vectors.

In MSI-X mode, an interrupt cause is mapped into an MSI-X vector. This section describes the mapping of interrupt causes, like a specific RX queue event or a Link Status Change event, to MSI-X vectors.

Mapping is accomplished through the *IVAR* register. Each possible cause for an interrupt is allocated an entry in the *IVAR*, and each entry in the *IVAR* identifies one MSI-X vector. It is possible to map multiple interrupt causes into the same MSI-X vector.

The *EICR* also reflects interrupt vectors. The *EICR* bits allocated for queue causes reflect the MSI-X vector (bit 2 is set when MSI-X vector 2 is used). Interrupt causes related to non-queue causes are mapped into the *ICR* (as in the legacy case). The MSI-X vector for all such causes is reflected in the *EICR*.

The following configuration and parameters are involved:

- The *IVAR[3:0]* registers map 8 Tx queues and 8 Rx queues events to up to 23 interrupt vectors
- The *IVAR\_MISC* register maps a TCP timer and other events to 2 MSI-X vectors

Figure 7-13 describes the allocation process.

**Figure 7-13 Cause Mapping in MSI-X Mode**

Table 7-48 below defines which interrupt cause is represented by each entry in the MSI-X Allocation registers. In non IOV mode, the The software has access to 18 mapping entries to map each cause to one of the 25 MSI-x vectors.

**Table 7-48 Cause Allocation in the IVAR Registers - Non-IOV Mode**

| Interrupt   | Entry                  | Description                                                                                                                           |
|-------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Rx_i        | $i*2$ ( $i= 0...7$ )   | Receive queues i - Associates an interrupt occurring in the RX queue I with a corresponding entry in the MSI-X Allocation registers.  |
| Tx_i        | $i*2+1$ ( $i= 0...7$ ) | Transmit queues i- Associates an interrupt occurring in the TX queues I with a corresponding entry in the MSI-X Allocation registers. |
| TCP timer   | 16                     | TCP Timer - Associates an interrupt issued by the TCP timer with a corresponding entry in the MSI-X Allocation registers              |
| Other cause | 17                     | Other causes - Associates an interrupt issued by the "other causes" with a corresponding entry in the MSI-X Allocation registers      |

### 7.3.2.3 MSI-X Interrupts in IOV Mode

Each of the VF functions in PCI-SIG IOV mode is allocated 3 MSI-X vectors. The PF is allocated all the unused vectors and a minimum of 10 vectors.

Interrupt allocation for the physical function (PF) is done as in the MSI-X non-IOV case. However, the PF should not assign interrupt vectors to queues not assigned to it. The *IVAR\_MISC* register allocates non-queue interrupts as in the non-IOV case with a single change - the entry assigned to "other" causes also handles interrupt on the mailbox.

Each of the VFs in IOV mode is allocated separate *IVAR* registers (called *VTIVAR*), translating its queue-related interrupt causes into MSI-X vectors for this virtual function. The *IVAR* register has one entry per Tx or Rx queue. A *VTIVAR\_MISC* register is provided to map the mailbox interrupt into an MSI-X vector.

The PF can allocate interrupt causes not used by the VFs to one of its own vectors.

The *EICR* of each VF or of the PF reflects the status of the MSI-X vectors allocated to this function.

**Figure 7-14 Cause Mapping of a VF in MSI-X Mode (IOV)**

Table 7-49 below, defines for a given VM (not PF) which interrupt cause is represented by each entry in the MSI-X Allocation registers.

In the IOV mode Software has access to 3 mapping entries to map each cause to one of the 3 MSI-x vectors.

The 3 VM vectors (per each VM) can be allocated to one or more causes (1 queue RX traffic interrupt, 1 queue TX traffic interrupt and Mail Box interrupt).

Please refer to [Section 7.8.2.9.1](#) for details of the Mail Box mechanism.

**Table 7-49 Cause Allocation for a VF in the VT/VAR Registers - IOV Mode**

| Interrupt | Entry | Description                                                                                                     |
|-----------|-------|-----------------------------------------------------------------------------------------------------------------|
| Rx Queue  | 0     | Associates an interrupt occurring in the Rx queue with a corresponding entry in the MSI-X Allocation registers. |
| Tx Queue  | 1     | Associates an interrupt occurring in the Tx queue with a corresponding entry in the MSI-X Allocation registers. |

### 7.3.3 Legacy Interrupt Registers

The interrupt logic consists of the registers listed in the tables below, plus the registers associated with MSI/MSI-X signaling. The first table describes the use of the registers in legacy mode and the second one the use of the registers when using the extended interrupts functionality

**Table 7-50 Interrupt Registers - Legacy Mode**

| Register                        | Acronym | Function                                                                                                           |
|---------------------------------|---------|--------------------------------------------------------------------------------------------------------------------|
| Interrupt Cause                 | ICR     | Records interrupt conditions.                                                                                      |
| Interrupt Cause Set             | ICS     | Allows software to set bits in the ICR.                                                                            |
| Interrupt Mask Set/Read         | IMS     | Sets or reads bits in the interrupt mask.                                                                          |
| Interrupt Mask Clear            | IMC     | Clears bits in the interrupt mask.                                                                                 |
| Interrupt Acknowledge auto-mask | IAM     | Under some conditions, the content of this register is copied to the mask register following read or write of ICR. |

**Table 7-51 Interrupt Registers - Extended Mode**

| Register                                 | Acronym | Function                                                                                                                                                                                                                                                                                      |
|------------------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Extended Interrupt Cause                 | EICR    | Records interrupt causes from receive and transmit queues. An interrupt is signaled when unmasked bits in this register are set.                                                                                                                                                              |
| Extended Interrupt Cause Set             | EICS    | Allows software to set bits in the Interrupt Cause register.                                                                                                                                                                                                                                  |
| Extended Interrupt Mask Set/Read         | EIMS    | Sets or read bits in the interrupt mask.                                                                                                                                                                                                                                                      |
| Extended Interrupt Mask Clear            | EIMC    | Clears bits in the interrupt mask.                                                                                                                                                                                                                                                            |
| Extended Interrupt Auto Clear            | EIAC    | Allows bits in the EICR to be cleared automatically following an MSI-X interrupt without a read or write of the EICR.                                                                                                                                                                         |
| Extended Interrupt Acknowledge auto-mask | EIAM    | This register is used to decide which masks are cleared in the extended mask register following read or write of EICR or which masks are set following a write to EICS. In MSI-X mode, this register also controls which bits in EIMC are cleared automatically following an MSI-X interrupt. |
| Interrupt Cause                          | ICR     | Records interrupt conditions for special conditions - a single interrupt from all the conditions of ICR is reflected in the "other" field of the EICR.                                                                                                                                        |
| Interrupt Cause Set                      | ICS     | Allows software to set bits in the ICR.                                                                                                                                                                                                                                                       |
| Interrupt Mask Set/Read                  | IMS     | Sets or reads bits in the other interrupt mask.                                                                                                                                                                                                                                               |
| Interrupt Mask Clear                     | IMC     | Clears bits in the Other interrupt mask.                                                                                                                                                                                                                                                      |
| Interrupt Acknowledge auto-mask          | IAM     | Under some conditions, the content of this register is copied to the mask register following read or write of ICR.                                                                                                                                                                            |
| General Purpose Interrupt Enable         | GPIE    | Controls different behaviors of the interrupt mechanism.                                                                                                                                                                                                                                      |

### 7.3.3.1 Interrupt Cause Register (ICR)

#### 7.3.3.1.1 Legacy Mode

In Legacy mode, *ICR* is used as the sole interrupt cause register. Upon reception of an interrupt, the interrupt handling routine can read this register in order to find out what are the causes of this interrupt.

#### 7.3.3.1.2 Advanced Mode

In advanced mode, this register captures the interrupt causes not directly captured by the *EICR*. These are infrequent management interrupts and error conditions.

Note that when *EICR* is used in advanced mode, the RX /TX related bits in *ICR* should be masked.

*ICR* bits are cleared on register read. If *GPIE.NSICR* = 0b, then the clear on read occurs only if no bit is set in the *IMS* register or at least one bit is set in the *IMS* register and there is a true interrupt as reflected in the *ICR.INTA* bit.

### 7.3.3.2 Interrupt Cause Set Register (ICS)

This register allows software to set bits in the *ICR* register. Writing a 1b in an *ICS* bit causes the corresponding bit in the *ICR* register to be set. Used usually to re-arm interrupts the software device driver didn't have time to handle in the current interrupt routine.

### 7.3.3.3 Interrupt Mask Set/Read Register (IMS)

An interrupt is enabled if its corresponding mask bit in this register is set to 1b, and disabled if its corresponding mask bit is set to 0b. A PCIe interrupt is generated whenever one of the bits in this register is set, and the corresponding interrupt condition occurs. The occurrence of an interrupt condition is reflected by having a bit set in the *Interrupt Cause Register (ICR)*.

Reading this register returns which bits have an interrupt mask set.

A particular interrupt might be enabled by writing a 1b to the corresponding mask bit in this register. Any bits written with a 0b are unchanged. Thus, if software desires to disable a particular interrupt condition that had been previously enabled, it must write to the Interrupt Mask Clear (*IMC*) Register, rather than writing a 0b to a bit in this register.

### 7.3.3.4 Interrupt Mask Clear Register (IMC)

Software blocks interrupts by clearing the corresponding mask bit. This is accomplished by writing a 1b to the corresponding bit in this register. Bits written with 0b are unchanged (their mask status does not change).

### 7.3.3.5 Interrupt Acknowledge Auto-mask register (IAM)

An *ICR* read or write has the side effect of writing the contents of this register to the *IMC* register to auto-mask additional interrupts from the *ICR* bits in the locations where the *IAM* bits are set. If *GPIE.NSICR* = 0b, then the copy of this register to the *IMC* register occurs only if at least one bit is set in the *IMS* register and there is a true interrupt as reflected in the *ICR.INTA* bit.

### 7.3.3.6 Extended Interrupt Cause Registers (EICR)

#### 7.3.3.6.1 MSI/INT-A Mode (*GPIE.Multiple\_MSIX* = 0)

This register records the interrupts causes, to provide Software with information on the interrupt source.

The interrupt causes include:

1. The Receive and Transmit queues — Each queue (either Tx or Rx) can be mapped to one of the 8 interrupt causes bits (RxTxQ) available in this register according to the mapping in the *IVAR* registers
2. Indication for the TCP timer interrupt.
3. Legacy and other indications — When any interrupt in the Interrupt Cause register is active.

Writing a 1b clears the corresponding bit in this register. Reading this register auto-clears all bits.

#### 7.3.3.6.2 MSI-X Mode (*GPIE.Multiple\_MSIX* = 1)

This register records the interrupt vectors currently emitted. In this mode only the first 25 bits are valid.

For all the subsequent registers, in MSI-X mode, each bit controls the behavior of one vector.

Bits in this register can be configured to auto-clear when the MSI-X interrupt message is sent, in order to minimize driver overhead when using MSI-X interrupt signaling.

Writing a 1b clears the corresponding bit in this register. Reading this register does not clear any bits.

### 7.3.3.7 Extended Interrupt Cause Set Register (EICS)

This register enables the software device driver to set *EICR* bits. Writing a 1b in a *EICS* bit causes the corresponding bit in the *EICR* register to be set. Used usually to re-arm interrupts that the software didn't have time to handle in the current interrupt routine.

### 7.3.3.8 Extended Interrupt Mask Set and Read Register (EIMS) & Extended Interrupt Mask Clear Register (EIMC)

Interrupts appear on PCIe only if the interrupt cause bit is a one and the corresponding interrupt mask bit is a one. Software blocks assertion of an interrupt by clearing the corresponding bit in the mask register. The cause bit stores the interrupt event regardless of the state of the mask bit. Different Clear (*EIMC*) and set (*EIMS*) registers make this register more “thread safe” by avoiding a read-modify-write

operation on the mask register. The mask bit is set for each bit written as a one in the set register (*EIMS*) and cleared for each bit written as a one in the clear register (*EIMC*). Reading the set register (*EIMS*) returns the current mask register value.

### 7.3.3.9 Extended Interrupt Auto Clear Enable Register (EIAC)

Each bit in this register enables clearing of the corresponding bit in *EICR* following interrupt generation. When a bit is set, the corresponding bit in the *EICR* register is automatically cleared following an interrupt. This feature should only be used in MSI-X mode.

When used in conjunction with MSI-X interrupt vector, this feature allows interrupt cause recognition, and selective interrupt cause, without requiring software to read or write the *EICR* register; therefore, the penalty related to a PCIe read or write transaction is avoided.

See [section 7.3.4](#) for additional information on the interrupt cause reset process.

### 7.3.3.10 Extended Interrupt Auto Mask Enable Register (EIAM)

Each bit set in this register enables clearing of the corresponding bit in the extended mask register following read or write-to-clear to *EICR*. It also enables setting of the corresponding bit in the extended mask register following a write-to-set to *EICS*.

This mode is provided in case MSI-X is not used, and therefore auto-clear through *EIAC* register is not available.

In MSI-X mode, the driver software might set the bits of this register to select mask bits that must be reset during interrupt processing. In this mode, each bit in this register enables clearing of the corresponding bit in *EIMC* following interrupt generation.

### 7.3.3.11 GPIE Register

There are a few bits in the *GPIE* register that define the behavior of the interrupt mechanism. The setting of these bits is different in each mode of operation. The following table describes the recommended setting of these bits in the different modes:

**Table 7-52 Settings for Different Interrupt Modes**

| Field          | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                           | INT-x/<br>MSI +<br>Legacy | INT-x/<br>MSI +<br>Extend | MSI-X<br>Multi<br>vector | MSI-X<br>Single<br>vector |
|----------------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|---------------------------|--------------------------|---------------------------|
| NSICR          | 0      | 0b            | <b>Non Selective Interrupt clear on read:</b> When set, every read of the <i>ICR</i> register clears the <i>ICR</i> register. When this bit is cleared, an <i>ICR</i> register read causes the <i>ICR</i> register to be cleared only if an actual interrupt was asserted or <i>IMS</i> = 0x0.                        | 0b <sup>1</sup>           | 1b                        | 1b                       | 1b                        |
| Multiple_ MSIX | 4      | 0b            | <b>Multiple_ MSIX - multiple vectors:</b><br>0b = non-MSIX or MSI-X with 1 vector <i>IVAR</i> maps Rx/Tx causes to 8 <i>EICR</i> bits, but MSIX[0] is asserted for all.<br>1b = MSIX mode, <i>IVAR</i> maps Rx/Tx causes to 25 <i>EICR</i> bits.<br>When set, the <i>EICR</i> register is not clear on read.          | 0b                        | 0b                        | 1b                       | 0b                        |
| EIAME          | 30     | 0b            | <b>EIAME:</b> When set, upon firing of an MSI-X message, mask bits set in <i>EIAM</i> associated with this message are cleared. Otherwise, <i>EIAM</i> is used only upon read or write of <i>EICR</i> / <i>EICS</i> registers.                                                                                        | 0b                        | 0b                        | 1b                       | 1b                        |
| PBA_ support   | 31     | 0b            | <b>PBA support:</b> When set, setting one of the extended interrupts masks via <i>EIMS</i> causes the PBA bit of the associated MSI-X vector to be cleared. Otherwise, the I350 behaves in a way that supports legacy INT-x interrupts.<br>Should be cleared when working in INT-x or MSI mode and set in MSI-X mode. | 0b                        | 0b                        | 1b                       | 1b                        |

1. In systems where interrupt sharing is not expected, the *NSICR* bit can be set by legacy drivers also.

As this register affects the way the hardware interprets write operations to other interrupt control registers, it should be set to the correct mode before accessing other interrupt control registers.

## 7.3.4 Clearing Interrupt Causes

The I350 has three methods available to clear *EICR* bits: Autoclear, clear-on-write, and clear-on-read. *ICR* bits might only be cleared with clear-on-write or clear-on-read.

### 7.3.4.1 Auto-Clear

In systems that support MSI-X, the interrupt vector allows the interrupt service routine to know the interrupt cause without reading the *EICR*. With interrupt moderation active, software load from spurious interrupts is minimized. In this case, the software overhead of a I/O read or write can be avoided by setting appropriate *EICR* bits to autoclear mode by setting the corresponding bits in the Extended Interrupt Auto-clear Enable Register (*EIAC*).

When auto-clear is enabled for an interrupt cause, the *EICR* bit is set when a cause event mapped to this vector occurs. When the *EITR* Counter reaches zero, the MSI-X message is sent on PCIe. Then the *EICR* bit is cleared and enabled to be set by a new cause event. The vector in the MSI-X message signals software the cause of the interrupt to be serviced.

It is possible that in the time after the *EICR* bit is cleared and the interrupt service routine services the cause, for example checking the transmit and receive queues, that another cause event occurs that is then serviced by this ISR call, yet the *EICR* bit remains set. This results in a “spurious interrupt”. Software can detect this case, for example if there are no entries that require service in the transmit and receive queues, and exit knowing that the interrupt has been automatically cleared. The use of interrupt moderations through the *EITR* register limits the extra software overhead that can be caused by these spurious interrupts.

### 7.3.4.2 Write to Clear

In the case where the driver wishes to configure itself in MSI-X mode to not use the “auto-clear” feature, it might clear the *EICR* bits by writing to the *EICR* register. Any bits written with a 1b is cleared. Any bits written with a 0b remain unchanged.

### 7.3.4.3 Read to Clear

The *EICR* and *ICR* registers are cleared on a read.

**Note:** The driver should never do a read-to-clear of the *EICR* when in MSI-X mode, since this might clear interrupt cause events which are processed by a different interrupt handler (assuming multiple vectors).

## 7.3.5 Interrupt Moderation

An interrupt is generated upon receiving of incoming packets, as throttled by the *EITR* registers (see [Section 8.8.14](#)). There is an *EITR* register per MSI-X vector.

In MSI-X mode, each active bit in *EICR* can trigger the interrupt vector it is allocated to. Following the allocation, the *EITR* corresponding to the MSI-X vector is tied to one or more bits in *EICR*.

When multi vector MSI-X is not activated, the interrupt moderation is controlled by register *EITR*[0].

Software can use *EITR* to limit the rate of delivery of interrupts to the host CPU. This register provides a guaranteed inter-interrupt delay between interrupts asserted by the network controller, regardless of network traffic conditions.

The following formula converts the inter-interrupt interval value to the common 'interrupts/sec.' performance metric:

$$\text{interrupts/sec} = (1 * 10^{-6} \text{sec} \times \text{interval})^{-1}$$

**Note:** In the I350 the interval granularity is 1  $\mu\text{sec}$  so some of the LSB bits of the interval are used for the low latency interrupt moderation.

For example, if the interval is programmed to 125d, the network controller guarantees the CPU is not interrupted by the network controller for at least 125  $\mu\text{s}$  from the last interrupt. In this case, the maximum observable interrupt rate from the adapter should not exceed 8000 interrupts/sec.

Inversely, inter-interrupt interval value can be calculated as:

$$\text{inter-interrupt interval} = (1 * 10^{-6} \text{sec} \times \text{interrupt/sec})^{-1}$$

The optimal performance setting for this register is system and configuration specific.

The Extended Interrupt Throttle Register should default to zero upon initialization and reset. It loads in the value programmed by the software after software initializes the device.

When software wants to force an immediate interrupt, for example after setting a bit in the *EICR* with the Extended Interrupt Cause Set register, a value of 0 can be written to the Counter to generate an interrupt immediately. This write should include re-writing the *Interval* field with the desired constant, as it is used to reload the Counter immediately for the next throttling interval.

The I350 implements interrupt moderation to reduce the number of interrupts software processes. The moderation scheme is based on the *EITR* (Interrupt Throttle Register). Whenever an interrupt event happens, the corresponding bit in the *EICR* is activated. However, an interrupt message is not sent out on the PCIe interface until the *EITR* counter assigned to that *EICR* bit has counted down to zero. As soon as the interrupt is issued, the *EITR* counter is reloaded with its initial value and the process repeats again. The interrupt flow should follow the diagram below:

**Figure 7-15** Interrupt Throttle Flow Diagram

EITR is designed to guarantee the total number of interrupts per second so for cases where the I350 is connected to a network with low traffic load, if the *EITR* counter counted down to zero and no interrupt event has happened, then the *EITR* counter is not re-armed but stays at zero. Thus, the next interrupt event triggers an interrupt immediately. That scenario is illustrated as “Case B” below.

**Figure 7-16 Case A: Heavy Load, Interrupts Moderated**

**Figure 7-17 Light load, Interrupts Immediately on Packet Receive**

## 7.3.6 Rate Controlled Low Latency Interrupts (LLI)

There are some types of network traffic for which latency is a critical issue. For these types of traffic, interrupt moderation hurts performance by increasing latency between the time a packet is received by hardware and the time it is handled to the host operating system. This traffic can be identified by the 2-tuple value, in conjunction with Control Bits and specific size. In addition packets with specific Ethernet types, TCP flag or specific VLAN priority might generate an immediate interrupt.

Low latency interrupts shares the filters used by the queueing mechanism described in [Section 7.1.1](#). Each of these filters, in addition to the queueing action might also indicate matching packets might generate immediate interrupt.

If a received packet matches one of these filters, hardware should interrupt immediately, overriding the interrupt moderation by the *EITR* counter.

Each time a Low Latency Interrupt is fired, the *EITR* interval is loaded and down-counting starts again.

The logic of the low latency interrupt mechanism is as follows:

- There are 8 2-tuple filters. The content of each filter is described in [Section 7.1.2.5](#). The immediate interrupt action of each filter can be enabled or disabled. If one of the filters detects an adequate packet, an immediate interrupt is issued.

- There are 8 flex filters. The content of each filter is described in [Section 7.1.2.6](#). The immediate interrupt action of each filter can be enabled or disabled. If one of the filters detects an adequate packet, an immediate interrupt is issued.
- When VLAN priority filtering is enabled, VLAN packets must trigger an immediate interrupt when the VLAN Priority is equal to or above the VLAN priority threshold. This is regardless of the status of the 2-tuple or Flex filters.
- The SYN packets filter defined in [Section 7.1.2.7](#) and the ethernet type filters defined in [Section 7.1.2.4](#) might also be used to indicate low latency interrupt conditions.

**Note:** Immediate interrupts are available only when using advanced receive descriptors and not for legacy descriptors.

Packets that are dropped or have errors do not cause a Low Latency Interrupt.

### 7.3.6.1 Rate Control Mechanism

In a network with lots of latency sensitive traffics the Low Latency Interrupt can eliminate the Interrupt throttling capability by flooding the Host with too many interrupts (more than the Host can handle).

In order to mitigate the above, the I350 supports a credit base mechanism to control the rate of the Low Latency Interrupts.

Rules:

- The default value of each counter is 0b (no moderation). This also preserves backward compatibility.
- The counter increments at a configurable rate, and saturates at the maximum value (31d).
  - The configurable rate granularity is 4  $\mu$ s (250K interrupt/sec. down to 250K/32 ~ 8K interrupts per sec.).
- A LLI might be issued as long as the counter value is strictly positive (> zero).
  - The credit counter allows bursts of low latency interrupts but the interrupt average are not more than the configured rate.
- Each time a Low Latency Interrupt is fired the credit counter decrements by one.
- Once the counter reaches zero, a low latency interrupt cannot be fired
  - Must wait for the next ITR expired or for the next incrementing of this counter (if the EITR expired happened first the counter does not decrement).

The *EITR* and *GPIE* registers manage rate control of *LLI*:

- The *LL Interval* field in the *GPIE* register controls the rate of credits
- The 5-bit *LL Counter* field in the *EITR* register contains the credits

## 7.3.7 TCP Timer Interrupt

### 7.3.7.1 Introduction

The TCP Timer interrupt provides an accurate and efficient way for a periodic timer to be implemented using hardware. The driver would program a timeout value (usual value of 10 ms), and each time the timer expires, hardware sets a specific bit in the *EICR*. When an interrupt occurs (due to normal interrupt moderation schemes), software reads the *EICR* and discovers that it needs to process timer events during that DPC.

The timeout should be programmable by the driver, and the driver should be able to disable the timer interrupt if it is not needed.

### 7.3.7.2 Description

A stand-alone down-counter is implemented. An interrupt is issued each time the value of the counter is zero.

The software is responsible for setting initial value for the timer in the *TCPTIMER.Duration* field. Kick-starting is done by writing a 1b to the *TCPTIMER.KickStart* bit.

Following the kick-start, an internal counter is set to the value defined by the *TCPTIMER.Duration* field. Then during the count operation, the counter is decreased by one each millisecond. When the counter reaches zero, an interrupt is issued (see EICR register [Section 8.8.3](#)). The counter re-starts counting from its initial value if the *TCPTIMER.Loop* field is set.

## 7.3.8 Setting of Interrupt Registers

In each mode, the registers controlling the interrupts should be set in a different way to assure the right behavior.

**Table 7-53 Registers Settings for Different Interrupt Modes**

| Field       | Description                            | INT-x/MSI + Legacy                         | INT-x/ MSI + Extend | MSI-X Multi vector        | MSI-X Single vector |
|-------------|----------------------------------------|--------------------------------------------|---------------------|---------------------------|---------------------|
| IMS         | Legacy Masks                           | Set <sup>1</sup>                           | Set <sup>2</sup>    | Set <sup>2</sup>          | Set <sup>2</sup>    |
| IAM         | Legacy Auto Mask Register              | May be Set                                 | 0x0                 | 0x0                       | 0x0                 |
| EIMS        | Extended Masks                         | Set Other Cause only.                      | Set <sup>1</sup>    | Set <sup>1</sup>          | Set <sup>1</sup>    |
| EIAC        | Extended Auto Clear register           | 0x0                                        | 0x0                 | At least one <sup>3</sup> | 0x0                 |
| EIAM        | Extended Auto Mask Register            | 0x0                                        | Set <sup>1</sup>    |                           | Set <sup>1</sup>    |
| EITR[0]     | Interrupt Moderation register          | May be Enabled                             | May be Enabled      | Enable <sup>4</sup>       | Enable              |
| EITR[1...n] | Extended Interrupt Moderation register | Disable                                    | Disable             | Enable <sup>4</sup>       | Disable             |
| GPIE        | Interrupts configuration               | See <a href="#">Table 7-52</a> for details |                     |                           |                     |

1. According to the requested causes

2. Only non traffic causes.

3. EIAC or EIAM or both should be set for each cause.

4. EITR must be enabled if Auto Mask is disabled. If Auto Mask is enabled, moderation may be disabled for the specific vector.

## 7.4 802.1q VLAN Support

The I350 provides several specific mechanisms to support 802.1q VLANs:

- Optional adding (for transmits) and stripping (for receives) of IEEE 802.1q VLAN tags.
- Optional ability to filter packets belonging to certain 802.1q VLANs.
- Double VLAN Support.

## 7.4.1 802.1q VLAN Packet Format

The following diagram compares an untagged 802.3 Ethernet packet with an 802.1q VLAN tagged packet:

**Table 7-54 Comparing Packets**

| 802.3 Packet | #Octets |  | 802.1q VLAN Packet | #Octets |
|--------------|---------|--|--------------------|---------|
| DA           | 6       |  | DA                 | 6       |
| SA           | 6       |  | SA                 | 6       |
| Type/Length  | 2       |  | 802.1q Tag         | 4       |
| Data         | 46-1500 |  | Type/Length        | 2       |
| CRC          | 4       |  | Data               | 46-1500 |
|              |         |  | CRC*               | 4       |

**Note:** The CRC for the 802.1q tagged frame is re-computed, so that it covers the entire tagged frame including the 802.1q tag header. Also, max frame size for an 802.1q VLAN packet is 1522 octets as opposed to 1518 octets for a normal 802.3z Ethernet packet.

## 7.4.2 802.1q Tagged Frames

For 802.1q, the *Tag Header* field consists of four octets comprised of the Tag Protocol Identifier (TPID) and Tag Control Information (TCI); each taking 2 octets. The first 16 bits of the tag header makes up the TPID. It contains the “protocol type” which identifies the packet as a valid 802.1q tagged packet.

The two octets making up the TCI contain three fields:

- User Priority (UP)
- Canonical Form Indicator (CFI). Should be 0b for transmits. For receives, the device has the capability to filter out packets that have this bit set. See the *CFIEN* and *CFI* bits in the *RCTL* described in [Section 8.10.1](#).
- VLAN Identifier (VID)

The bit ordering is shown below:

**Table 7-55 TCI Bit Ordering**

| Octet 1 |  |  |     |     |  |  |  | Octet 2 |  |  |  |  |  |  |  |
|---------|--|--|-----|-----|--|--|--|---------|--|--|--|--|--|--|--|
| UP      |  |  | CFI | VID |  |  |  |         |  |  |  |  |  |  |  |
|         |  |  |     |     |  |  |  |         |  |  |  |  |  |  |  |

## 7.4.3 Transmitting and Receiving 802.1q Packets

### 7.4.3.1 Adding 802.1q Tags on Transmits

Software might command the I350 to insert an 802.1q VLAN tag on a per packet or per flow basis. If the *VLE* bit in the transmit descriptor is set to 1b, then the I350 inserts a VLAN tag into the packet that it transmits over the wire. The *Tag Protocol Identifier (TPID)* field of the 802.1q tag comes from the VET register. 802.1Q tag insertion is done in different ways for legacy and advanced Tx descriptors:

- Legacy Transmit Descriptors: The Tag Control Information (TCI) of the 802.1q tag comes from the VLAN field (see [Figure 7-9](#)) of the descriptor. Refer to [Table 7-27](#), for more information regarding hardware insertion of tags for transmits.
- Advanced Transmit Descriptor: The Tag Control Information (TCI) of the 802.1q tag comes from the VLAN Tag field (see [Table 7.2.2.2.1](#)) of the advanced context descriptor. The *IDX* field of the advanced Tx descriptor should be set to the adequate context.

### 7.4.3.2 Stripping 802.1q Tags on Receives

Software might instruct the I350 to strip 802.1q VLAN tags from received packets. If VLAN stripping is enabled and the incoming packet is an 802.1q VLAN packet (its *Ethernet Type* field matched the VET), then the I350 strips the 4 byte VLAN tag from the packet, and stores the TCI in the VLAN Tag field (see [Figure 7-5](#) and See "Packet Checksum" of the receive descriptor).

The I350 also sets the *VP* bit in the receive descriptor to indicate that the packet had a VLAN tag that was stripped. If the *CTRL.VME* bit is not set, the 802.1Q packets can still be received if they pass the receive filter, but the VLAN tag is not stripped and the *VP* bit is not set. Refer [Figure 7-18](#) for more information regarding receive packet filtering.

VLAN stripping can be enabled using two different modes:

1. By setting the *DVMOLR.STRVLAN* for the relevant queue.

By setting the *CTRL.VME* bit.

## 7.4.4 802.1q VLAN Packet Filtering

VLAN filtering is enabled by setting the *RCTL.VFE* bit to 1b. If enabled, hardware compares the type field of the incoming packet to a 16-bit field in the VLAN Ether Type (VET) register. If the VLAN type field in the incoming packet matches the VET register, the packet is then compared against the VLAN Filter Table Array (VFTA[127:0]) for acceptance.

The I350 provides exact VLAN filtering for VLAN tags for host traffic and VLAN tags for manageability traffic.

### Host VLAN filtering:

The *Virtual LAN ID* field indexes a 4096 bit vector. If the indexed bit in the vector is one; there is a Virtual LAN match. Software might set the entire bit vector to ones if the node does not implement 802.1q filtering. The register description of the VLAN Filter Table Array is described in detail in [Section 8.10.18](#).

In summary, the 4096-bit vector is comprised of 128, 32-bit registers. The *VLAN Identifier (VID)* field consists of 12 bits. The upper 7 bits of this field are decoded to determine the 32-bit register in the VLAN Filter Table Array to address and the lower 5 bits determine which of the 32 bits in the register to evaluate for matching.

#### Manageability VLAN filtering:

The BMC configures the I350 with eight different manageability VLANs via the Management VLAN TAG Value [7:0] - MAVTV[7:0] registers and enables each filter in the MDEF register.

Two other bits in the Receive Control register (see [Section 8.10.1](#)), CFIEN and CFI, are also used in conjunction with 802.1q VLAN filtering operations. CFIEN enables the comparison of the value of the CFI bit in the 802.1q packet to the Receive Control register CFI bit as acceptance criteria for the packet.

**Note:** The VFE bit does not affect whether the VLAN tag is stripped. It only affects whether the VLAN packet passes the receive filter.

The following table lists reception actions per control bit settings.

**Figure 7-18 Packet Reception Decision Table**

| Is packet 802.1q? | CTRL. VME      | RCTL. VFE      | Action                                                                                                                                                                                                                  |
|-------------------|----------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No                | X <sup>1</sup> | X <sup>1</sup> | Normal packet reception                                                                                                                                                                                                 |
| Yes               | 0b             | 0b             | Receive a VLAN packet if it passes the standard MAC address filters (only). Leave the packet as received in the data buffer. VP bit in receive descriptor is cleared.                                                   |
| Yes               | 0b             | 1b             | Receive a VLAN packet if it passes the standard filters and the VLAN filter table. Leave the packet as received in the data buffer (the VLAN tag would not be stripped). VP bit in receive descriptor is cleared.       |
| Yes               | 1b             | 0b             | Receive a VLAN packet if it passes the standard filters (only). Strip off the VLAN information (four bytes) from the incoming packet and store in the descriptor. Sets VP bit in receive descriptor.                    |
| Yes               | 1b             | 1b             | Receive a VLAN packet if it passes the standard filters and the VLAN filter table. Strip off the VLAN information (four bytes) from the incoming packet and store in the descriptor. Sets VP bit in receive descriptor. |

1. X - Don't care

**Note:** A packet is defined as a VLAN/802.1q packet if its type field matches the VET.

## 7.4.5 Double VLAN Support

The I350 supports a mode where most of the received and sent packet have at least one VLAN tag in addition to the regular tagging which might optionally be added. This mode is used for systems where the switches add an additional tag containing switching information.

**Note:** The only packets that may not have the additional VLAN are local packets that will not have any VLAN tag.

This mode is activated by setting CTRL\_EXT.EXT\_VLAN bit. The default value of this bit is set according to the EXT\_VLAN (bit 1) in the *Initialization Control 3* EEPROM word for ports 0 to 3. See [Section 6.2.26](#) for more information.

The type of the VLAN tag used for the additional VLAN is defined in the VET.VET\_EXT field.

## 7.4.5.1 Transmit Behavior With External VLAN

It is expected that the driver include the external VLAN header as part of the transmit data structure. The software may post the internal VLAN header as part of the transmit data structure or embedded in the transmit descriptor (see [Section 7.2.2](#) for details). The I350 does not relate to the external VLAN header other than the capability of “skipping” it for parsing of inner fields.

### Notes:

- If the `CTRL_EXT.EXT_VLAN` bit is set the VLAN header in a packet that carries a single VLAN header is treated as the external VLAN.
- If the `CTRL_EXT.EXT_VLAN` bit is set the I350 expects that any transmitted packet to have at least the external VLAN added by the software. For those packets where an external VLAN is not present, any offload that relates to inner fields to the EtherType may not be provided.
- If the regular VLAN is inserted using the switch based VLAN insertion mechanism (see [Section 7.8.3.8.2.2](#)) or from the descriptor (see [Section 7.4.3.1](#)), and the packet does not contain an external VLAN, the packet will be dropped, and if configured, the queue from which the packet was sent will be disabled.

## 7.4.5.2 Receive Behavior With External VLAN

When a port of the I350 is working in this mode, the I350 assumes that all packets received by this port have at least one VLAN, including packet received or sent on the manageability interface.

One exception to this rule are flow control PAUSE packets which are not expected to have any VLAN. Other packets may contain no VLAN, however a received packet that does not contain the first VLAN is forwarded to the host but filtering and offloads are not applied to this packet.

See [Table 7-56](#) for the supported receive processing functions when the device is set to “Double VLAN” mode.

Stripping of VLAN is done on the second VLAN if it exists. All the filtering functions of the I350 ignore the first VLAN in this mode.

The presence of a first VLAN tag is indicated it in the `RDESC.STATUS.VEXT` bit.

Queue assignment of the Rx packets is not affected by the external VLAN header. It may depend on the internal VLAN, MAC address or any upper layer content as described in [Section 7.1.1](#).

**Table 7-56 Receive Processing in Double VLAN Mode**

| VLAN Headers          | Status.VEXT   | Status.VP | Packet Parsing        | Rx offload functions |
|-----------------------|---------------|-----------|-----------------------|----------------------|
| External and internal | 1             | 1         | +                     | +                    |
| Internal Only         | Not supported |           |                       |                      |
| V-Ext.                | 1             | 0         | +                     | +                    |
| None <sup>1</sup>     | 0             | 0         | + (flow control only) | -                    |

1. A few examples for packets that may not carry any VLAN header may be: Flow control and Priority Flow Control; LACP; LLDP; GMRP; 802.1x packets

## 7.5 Configurable LED Outputs

The I350 implements 4 output drivers intended for driving external LED circuits per port. Each LAN device provides an independent set of LED outputs - these pins and their function are bound to a specific LAN device. Each of the four LED outputs can be individually configured to select the particular event, state, or activity, which is indicated on that output. In addition, each LED can be individually configured for output polarity as well as for blinking versus non-blinking (steady-state) indication.

The configuration for LED outputs is specified via the *LEDCTL* register. Furthermore, the hardware-default configuration for all the LED outputs, can be specified via EEPROM fields, thereby supporting LED displays configurable to a particular OEM preference.

Each of the 4 LED's might be configured to use one of a variety of sources for output indication. The MODE bits control the LED source as described in [Table 7-57](#).

The IVRT bits allow the LED source to be inverted before being output or observed by the blink-control logic. LED outputs are assumed to normally be connected to the negative side (cathode) of an external LED.

The BLINK bits control whether the LED should be blinked (on for 200ms, then off for 200ms) while the LED source is asserted. The blink control might be especially useful for ensuring that certain events, such as ACTIVITY indication, cause LED transitions, which are sufficiently visible by a human eye.

**Note:** When LED Blink mode is enabled the appropriate LED Invert bit should be set to 0b.

The LINK/ACTIVITY source functions slightly different from the others when BLINK is enabled. The LED is off if there is no LINK, on if there is LINK and no ACTIVITY, and blinking if there is LINK and ACTIVITY.

The dynamic LED modes (FILTER\_ACTIVITY, LINK/ACTIVITY, COLLISION, ACTIVITY, PAUSED) should be used with LED Blink mode enabled.

### 7.5.1 MODE Encoding for LED Outputs

[Table 7-57](#) lists the MODE encoding for LED outputs used to select the desired LED signal source for each LED output.

**Table 7-57 Mode Encoding for LED Outputs**

| Mode  | Selected Mode   | Source Indication                                                                                          |
|-------|-----------------|------------------------------------------------------------------------------------------------------------|
| 0000b | LINK_10/1000    | Asserted when either 10 or 1000 Mb/s link is established and maintained.                                   |
| 0001b | LINK_100/1000   | Asserted when either 100 or 1000 Mb/s link is established and maintained.                                  |
| 0010b | LINK_UP         | Asserted when any speed link is established and maintained.                                                |
| 0011b | FILTER_ACTIVITY | Asserted when link is established and packets are being transmitted or received that passed MAC filtering. |
| 0100b | LINK/ACTIVITY   | Asserted when link is established and when there is no transmit or receive activity.                       |
| 0101b | LINK_10         | Asserted when a 10 Mb/s link is established and maintained.                                                |
| 0110b | LINK_100        | Asserted when a 100 Mb/s link is established and maintained.                                               |
| 0111b | LINK_1000       | Asserted when a 1000 Mb/s link is established and maintained.                                              |

**Table 7-57 Mode Encoding for LED Outputs (Continued)**

| Mode  | Selected Mode | Source Indication                                                                                                              |
|-------|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| 1000b | SDP_MODE      | LED activation is a reflection of the SDP signal. SDP0, SDP1, SDP2, SDP3 are reflected to LED0, LED1, LED2, LED3 respectively. |
| 1001b | FULL_DUPLEX   | Asserted when the link is configured for full duplex operation (de-asserted in half-duplex).                                   |
| 1010b | COLLISION     | Asserted when a collision is observed.                                                                                         |
| 1011b | ACTIVITY      | Asserted when link is established and packets are being transmitted or received.                                               |
| 1100b | BUS_SIZE      | Asserted when the I350 detects a 4-lane PCIe connection.                                                                       |
| 1101b | PAUSED        | Asserted when the I350's transmitter is flow controlled.                                                                       |
| 1110b | LED_ON        | Always high (Asserted)                                                                                                         |
| 1111b | LED_OFF       | Always low (De-asserted)                                                                                                       |

## 7.6 Memory Error Correction and Detection

The I350 main internal memories are protected by error correcting code or parity bits. Large memories or critical memories are protected by an error correcting code (ECC). Smaller memories are protected either with an error correcting code (ECC for critical memories) or by parity.

The I350 reports parity errors in the *PEIND* register according to the region in which the parity error occurred (PCIe, DMA, LAN Port or Management). An interrupt is issued via the *ICR.FER* bit on occurrence of a parity error. Parity error interrupt generation per region can be masked via the *PEINDM* register.

Additional per region granularity in parity or ECC enablement and reporting of parity error or ECC parity correction occurrence is supported in the following registers:

1. PCIe region:
  - a. The *PCIEERRCTL* and *PCIEECCCTL* registers enable parity checks and ECC parity correction respectively in the various rams in the PCIe region.
  - b. The *PCIEERRSTS* and *PCIEECCSTS* registers report parity error and ECC parity correction occurrence in the various rams in the PCIe region. Only parity errors that were not corrected by the ECC circuitry are reported by asserting the *PEIND.pcie\_parity\_fatal\_ind* bit and the *ICR.FER* bit. Parity errors that were corrected by the internal ECC circuit do not generate an interrupt but are logged in the *PCIEECCSTS* register.
2. DMA region:
  - a. The *DTPARC* and *DRPARC* registers enable parity checks while the *DDECCC*, *RPBECCSTS* and *TPBECCSTS* registers enable ECC parity correction in the various rams in the DMA region.
  - b. The *DTPARS* and *DRPARS* registers report detection of parity errors while the *DDECCS*, *RPBECCSTS* and *TPBECCSTS* registers report occurrence of ECC parity correction events in the various rams in the DMA region. Only parity errors that were not corrected are reported by setting the *PEIND.dma\_parity\_fatal\_ind* bit and the *ICR.FER* bit. Parity errors that were corrected by the internal ECC circuitry don't generate an interrupt but are logged in the *DDECCS*, *RPBECCSTS* and *TPBECCSTS* registers.
3. LAN Port region:
  - a. The *LANPERRCTL* register enables parity checks in the various rams in the LAN Port region.
  - b. The *LANPERRSTS* register reports detection of parity errors. The parity errors that were not corrected are reported via the *PEIND.lanport\_parity\_fatal\_ind* bit and the *ICR.FER* bit.
  - c.

**Notes:**

1. An interrupt to the Host is generated on occurrence of a fatal memory error if the appropriate mask bits in the *PEINDM* register are set and the *IMS.FER* Mask bit is set.
2. All Parity error checking can be disabled via the *GPAR\_EN* bit in the *Initialization Control Word 1* EEPROM word (See [Section 6.2.2](#)) or by clearing the *PCIEERRCTL.GPAR\_EN* bit (See [Section 8.23.11](#)).

## 7.6.1 Software Recovery From Parity Error Event

If a parity error was detected in one of the internal control memories of the DMA, PCIe or LAN port clusters, the consistency of the receive/transmit flow can not be guaranteed any more. In this case the traffic on the PCIe interface is stopped, since this is considered a fatal error.

If a parity error is detected on the Manageability cluster, PCIe traffic is not affected but an internal reset to the Manageability cluster is generated.

**Note:** An internal Firmware reset is issued, if enabled by the *PARITY\_ERR\_RST\_EN* bit in the *Common Firmware Parameters 2* EEPROM word, following detection of a parity error in the Management cluster.

To recover from a parity error event Software should initiate the following actions depending on the region in which the parity error occurred.

### 7.6.1.1 Recovery from PCIe Parity Error Event

To recover from a parity error condition in the PCIe region Software driver should:

1. Issue a Device Reset by asserting the *CTRL.RST* bit.
2. wait at least 3 milliseconds after setting *CTRL.RST* bit before attempting to check if the bit was cleared or before attempting to access any other register.
3. Initiate the master disable algorithm as defined in [Section 5.2.3.3](#).
4. Clear the PCIe parity error status bits that were set in the *PCIEERRSTS* register.
5. Re-initialize the port.

### 7.6.1.2 Recovery from DMA Parity Error Event

To recover from a parity error condition in the DMA region Software driver should issue a SW reset by asserting the *CTRL.RST* bit as specified in [Section 4.3.1](#) and re-initializing the port.

### 7.6.1.3 Recovery from LAN Port Parity Error Event

To recover from a parity error condition in the LAN port region Software driver should take the actions depicted in [Section 8.23.16](#) (*LANPERRSTS* register) according to the ram that failed.

## 7.7 CPU affinity Features

### 7.7.1 Direct Cache Access (DCA)

#### 7.7.1.1 DCA Description

Direct Cache Access (DCA) is a method to improve network I/O performance by placing some posted inbound writes indirectly within CPU cache. DCA requires that memory writes go to host memory and then the processor prefetch the cache lines specified by the memory write. Through research and experiments, DCA has been shown to reduce CPU Cache miss rates significantly.

**Figure 7-19** Diagram of DCA Implementation on FSB System

As shown in Figure 7-19, DCA provides a mechanism where the posted write data from an I/O device, such as an Ethernet NIC, can be placed into CPU cache with a hardware pre-fetch. This mechanism is initialized upon a power good reset. A software device driver for the I/O device configures the I/O device for DCA and sets up the appropriate DCA target ID for the device to send data. The device will then encapsulate that information in PCIe TLP headers, in the *TAG* field, to trigger a hardware pre-fetch by the MCH /IOH to the CPU cache.

DCA implementation is controlled by separated registers (*RXCTL* and *TXCTL*) for each receive and transmit queue. In addition, a *DCA Enable* bit can be found in the *DCA\_CTRL* register, and a *DCA\_ID* register can be found for each port, in order to make visible the function, device, and bus numbers to the driver.

The *RXCTL* and *TXCTL* registers can be written by software on the fly and can be changed at any time. When software changes the register contents, hardware applies changes only after all the previous packets in progress for DCA have been completed.

However, in order to implement DCA, the I350 has to be aware of the Crystal Beach version used. Software driver must initialize the I350 to be aware of the Crystal Beach version. A register named *DCA\_CTRL* is used in order to properly define the system configuration.

There are 2 modes for DCA implementation:

1. Legacy DCA: The DCA target ID is derived from CPU ID.
2. DCA: The DCA target ID is derived from APIC ID.

The software driver selects one of these modes through the DCA\_mode register.

The details of both modes are described below.

## 7.7.1.2 Details of Implementation

### 7.7.1.2.1 PCIe Message Format for DCA

Figure 7-20 shows the format of the PCIe message for DCA.

Figure 7-20 PCIe Message Format for DCA

The DCA preferences field has the following formats.

Table 7-58 Legacy DCA Systems

| Bits | Name           | Description                                                |
|------|----------------|------------------------------------------------------------|
| 0    | DCA indication | 0b: DCA disabled<br>1b: DCA enabled                        |
| 4:1  | DCA Target ID  | The DCA Target ID specifies the target cache for the data. |
| 7:5  | Reserved       | Reserved                                                   |

**Table 7-59 DCA Systems**

| Bits | Name          | Description                 |
|------|---------------|-----------------------------|
| 7:0  | DCA target ID | 0000.0000b: DCA is disabled |

**Note:** All functions within the I350 have to adhere to the “tag encoding” rules for DCA writes. Even if a given function is not capable of DCA, but other functions are capable of DCA, memory writes from the non-DCA function must set the *Tag* field to “00000000”.

## 7.7.2 TLP Process Hints (TPH)

The I350 supports the TPH capability defined in the PCI Express specification (See [Section 9.6.3](#)). It does not support Extended TPH requests.

On the PCIe link existence of a TLP Process Hint (TPH) is indicated by setting the TH bit in the TLP header. Using the PCIe TLP Steering Tag (ST) and Processing Hints (PH) fields, the I350 can provide hints to the root complex about the destination (socket ID) and about data access patterns (locality in Cache), when executing DMA memory writes or read operations. Supply of TLP Processing Hints facilitates optimized processing of transactions that target Memory Space.

The I350 supports a steering table with 8 entries in the PCIe TPH capability structure (See [Section 9.6.5.4](#)). The PCIe Steering table can be used by Software to provide Steering Tag information to the Device via the *TXCTL.CPUID* and *RXCTL.CPUID* fields.

To enable TPH usage:

1. For a given function, the *TPH Requester Enable* bit in the PCIe configuration *TPH Requester Control Register* should be set.
2. Appropriate TPH Enable bits in *RXCTL* or *TXCTL* registers should be set.

**Note:** In SR-IOV mode, the *TPH Requester Enable* bit of the VFs does not gate the emission of hints. Thus in VFs, TPH Enable bits in *RXCTL* or *TXCTL* registers should be set only if the *TPH Requester Enable* bit in the config space of the VF is set.

3. Processing hints should be programmed in the *DCA\_CTRL.Desc\_PH* and *DCA\_CTRL.Data\_PH* Processing hints (PH) fields.
4. Steering information should be programmed in the CPUID fields in the *RXCTL* and *TXCTL* registers.

The Processing hints (PH) and Steering Tags (ST) are set according to the characteristics of the traffic as described in [Table 7-60](#).

**Note:** In order to enable TPH usage, all the memory reads are done without setting any of the byte enable bits.

Per queue, the DCA and TPH features are exclusive. Software can enable either the DCA feature or the TPH feature for a given queue.

## 7.7.2.1 Steering Tag and Processing Hint Programming

The following table describes how the Steering tag (socket ID) and Processing hints are generated and how TPH operation is enabled for different types of DMA traffic.

**Table 7-60 Steering tag and Processing hint programming**

| Traffic type                                      | ST Programming           | PH value                      | Enable                                                               |
|---------------------------------------------------|--------------------------|-------------------------------|----------------------------------------------------------------------|
| Transmit descriptor write back or head write back | TXCTL.CPUID <sup>1</sup> | DCA_CTRL.Desc_PH <sup>2</sup> | <i>Tx Descriptor Writeback TPH EN</i> field in TXCTL.                |
| Receive data buffers write                        | RXCTL.CPUID <sup>1</sup> | DCA_CTRL.Data_PH <sup>3</sup> | <i>RX Header TPH EN</i> or <i>Rx Payload TPH EN</i> fields in RXCTL. |
| Receive descriptor writeback                      | RXCTL.CPUID <sup>1</sup> | DCA_CTRL.Desc_PH <sup>2</sup> | <i>RX Descriptor Writeback TPH EN</i> field in RXCTL.                |
| Transmit descriptor fetch                         | TXCTL.CPUID <sup>4</sup> | DCA_CTRL.Desc_PH <sup>2</sup> | <i>Tx Descriptor Fetch TPH EN</i> field in TXCTL.                    |
| Receive descriptor fetch                          | RXCTL.CPUID <sup>2</sup> | DCA_CTRL.Desc_PH <sup>2</sup> | <i>Rx Descriptor fetch TPH EN</i> field in RXCTL.                    |
| Transmit packet read                              | TXCTL.CPUID <sup>2</sup> | DCA_CTRL.Data_PH <sup>3</sup> | <i>Tx Packet TPH EN</i> field in TXCTL.                              |

1. the driver should always set bits [7:3] to zero and place Socket ID in bits [2:0].
2. Default is 00b (Bidirectional data structure).
3. Default is 10b (Target).
4. the hints are always zero.

## 7.8 Virtualization

### 7.8.1 Overview

I/O virtualization is a mechanism to share I/O resources among several consumers. For example, in a virtual system, multiple operating systems are loaded and each executes as though the whole system's resources were at its disposal. However, for the limited number of I/O devices, this presents a problem because each operating system might be in a separate memory domain and all the data movement and device management has to be done by a VMM (Virtual Machine Monitor). VMM access adds latency and delay to I/O accesses and degrades I/O performance. Virtualized devices are designed to reduce the burden of VMM by making certain functions of an I/O device shared and thus can be accessed directly from each guest operating system or Virtual Machine (VM).

Two modes to support operation in a Virtualized environment were implemented in previous products:

1. Direct assignment of part of the port resources to different guest OSes using the PCI sig SR-IOV standard. Also known as "Native mode" or pass through mode. This mode is referenced as IOV mode through this chapter
2. Central management of the networking resources by an IOVM or by the VMM. Also known as software switch acceleration mode. This mode is referenced as Next Generation VMDq mode.

The I350 supports fully Next Generation VMDq mode and SR-IOV.

In a virtualized environment, the I350 serves up to 8 virtual machines (VMs) per port. The I350's 8 queues can be accessed by 8 different VMs if configured properly. When the I350 is enabled for multiple queue direct access for VMs, it becomes a VMDq device.

**Note:** Most configuration and resources are shared across queues. System software must resolve any conflicts in configuration between the VMs.

The virtualization offloads capabilities provided by the I350 apart from the replication of functions defined in the PCI-sig IOV spec are also part of Next Generation VMDq.

An hybrid model, where part of the virtual machines are assigned a dedicated share of the port and the other ones are serviced by an IOVM should also be supported. However, in this case the offloads provided to the software switch might be more limited. This model can be used when parts of the VMs runs OSES for which VF drivers are available and thus can benefit from IOV and others runs older OSES for which VF drivers are not available and are serviced by an intermediary. In this case, the IOVM or VMM is assigned one VF and receives all the packets with MAC addresses of the VMs behind it.

The following section describes the support the I350 provides for virtualization. This chapter assumes a single root implementation of IOV and no support for multi root.

### 7.8.1.1 Direct Assignment Model

The direct assignment support in the I350 is built according to the software model defined by the SR-IOV spec:

It is assumed that one of the software drivers sharing the port hardware behaves as a master driver (Physical Function or PF driver). This driver is responsible for the initialization and the handling of the common resources of the port. All the other drivers might read part of the status of the common parts but can not change it. The PF driver might run either in the VMM or in some service operating system. It might be part of an IOVM or part of a dedicated service operating system.

In addition, part of the non time critical tasks are also handled by the PF driver. For example, access to CSR through the I/O space or access to the configuration space are available only through the master interface. Time critical CSR space like control of the Tx and Rx queue or interrupt handling is replicated per VF, and directly accessible by the VF driver.

**Note:** In some systems with a Thick Hypervisor, the Service operating system might be an integral part of the VMM - for these systems, each reference to the service operating system in the document below refers to the VMM.

#### 7.8.1.1.1 Rationale

Direct assignment purpose is to enable each of the virtual machines to receive and transmit packets with minimum of overhead. The non time critical operations such as init and error handling can be done via the PF driver. In addition, it is important that the VMs can operate independently with minimal disturbance. It is also preferable that the VM interface to the hardware should be as close as possible to the native interface in non virtualized systems in order to minimize the software development effort.

The main time critical operations that require direct handling by the VM are:

1. Maintenance of the data buffers and descriptor rings in host memory. In order to support this, the DMA accesses of the queues associated to a VM should be identified as such on the PCIe bus using a different requester ID.
2. Handling of the hardware ring (tail bump and head updates)
3. Interrupts handling.

The capabilities needed to provide independence between VMs are:

1. Per VM reset and enable capabilities.

2. TX Rate control
3. Allocation of separate CSR space per VM. This CSR space is organized as close as possible to the regular CSR space to allow sharing of the base driver code.

**Note:** The rate control and VF enable capabilities are controlled by the PF.

### 7.8.1.2 Virtualized System Overview

The following drawings describe the various elements involved in the I/O process in a virtualized system. [Figure 7-21](#) describes the flow in software Next Generation VMDq operation mode and [Figure 7-22](#) the flow in IOV mode.

This document assumes that in IOV mode, the driver on the guest operating system is aware that it works in a virtual system (para-virtualized) and there is a channel between each of the virtual machine drivers and the PF driver allowing message passing such as configuration request or interrupt messages. This channel might use the mailbox system implemented in the I350 or any other method provided by the VMM vendor.

**Figure 7-21 IOVM (VMDq) System**

**Figure 7-22 SR-IOV Based System**

## 7.8.1.3 VMDq Supported Features

The I350 supports a superset of the VMDq virtualization features supported in the 82576 and in the 82580. The following table compares the virtualization features in the three products.

**Table 7-61 I350 Versus the 82576 versus 82580 VMDq Support**

| Feature                             | I350 VMDq Support           | 82576 VMDq Support                          | 82580 VMDq Support          |
|-------------------------------------|-----------------------------|---------------------------------------------|-----------------------------|
| Queues                              | 8                           | 16                                          | 8                           |
| Pools                               | 8 (single queue)            | 8                                           | 8 (single queue)            |
| MAC addresses                       | 32                          | 24                                          | 24                          |
| Queuing to pool method              | SA or VLAN or (SA and VLAN) | SA or VLAN or (SA and VLAN)                 | SA or VLAN or (SA and VLAN) |
| RSS in pool                         | RSS not supported in VMDq   | Common redirection table - enable per pool. | RSS not supported in VMDq   |
| VM to VM Switching                  | Yes                         | Yes                                         | No                          |
| Broadcast and multicast Replication | Yes                         | Yes                                         | Yes (Receive only)          |
| MAC and VLAN Anti spoof protection  | Yes                         | Yes                                         | No                          |
| VLAN filtering                      | Global and per pool         | Global and per pool                         | Global and per pool         |
| Drop if no pool                     | Yes                         | Yes                                         | Yes                         |
| per pool statistics                 | Yes                         | Yes                                         | Yes                         |
| Per pool offloads                   | Yes                         | Yes                                         | Yes                         |
| Mirroring                           | Yes                         | Yes                                         | Yes (Receive only)          |
| Long packet filtering               | Global and per pool         | Global and per pool                         | Global and per pool         |
| Storm Control                       | Yes                         | Yes                                         | Yes                         |
| Promiscuous modes per VM            | VLAN, Multicast, Unicast    | Multicast                                   | Multicast                   |

## 7.8.2 PCI Sig IOV Support

### 7.8.2.1 IOV Concepts

IOV defines the following entities in relation to I/O virtualization:

1. Virtual Image (VI): A virtual machine to which a part of the I/O resources is assigned. Also known as a VM.
2. I/O Virtual Intermediary (IOVI) or I/O Virtual Machine (IOVM): A special virtual machine that owns the physical device and is responsible for the configuration of the physical device.
3. End point (EP): The physical device that might contain a few physical functions - in our case, the I350.
4. Physical function (PF): A function representing a Physical instance - in our case, one port. The PF driver is responsible for the configuration and management of the shared resources in the function.
5. Virtual function (VF): A part of a PF assigned to a VI.

## 7.8.2.2 Configuration Space Replication

The IOV working group defines the configuration space of the Virtual functions as a mirror of the Physical function configuration space with the exception of some fields which are implemented per VF. The I350 complies with the SR-IOV specification. This section describes how the I350 implements the configuration space for virtual functions as defined in the specification.

Details of the configuration space for virtual functions can be found in [Section 9.7](#).

### 7.8.2.2.1 Legacy PCI Config Space

The legacy configuration space is allocated to the PF only and emulated for the VFs. A separate set of BARs and one Bus master enable bit is allocated to the whole set of VFs.

All the legacy error reporting bits are emulated for the VF. See [Section 7.8.2.4](#) for details.

### 7.8.2.2.2 Memory BARs Assignment

The IOV spec defines a fixed stride for all the VF BARs, so that each VF can be allocated part of the memory BARs at a fixed stride from the a basic set of BARs. In this method only two decoders per replicated BAR per PF are required and the BARs reflected to the VF are emulated by the VMM

The only BARs that are useful for the VFs are BAR0 & BAR3, thus only those are replicated.

The following table describes the existing BARs and the stride used for the VFs:

**Table 7-62 VF BARs in the I350**

| BAR | Type | Usage                            | Requested Size Per VF |
|-----|------|----------------------------------|-----------------------|
| 0   | Mem  | CSR space                        | min(16K, page size)   |
| 1   | Mem  | High word of CSR space address   | N/A                   |
| 2   | N/A  | Not used                         | N/A                   |
| 3   | Mem  | MSI-X                            | min(16K, page size)   |
| 4   | Mem  | High word of MSI-X space address | N/A                   |
| 5   | N/A  | Not used                         | N/A                   |

BAR0 of the VFs are a sparse version of the original PF BAR and includes only the register relevant to the VF. For more details see [Section 8.27](#) and [Section 8.28](#).

The following figure describes the different BARs in an IOV enabled system:

**Figure 7-23 Memory BAR Allocation to VFs**

### 7.8.2.2.3 Capability Structures

#### 7.8.2.2.3.1 PCIe capability structure

The PCIe capability structures are shared between the PF & the VFs. The only replicated bits are:

1. Transaction pending
2. Enable No Snoop
3. Enable Relaxed Ordering

4. Initiate FLR
5. Error reporting bits. See [Section 7.8.2.4](#) for details.

#### **7.8.2.2.3.2 MSI and MSI-X Capabilities**

Both MSI & MSI-X are implemented in the PF in the I350. MSI-X vectors can be assigned per VF. MSI is not supported for the VFs.

See [Section 9.7](#) for more details of the MSI-X and PBA tables implementation.

#### **7.8.2.2.3.3 VPD Capability**

VPD is implemented only once and is accessible only from the PF.

#### **7.8.2.2.3.4 Power Management Capability**

PCI SIG SR-IOV specification makes VF power management optional. The I350 does not support power management in VFs.

#### **7.8.2.2.4 Extended Capability Structures**

#### **7.8.2.2.5 Serial ID**

The serial ID capability is not supported in VFs.

#### **7.8.2.2.6 Error Reporting Capabilities (Advanced & Legacy)**

All the bits in this capability structure is implemented only for the PF. The VMs see an emulated version of this. See [Section 7.8.2.4](#) for details.

### **7.8.2.3 Function Level Reset (FLR) Capability**

The *FLR* bit is required per VF. Setting of this bit resets only the part of the logic dedicated to the specific VF and do not influence the shared part of the port. This reset should disable the queues, disable interrupts and stop receive and transmit process per VF.

Setting the *PF FLR* bit resets the entire function.

### **7.8.2.4 Error Reporting**

Error reporting includes legacy error reporting and AER (advanced error reporting or role based) capability.

The legacy error management includes the following functions:

1. Error capabilities enablement. These are set by the PF for all the VFs. Narrower error reporting for a given VM can be achieved by filtering of the errors by the VMM. This includes:
  - a. SERR# Enable
  - b. Parity Error Response
  - c. Correctable Reporting Enable

- d. Non-Fatal Reporting Enable
  - e. Fatal Reporting Enable
  - f. UR Reporting Enable
2. Error status in the config space. These should be set separately for each VF. This includes:
- a. Master Data Parity Error
  - b. Signaled Target Abort
  - c. Received Target Abort
  - d. Master Abort
  - e. SERR# Asserted
  - f. Detected Parity Error
  - g. Correctable Error Detected
  - h. Non-Fatal Error Detected
  - i. Unsupported Request Detected

AER capability includes the following functions:

1. Error capabilities enablement. The Error Mask, and Severity bits are set by the PF for all the VFs. Narrower error reporting for a given VM can be achieved by filtering of the errors by the VMM. These includes:
  - a. Uncorrectable Error Mask Register
  - b. Uncorrectable Error Severity Register
  - c. Correctable Error Mask Register
  - d. ECRC Generation Enable
  - e. ECRC Check Enable
2. Non-Function Specific Errors Status in the config space.
  - a. Non-Function Specific Errors are logged in the PF
  - b. Error logged in one register only
  - c. VI avoids touching all VFs to clear device level errors
  - d. The following errors are not function specific
    - All Physical Layer errors
    - All Link Layer errors
    - ECRC Fail
    - UR, when caused by no function claiming a TLP
    - Receiver Overflow
    - Flow Control Protocol Error
    - Malformed TLP
    - Unexpected Completion
3. Function Specific Errors Status in the config space.
  - a. Allows Per VF error detection and logging
  - b. Help with fault isolation
  - c. The following errors are function specific
    - Poisoned TLP received
    - Completion Timeout

- Completer Abort
  - UR, when caused by a function that claims a TLP
  - ACS Violation
4. Error logging. Each VF has its own header log.
  5. Error messages. In order to ease the detection of the source of the error, the error messages should be emitted using the requester ID of the VF in which the error occurred.

### 7.8.2.5 ARI & IOV Capability Structures

In order to allow more than 8 functions per end point without requesting an internal switch, as usually needed in virtualization scenarios, the PCI sig defines the Alternative Routing ID (ARI) capability structure. This is a capability that allows an interpretation of the Device & Function fields as a single identification of a function within the bus. In addition a new structure used to support the IOV capabilities reporting and control is defined. Both structures are described in sections 9.6.3 & 9.6.4. See next section for details on the RID allocation to VFs.

### 7.8.2.6 Requester ID Allocation

The requester ID allocation of the VF is done using the *Offset* field in the IOV structure. This field should be replicated per VF and is used to do the enumeration of the VFs.

Each PF includes an offset to the first associated VF. This pointer is a relative offset to the BDF of the first VF. The *Offset* field is added to PF's requester ID to determine requester ID of the next VF. An additional field in the IOV capability structure describes the distance between two consecutive VF's requester ID.

#### 7.8.2.6.1 Bus-Device-Function Layout

##### 7.8.2.6.1.1 ARI Mode

The ARI mode allows interpretation of the device ID part of the RID as part of the function ID inside a device. Thus a single device can span up to 256 functions. In order to ease the decoding, the 2 least significant bits of the function number points to the physical port number. The next bits indicate the VF number. The following table describes the VF requester IDs.

**Table 7-63 RID Per VF - ARI Mode**

| Port | VF# | B,D,F  | Binary      | Notes                              |
|------|-----|--------|-------------|------------------------------------|
| 0    | PF  | B,0,0  | B,00000,000 | PF #0                              |
| 1    | PF  | B,0,1  | B,00000,001 | PF #1                              |
| 2    | PF  | B,0,0  | B,00000,010 | PF #2                              |
| 3    | PF  | B,0,1  | B,00000,011 | PF #3                              |
| 0    | 0   | B,16,0 | B,10000,000 | Offset to first VF from PF is 128. |
| 1    | 0   | B,16,1 | B,10000,001 |                                    |
| 2    | 0   | B,16,2 | B,10000,010 |                                    |
| 3    | 0   | B,16,3 | B,10000,011 |                                    |
| 0    | 1   | B,16,4 | B,10000,100 |                                    |
| 1    | 1   | B,16,5 | B,10000,101 |                                    |
| 2    | 1   | B,16,6 | B,10000,110 |                                    |

**Table 7-63 RID Per VF - ARI Mode (Continued)**

| Port | VF# | B,D,F  | Binary      | Notes |
|------|-----|--------|-------------|-------|
| 3    | 1   | B,16,7 | B,10000,111 |       |
| ...  |     |        |             |       |
| 0    | 7   | B,19,4 | B,10011,100 |       |
| 1    | 7   | B,19,5 | B,10011,101 |       |
| 2    | 7   | B,19,6 | B,10011,110 |       |
| 3    | 7   | B,19,7 | B,10011,111 | Last  |

### 7.8.2.6.1.2 Non ARI Mode

When ARI is disabled, non zero devices in the first bus can not be used, thus a second bus is needed to provide enough requester IDs. In this mode, the RID layout is as follow:

**Table 7-64 RID Per VF - Non ARI Mode**

| Port | VF# | B,D,F    | Binary        | Notes                              |
|------|-----|----------|---------------|------------------------------------|
| 0    | PF  | B,0,0    | B,00000,000   | PF #0                              |
| 1    | PF  | B,0,1    | B,00000,001   | PF #1                              |
| 2    | PF  | B,0,2    | B,00000,010   | PF #2                              |
| 3    | PF  | B,0,3    | B,00000,011   | PF #3                              |
| 0    | 0   | B+1,16,0 | B+1,10000,000 | Offset to first VF from PF is 384. |
| 1    | 0   | B+1,16,1 | B+1,10000,001 |                                    |
| 2    | 0   | B+1,16,2 | B+1,10000,010 |                                    |
| 3    | 0   | B+1,16,3 | B+1,10000,011 |                                    |
| 0    | 1   | B+1,16,4 | B+1,10000,100 |                                    |
| 1    | 1   | B+1,16,5 | B+1,10000,101 |                                    |
| 2    | 1   | B+1,16,6 | B+1,10000,110 |                                    |
| 3    | 1   | B+1,16,7 | B+1,10000,111 |                                    |
| ...  |     |          |               |                                    |
| 0    | 7   | B+1,19,4 | B+1,10011,100 |                                    |
| 1    | 7   | B+1,19,5 | B+1,10011,101 |                                    |
| 2    | 7   | B+1,19,6 | B+1,10011,110 |                                    |
| 3    | 7   | B+1,19,7 | B+1,10011,111 | Last                               |

**Note:** When the device ID of a physical function changes (because of LAN disable or *FACTPS.LAN Function Sel* settings), the VF device IDs changes accordingly.

## 7.8.2.7 Hardware Resources Assignment

The main resources to allocate per VM are queues and interrupts. The assignment is a static one. If a VM requires more resources, it might be allocated more than one VF. In this case, each VF gets a specific MAC address/VLAN tag in order to allow forwarding of incoming traffic. The two VFs are then teamed in software.

### 7.8.2.7.1 Physical Function Resources

A possible use of the Physical function is for configuration setting without transmit and receive capabilities. In this case it is not allocated any queues and is allocated one MSI-X vector.

Physical function have access to all the resources of all the virtual machines but it is not expected to make use of resources allocated to active Virtual Functions.

#### 7.8.2.7.2 Assignment of Queues to VF

Each VF is assigned one queue. Queue N is assigned to VF N.

#### 7.8.2.7.3 Assignment of MSI-X Vectors to VF.

MSI-X vectors are used for three purposes:

1. Differentiation of interrupt causes that avoids the need to read an interrupt cause register.
2. Assignment of different interrupt handling to different CPUs.
3. The implementation of interrupts in the I350 adds another use of allowing different interrupt moderation rates.

The I350 supports 3 MSI-X vectors per PF. The interrupt causes mapped to these MSI-X vectors via the *VTIVAR* and *VTIVAR\_MISC* registers are RX traffic interrupt, TX traffic interrupt and Mail Box interrupt. The VF can vary the interrupt rates on these queues using the *VTEITR0*, *VTEITR1* and *VTEITR2* registers.

#### 7.8.2.7.4 VF Resource Summary

The I350 supports 8 VFs per port, each VF can utilize 1 queue pair (Tx/Rx) per VF and 3 MSI-X vectors per VM. If the amount of VFs supported is less than 8, the available resources can be used by the PF.

### 7.8.2.8 CSR Organization

The CSR of the NIC can be divided to three types:

1. Global Configuration registers that should be accessible only to the PF (such as link control, LED control, etc.). This type of registers includes also all the debug features such as the mapping of the packet buffers and is responsible for most of the CSR area requested by the NIC. This includes per VF configuration parameters that can be set by the PF without performance impact.
2. Per queue parameters that should be replicated per queue (head, tail, Rx buffer size, and DCA tag). These parameters are used both by a VF in an IOV system and by the PF in a non IOV mode.
3. Per VF parameters (per VF reset) interrupt enable. Multiple instances of these parameters are used only in an IOV system and only one instance is needed for non IOV systems.

In order to support IOV without distributing the current drivers operation in legacy mode, the following method is used:

1. The PF instance of BAR0 continues to contain the legacy and control registers. It is accessible only to the PF. The BAR allows access to all the resources including the VF queues and other VF parameters. However it is expected that the PF driver does not access these queues in IOV mode.
2. The VF instances of BAR0 provide control of the VF specific registers. These registers have the same relative mapping to BAR0 of the VF as the original BAR0 of the PF with the following exceptions:
  - a. Fields related to the shared resources are reserved.

- b. The VF queue related registers are mapped at the same relative location to BAR0 as the queue registers of the first queue (Queue 0) of the PF.
3. To supply backward compatibility for the IOV drivers, the PF/VF parameters block contains a partial register set as described in [Section 8.27](#) and [Section 8.28](#).

## 7.8.2.9 IOV Control

In order to control the IOV operation, the physical driver is provided with a set of registers. These includes:

1. The mailbox mechanism described below.
2. The switch and filtering control registers described in [Section 7.8.3.10](#).
3. VFLRE: register indicating that a VFLR reset occurred in one of the VFs (bitmap).
4. VFTE: Enables Tx traffic per VF. A VF Tx is disabled by an FLR to this VF until the PF enables it again. This allows the PF to block transmit process until the configurations for this VM are done.
5. VFRE: Enables Rx filtering per VF. A VF Rx is disabled by an FLR to this VF until the PF enables it again. This allows the PF to block the receive process until the configurations for this VM are done.

### 7.8.2.9.1 VF to PF Mailbox

The VF drivers and the PF driver requires some mean of communication between them. This channel can be used for the PF driver to send status updates to the VFs (link change, memory parity error, etc.) or for the VF to send requests to the PF (add to VLAN).

Such a channel can be implemented in software, but it requires enablement by the VMM vendors. In order to avoid the need for such an enablement, the I350 provides such a channel that allows direct communication between the two drivers.

The channel consists of a mailbox similar to the host interface currently defined between the software and the manageability. Each driver can then receive and indication (either poll or interrupt) when the other side wrote a message.

Assuming a max message size of 64 bytes (one cache line), RAM of 64 bytes x 8 VMs= 0.5 Kbyte is provided. [Table 7-65](#) shows how RAM is organized.

**Table 7-65 Mailbox Memory**

| RAM Address | Function | PF BAR 0 Mapping <sup>1</sup> | VF BAR 0 Mapping <sup>2</sup> |
|-------------|----------|-------------------------------|-------------------------------|
| 0 - 63      | VF0 ↔ PF | 0 - 63                        | VF0 + MBO                     |
| 64 - 127    | VF1 ↔ PF | 64 - 127                      | VF1 + MBO                     |
| ....        |          |                               |                               |
| 448 - 512   | VF7 ↔ PF | 448 - 512                     | VF7 + MBO                     |

1. Relative to mailbox offset
2. MBO = mailbox offset in VF CSR space

In addition for each VF, the *VFMailbox* & *PFMailbox* registers are defined in order to coordinate the transmission of the messages. These registers contains a semaphore mechanism to allow coordination of the mailbox usage.

The PF driver can decide which VFs are allowed to interrupt the PF to indicate a mailbox message using the *MBVFIMR* mask register.

The following flows describes the usage of the mailbox:

**Table 7-66 PF to VF Messaging Flow**

| Step | PF Driver                                                                                                                                                                | Hardware                                                 | VF #n Driver                                                                                    |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| 1    | Set <i>PFMailbox[n].PFU</i>                                                                                                                                              |                                                          |                                                                                                 |
| 2    |                                                                                                                                                                          | Set <i>PFU</i> bit if <i>PFMailbox[n].VFU</i> is cleared |                                                                                                 |
| 3    | Read <i>PFMailbox[n]</i> and check that <i>PFU</i> bit was set. Otherwise wait and go to step 1                                                                          |                                                          |                                                                                                 |
| 4    | Read <i>MBVFICR</i> register and verify that <i>VFREQ</i> bit of <i>VF[n]</i> is 0, otherwise clear <i>PFU</i> bit in <i>PFMailbox[n]</i> and respond to the VF message. |                                                          |                                                                                                 |
| 5    | Write message to relevant location in <i>VMBMEM</i>                                                                                                                      |                                                          |                                                                                                 |

| Step | PF Driver                                                                                       | Hardware                                                     | VF #n Driver                                                                                   |
|------|-------------------------------------------------------------------------------------------------|--------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| 8    | Set <i>PFMailbox[n].PFU</i> bit                                                                 |                                                              |                                                                                                |
| 9    |                                                                                                 | Set <i>PFU</i> bit if <i>PFMailbox[n].VFU</i> bit is cleared |                                                                                                |
| 10   | Read <i>PFMailbox[n]</i> and check that <i>PFU</i> bit was set. Otherwise wait and go to step 8 |                                                              |                                                                                                |
| 11   | Read the adequate message from <i>VMBMEM</i>                                                    |                                                              |                                                                                                |
| 12   | Clear <i>PFMailbox[n].PFU</i> bit and Set the <i>PFMailbox.ACK</i> bit                          |                                                              |                                                                                                |
| 13   |                                                                                                 | Indicate an interrupt to VF #n                               |                                                                                                |
| 14   |                                                                                                 |                                                              | Read <i>VFMailbox[n]</i> and check that the <i>ACK</i> bit was set. Otherwise wait and recheck |

The content of the message is hardware independent and can be fixed by the software.

The messages currently assumed by this specification are:

1. Registration to VLAN/Multicast packet/Broadcast packets - A VF can request to be part of a given VLAN or to get some multicast/broadcast traffic.
2. Reception of large packet - Each VF should notify the PF driver what is the largest packet size allowed in receive.
3. Get global statistics - A VF can request information from the PF driver on the global statistics.
4. Filter allocation request - A VF can request allocation of a filter for queuing/immediate interrupt support.
5. Global interrupt indication.
6. Indication of errors.

### 7.8.2.10 Interrupt Handling

Interrupts can be separated into two types:

1. Interrupts relevant to the behavior of each VM, including Rx & Tx packet sent indications, mailbox message and device status indications.
2. Interrupts relevant only to the handling of the shared resources. These are mainly error indications - such as packet buffer full and parity errors.

The first type of interrupts should be provided directly to the VM driver and the second type can be handled by the PF driver.

Interrupt control in the VF uses the same mechanism as the in the non virtualized case. The cause bits are independent and each VF can clear its own cause bits independently. The following registers are added per VF:

1. *VTEICR*, *VTEICS*, *VTEIMS*, *VTEIMC*, *VTEIAC*, *VTEIAM* with the following fields:
  - a. *RTxQ[1:0]*
  - b. Mailbox
2. *VTEITR0,1,2*.

3. VTIVAR & VTIVAR\_MISC for Mailbox.

#### 7.8.2.10.1 Low latency Interrupts

Low Latency Interrupts (LLI) are described in [Section 7.3.6](#). Several packet types generate LLI:

- A packet matching a 5-tuple filter assigned to a VF - Each VF can require from the PF driver an LLI for one of its flows.
- A packet matching a L2 EtherType filter - an LLI is generated to specific VFs (based on the queue assignment) that handle control traffic.
- A packet matching a certain VLAN priority - an LLI is generated to the target VF based on the queue assignment for the Rx packet

An AND condition on the VM number is added to the immediate interrupt decision in order to prevent a VM from requiring immediate interrupts for flows not owned by it and in order to allow a filter to apply only to a given VM. For example, assume a given VM would require immediate interrupts on packets with PSH flag set. The VM number filtering prevents other VM from receiving immediate interrupts on such packets.

#### 7.8.2.10.2 MSI-X

MSI-X tables are in BAR3. The MSI-X vectors might be used either as one big set of vectors in non IOV mode or as small sets allocated to VFs. In order to support both modes and save the need for duplication of the logic the first IOV vectors should be mapped as non IOV vectors also. The mapping of the vectors in IOV mode is described in [Section 8.28.49](#)

The PBA vector is replicated for the IOV case, as the saving in area is low and different per bit encoding is complicated.

#### 7.8.2.10.3 MSI

MSI implementation is optional in the IOV spec. The I350 doesn't support MSI in Virtual functions.

#### 7.8.2.10.4 Legacy Interrupt (INT-x)

Legacy interrupts are not supported in IOV mode.

### 7.8.2.11 DMA

#### 7.8.2.11.1 Requester ID

Each VF is allocated a requester ID. Each DMA request should use the RID of the VF that requested it. See [Section 7.8.2.6](#) for details.

#### 7.8.2.11.2 Sharing DMA Resources

The outstanding requests and completion credits are shared between all the VFs. The tags attached to read requests are assigned the same way they are today, although in VF systems tags can be re-used for different requester IDs.

#### 7.8.2.11.3 DCA and TPH

The DCA enable is common to all the devices (all PFs & VFs). Given a DCA enabled device, each VM might decide for each queue, on which type of traffic (data, headers, Tx descriptors, Rx descriptors) DCA should be asserted and what is the CPU ID assigned to this queue.

The TPH enable bit is set per VF. Each TPH enabled VM might decide for each queue, on which type of traffic (data, headers, Tx descriptors, Rx descriptors) DCA should be asserted and what is the CPU ID assigned to this queue.

**Note:** There are no plans to virtualize DCA or TPH in the root Complex. Thus the physical CPU ID should be used in the programming of the *CPUID* field.

## 7.8.2.12 Timers and Watchdog

### 7.8.2.12.1 TCP Timer

The TCP timer is available only to the PF. It might indicate an interrupt to the VFs via the mailbox mechanism.

### 7.8.2.12.2 IEEE 1588

IEEE 1588 is a per link function and thus is controlled by the PF driver. The VMs have access to the real time clock register.

### 7.8.2.12.3 Watchdog.

The watchdog was originally developed for pass-through NICs where virtualization is not an interesting use case. Thus, this functionality is used only by the PF.

### 7.8.2.12.4 Free Running Timer

The free running timer is a PF driver resource the VMs can access. This register is read only to all VF. It is reset only by the PCI reset.

## 7.8.2.13 Power Management and Wake-up

Power management, Wake-up and proxying is a PF resource and is not supported per VF.

## 7.8.2.14 Link Control

The link is a shared resource and as such is controllable only by the PF. This include PHY settings, speed and duplex settings, flow control settings, etc. The flow control packets are sent with the station MAC address stored in the EEPROM. The watermarks of the flow control process and the time-out value are also controllable by the PF only.

Double VLAN is a network setting and as such should be common to all VFs.

### 7.8.2.14.1 Special Filtering Options

Pass Bad packets is a debug feature. As such pass bad packet is available only to the PF. Bad packets is passed according to the same filtering rules of the regular packets. As it might cause guest operating systems to get unexpected packets, it should be used only for debug purposes of the whole system.

Reception of long packet is controlled separately per VM. As this impact the flow control thresholds, the PF should be made aware of the decision of all the VMs. Because of this, the setup of the large send packets is centralized by the PF and each VF might request this setting.

### 7.8.2.15 IOV Test Mode

In order to support testing of IOV features in non IOV enabled systems, such as OEM test-benches and early validation platform, a few features are added to the I350. The first one, is a possibility to allow VFs to use the PF Requester ID in their DMA transactions - this is done by setting the *GCR.ignore RID* bit. A second mode, allows some of the VF config bits to behave as copies of the *PF Config* bit - specifically the MSI-X interrupt enable, MSI-X interrupt mask and MBE bits. This is done by setting the *GCR.IOV test mode* bit.

An additional debug feature, is the possibility to access the config space of the PF and all the VFs via the regular CSR space. This mode allows the PF driver to access the IOV settings and the specific VFs config space. In addition, it allows access to the VFs config spaces for configuration even if the operating system and the BIOS are not aware of these functions existence. The different config spaces are accessible through the CIAA & CIAD register. The CIAA register contains the VF number and the offset of the register in the config space to access. It also contains a bit indicating if the VF configuration space are accessed through this mechanism or through regular configuration transactions. A read of the CIAD register will return the value of the config register pointed by the CIAA register. A value written to the CIAD register will be written to the config register pointed by the CIAA register.

#### 7.8.2.15.1 Allocation of memory space for IOV functions

If the BIOS didn't allocate memory for the IOV functions, the following flow may be used to allocate memory to the I350 virtual function:

1. In the EEPROM request some space for the serial flash BAR. This space should be large enough to cover the IOV VF memory space needs. For example, assuming the memory page size is 4K and 8 VFs are enabled, then 256 KBytes of RAM should be requested (16 K for the CSR BAR, 16 K for the MSI-X BAR by 8 functions).
2. Before enabling IOV, zero the flash BAR and program the IOV BARs to use the old flash BAR. The VFs CSR BAR may use the first half of the original flash memory and the MSI-X BAR may use the second half.

## 7.8.3 Packet Switching (VMDq) Model

### 7.8.3.1 VMDq Assumptions

The following assumption are made:

1. The required bandwidth for the VM to VM loopback traffic is low. For example, the PCIe BW is not congested by the combination of the VM to VM and the regular incoming traffic. This case is handled but not optimized for. Unless specified otherwise, Tx and Rx packets should not be dropped or lost due to congestion caused by loopback traffic.
2. Most of the offloads provided on Rx traffic are not provided for the VM to VM loopback traffic.

3. If the buffer allocated for the VM to VM loopback traffic is full, it is OK to back pressure the transmit traffic of the same traffic class. This mean that the outgoing traffic might be blocked if the loopback traffic is congested.
4. The decision on VM to VM loopback traffic is done only according to the Ethernet DA address and the VLAN tag. There is no filtering according to other parameters (IP, L4, etc.). This switch have no learning capabilities.
5. The forwarding decisions are based on the receive filtering programming.
6. When the link is down, the Tx flow is stopped, and thus the local switching traffic is stopped also.

### 7.8.3.2 VM/VF Selection

The VM/VF selection is done by MAC address and VLAN tag. Broadcast and Multicast packets are forwarded according to the individual setting of each VM and might be replicated to multiple VMs.

#### 7.8.3.2.1 Filtering Capabilities

The following capabilities exists in to decide what is the final destination of each packet in addition to the regular L2 filtering capabilities:

- 32 MAC addresses filters (*RAH/RAL* registers) for both unicast and multicast filtering. These are shared with L2 filtering. For example, the same MAC addresses are used to determine if a packet is received by the switch and to determine the forwarding destination.
- 32 Shared VLAN filters (*VLVF* registers) - each VM can be made member of each VLAN.
- Multicast exact filtering using the existing remaining *RAH/RAL* registers otherwise an imperfect multicast table is shared between VMs.
- 256 hash filtering of multicast addresses shared between the VMs (*MTA* table).
- Promiscuous unicast, multicast & enable broadcast per VM.
- Promiscuous VLAN per VM.

**Note:** Packets for which no queueing decision was done and still accepted by the L2 filtering, is directed to the queue pool of the default VM/VF or dropped.

### 7.8.3.3 L2 Filtering

L2 filtering is the 1st stage of 3 stages that determine the destination of a received packet. The 3 stages are defined in [Section 7.1.1](#).

All received packets pass the same filtering as in the non virtualized case; regular VLAN filtering using the global VLAN table (*VFTA*) of the PF and filtering according to the *RAH/RAL* registers and according to the various promiscuous bits.

**Note:** Every VLAN tag set in the *VLVF* registers should be asserted also in the *VFTA* table.

**Note:** The *RCTL.UPE* bit (Promiscuous unicast) is not available per VM and might be modified by the IOVM or VMM and might be modified only by the PF driver. This bit should be set if *VMOLR.UPE* is set for one of the VF drivers.

### 7.8.3.4 VMDq Receive Packets Switching

Receive packet switching is the 2nd stage of 3 stages that determine the destination of a received packet. The 3 stages are defined in [Section 7.1.1](#).

As far as switching is concerned, it doesn't matter whether our virtual environment operates in IOV mode or in Next Generation VMDq mode. In this stage the VM/VF is identified by the "pool list" as described in [Section 7.8.3.4.1](#) and [Section 7.8.3.4.2](#).

When working in a virtualized environment, the 3rd stage of definition of a queue is not relevant.

When working in replication mode, broadcast and multicast packets can be forwarded to more than one VM, and can be replicated to more than one receive queue. Replication is enabled by the *Rpl\_En* bit in the *VT\_CTL* register.

In virtualization mode, the pool list is a list of one or more VMs to which the packet should be forwarded. The pool list is used in choosing the target queue list except for cases in which high priority filters take precedence. There is a difference in the way the pool list is generated when replication mode is enabled or disabled.

#### 7.8.3.4.1 VMDq Replication Mode Enabled

When replication mode is enabled (*VT\_CTL.Rpl\_En* = 1), each broadcast/multicast packet can go to more than one pool. Finding the pool list should be done according to the following steps:

1. Exact unicast or multicast match - If there is a match in one of the exact filters (*RAL/RAH*), for unicast or multicast packets, take the *RAH.POOLSEL[7:0]* field as a candidate for the pool list.
2. VFRE — If any bit in the VFRE register is cleared, clear the respective bit in the pool list.
3. Broadcast - If the packet is a broadcast packet, add pools for which their *VMOLR.BAM* bit (Broadcast Accept Mode) is set.
4. Unicast hash - If the packet is a unicast packet, and the prior steps yielded no pools, check it against the Unicast Table Array hash (*UTA*). If there is a match, add pools for which their *VMOLR.ROPE* bit (Receive Overflow packet enable) is set.
5. Multicast hash - If the packet is a multicast packet and the prior steps yielded no pools, check it against the multicast Table Array hash (*MTA*). If there is a match, add pools for which their *VMOLR.ROMPE* bit (Receive Multicast packet enable) is set.
6. Multicast Promiscuous - If the packet is a multicast packet, take the candidate list from prior steps and add pools for which their *VMOLR.MPE* bit (Multicast Promiscuous Enable) is set.
7. Unicast Promiscuous - If the packet is a unicast packet, take the candidate list from prior steps and add pools for which their *VMOLR.UPE* bit (Unicast Promiscuous Enable) is set.
8. Ignore MAC (VLAN only filtering) - If *VT\_CTL.IGMAC* bit is set, then the previous steps are ignored and a full pool list is assumed for the next step.
9. VLAN groups - This step is relevant only if the *RCTL.VFE* bit is set, otherwise it is skipped. Packets should be sent only to VMs that belong to the packet's VLAN group. Thus the following rules are applied only to entries set in the pool list by previous steps:
  - a. Tagged packets: enable only pools in the packet's VLAN group as defined by the VLAN filters - *VLVF[n].VLAN\_id* and their pool list - *VLVF[n].POOLSEL[7:0]* or pools for which the *VMOLR.VPE* (VLAN Promiscuous Enable) is set.
  - b. Untagged packets: enable only pools with their *VMOLR.AUPE* bit set
  - c. If there is no match, the pool list should be empty.
  - d. If the *VLVF.LVLAN* is set, then the packet is not received from the network even if one of the previous conditions is met and the packet is dropped.

**Note:** In a VLAN network, untagged packets are not expected. Such packets received by the switch should be dropped, unless their destination is a virtual port set to receive these packets. The setting is done through the *VMOLR.AUPE* bit. It is assumed that VMs for which this bit is set are members of a default VLAN and thus only MAC queuing is done on these packets.

10. VFRE — If any bit in the VFRE register is cleared, clear the respective bit in the pool list.
11. Default Pool - If the pool list is empty at this stage and the *VT\_CTL.Dis\_Def\_Pool* bit is not set, then set the default pool bit in the target pool list (from *VT\_CTL.Def\_PL*).
12. Ethertype filters - If the one of the Ethertype filters (*ETQF*) matches the packet and queuing action is requested, the VM list is set only to the pool pointed by the filter.
13. Filter Local Packets: If the *VT\_CTL.FLP* bit is set, and the packet SA matches one of the *RAH/RAL*, remove from the VM list all the VMs set in the *RAH.POOLSEL[7:0]*.
14. VFRE — If any bit in the VFRE register is cleared, clear the respective bit in the pool list.
15. Length Limit: If the packet is longer than a legal Ethernet packet, remove from the pool list all the pools for which the *VMOLR.LPE* bit is not set or for which the packet length is larger than the value in the *VMOLR.RLPML* field.
16. Mirroring - If the pool list is not empty, for each of the 4 mirroring rules add the destination (mirroring) pool (*VMRCTL.MP*) to the pool list according to the following rules:
  - a. Pool mirroring - if *VMRCTL.VPME* is set and one of the bits in the pool list matches one of the bits in the *VMRVM* register.
  - b. VLAN port mirroring - if *VMRCTL.VLME* is set and the index of the VLAN of the packet in the *VLVF* table matches one of the bits in the *VMRVLAN* register.
  - c. Uplink port mirroring - if *VMRCTL.UPME* is set and the packet came from the LAN.
  - d. VFRE — If any bit in the VFRE register is cleared, clear the respective bit in the pool list.
17. Length Limit: If the packet is longer than a legal Ethernet packet, remove from the pool list all the pools for which the *VMOLR.LPE* bit is not set or for which the packet length is larger than the value in the *VMOLR.RLPML* field.

#### 7.8.3.4.2 VMDq Replication Mode Disabled

When replication mode is disabled (*VT\_CTL.Rpl\_En* = 0), the software should take care of multicast and broadcast packets and check which of the VMs should get them. In this mode the pool list always contains one pool only according to the following steps:

1. Exact unicast or multicast match - If the packet DA matches one of the exact filters (*RAL/RAH*), take the *RAH.POOLSEL[7:0]* field as a candidate for the pool list.
2. VFRE — If any bit in the VFRE register is cleared, clear the respective bit in the pool list
3. Unicast hash - If the packet is a unicast packet, and the prior steps yielded no pools, check it against the Unicast Table Array hash (*UTA*). If there is a match, add the pool for which the *VMOLR.ROPE* bit (Receive Overflow packet enable) is set. (See software limitation no 3. below).
4. Ignore MAC (VLAN only filtering) - If *VT\_CTL.IGMAC* bit is set, then the previous step is ignored and a full pool list is assumed for the next step.
5. VLAN groups - This step is relevant only if the *RCTL.VFE* bit is set, otherwise it is skipped. Packets should be sent only to VMs that belong to the packet's VLAN group. Thus the following rules are applied only to entries set in the pool list by previous steps:
  - a. Tagged packets: enable only pools in the packet's VLAN group as defined by the VLAN filters - *VLVF[n].VLAN\_id* and their pool list - *VLVF[n].POOLSEL[7:0]* or pools for which the *VMOLR.VPE* (VLAN Promiscuous Enable) is set.
  - b. Untagged packets: enable only pools with their *VMOLR.AUPE* bit set
  - c. If there is no match, the pool list should be empty.

- d. If the *VLVF.LVLAN* is set, then the packet is not received from the network even if one of the previous conditions is met and the packet is dropped.
6. VFRE — If any bit in the *VFRE* register is cleared, clear the respective bit in the pool list
7. Default pool - If the packet is a unicast packet or *VT\_CTL.IGMAC* is set and no pool was chosen and the *VT\_CTL.Dis\_Def\_Pool* bit is not set, then set the default pool bit in the pool list (from *VT\_CTL.Def\_PL*).
8. Broadcast or Multicast - If the packet is a Multicast or Broadcast packet and *VT\_CTL.IGMAC* is not set and no pool was chosen, set the default pool bit in the pool list (from *VT\_CTL.Def\_PL*).
9. Ethertype filters - If the one of the Ethertype filters (*ETQF*) matches the packet and queuing action is requested, the VM list is set only to the pool pointed by the filter.
10. Filter Local Packets: If the *VT\_CTL.FLP* bit is set, and the packet SA matches one of the RAH/RAL, remove from the VM list the VM set in the *RAH.POOLSEL[7:0]*.
11. Length Limit: If the packet is longer than a legal Ethernet packet, remove from the pool list all the pools for which the *VMOLR.LPE* bit is not set or for which the packet length is larger than the value in the *VMOLR.RLPML* field.
12. VFRE — If any bit in the *VFRE* register is cleared, clear the respective bit in the pool list.

The following limitations applies when replication is disabled:

1. It is the software responsibility to not set more than one bit in the bitmaps of the exact filters. Note that multiple bits might be set in an RAH register as long as it is guaranteed that the packet is sent to only one queue by other means (VLAN)
2. The software must not set per-VM promiscuous bits (unicast, multicast or broadcast) in the *VMOLR* register.
3. The software must not set the *ROPE* bit in more than one *VMOLR* register.
4. If *VT\_CTL.IGMAC* bit is set, the software must not set the *VMOLR.AUPE* in more than one *VMOLR* register and must not set more than one bit in each of the *VLVF.POOLSEL* bitmaps and must not set the *VMOLR.VPE* in any pool.
5. The software must not activate mirroring.

### 7.8.3.5 TX Packets Switching

TX switching is used only in a virtualized environment to serve VM to VM traffic. Packets that are destined to one or more local VMs, are loop backed to the RX path through a separate packet buffer. Enabling TX switching is done by setting the *TXSWC.Loopback\_en* bit.

TX switching is very similar to RX switching in a virtualized environment, with the following exceptions and rules:

- The high priority filters (EType/SYN/5-Tuple) are not applied to the Tx traffic.
- If a target pool is not found, the default pool is not used, and the packet will only go to the external LAN.
- A unicast packet that is destined to one of the VMs by an exact filter is not sent to the LAN unless the *RAH.TRMCAST* (Treat as Multicast) bit is set.
- Broadcast and multicast packets are always sent to the external LAN too, unless member of a local VLAN.
- If an outgoing packets VLAN matches a *VLVF* entry with the *LVLAN* bit set, this packet is not sent to the external LAN. This rule overrides previous rules.
- A packet might not be sent back to the originating VM (even if the destination address is equal to the source address). However, In order to off-load a software switch allowing Multiple VMs sharing the same pool or for VF loopback diagnostics, the I350 provides the capability to loopback packets

inside a pool. In the normal case, a packet whose source and destination are the same is dropped (usually occurs with multicast packets). If the Local Loopback bit mode (*LLE*) in *TXSWC* is set for this pool, packets originating from a given pool can be sent to the same pool.

The detailed flow for pool selection is described below.

**Figure 7-24 Tx Filtering**

**Figure 7-25 Tx Filtering**

The following rules apply to loopback traffic:

- Loopback is disabled when the network link is disconnected. It is expected (but not required) that system software (including virtual machines) does not post packets for transmission when the link is disconnected.
- Loopback is disabled when the *Receive Enable (RXEN)* bit is cleared.
- Loopback packets are identified by the *LB* bit in the receive descriptor.

**Note:** NLB is a mode of Microsoft where a unicast address behaves as a multicast address in that it is used by multiple machines. In order to support this mode, it should be possible to forward part of the unicast MAC addresses to the network the same way we do for multicast addresses. In order to support this mode, the *RAH.TRMCSST* bit is added. This bit is used to decide if packets are forwarded to the network even if they are forwarded to local addresses.

### 7.8.3.5.1 Replication Mode Enabled

When replication mode is enabled, the pool list for Tx packets is determined according to the following steps:

1. Exact unicast or multicast match - If there is a match in one of the exact filters (*RAL/RAH*), for unicast or multicast packets, take the *RAH.PLSEL* field as a candidate for the pool list.
2. VFRE — If any bit in the *VFRE* register is cleared, clear the respective bit in the pool list.
3. Broadcast - If the packet is a broadcast packet, add pools for which their *VMOLR.BAM* bit (Broadcast Accept Mode) is set.

4. Unicast hash - If the packet is a unicast packet, and the prior steps yielded no pools, check it against the Unicast Table Array hash (*UTA*). If there is a match, add pools for which their *VMOLR.ROPE* bit (Receive Overflow packet enable) is set.
5. Multicast hash - If the packet is a multicast packet and the prior steps yielded no pools, check it against the Multicast Table Array hash (*MTA*). If there is a match, add pools for which their *VMOLR.ROMPE* bit (Receive Multicast packet enable) is set.
6. Multicast Promiscuous - If the packet is a multicast packet, take the candidate list from prior steps and add pools for which their *VMOLR.MPE* bit (Multicast Promiscuous Enable) is set.
7. Unicast Promiscuous - If the packet is a unicast packet, take the candidate list from prior steps and add pools for which their *VMOLR.UPE* bit (Unicast Promiscuous Enable) is set.
8. Ignore MAC (VLAN only filtering) - If *VT\_CTL.IGMAC* bit is set, then the previous step is ignored and a full pool list is assumed for the next step.
9. VLAN groups - This step is relevant only if the *RCTL.VFE* bit is set, otherwise it is skipped. Packets should be sent only to VMs that belong to the packet's VLAN group. Thus the following rules are applied only to entries set in the pool list by previous steps:
  - a. Tagged packets: enable only pools in the packet's VLAN group as defined by the VLAN filters - *VLVF[n].VLAN\_id* and their pool list - *VLVF[n].POOLSEL[7:0]* or pools for which the *VMOLR.VPE* (VLAN Promiscuous Enable) is set.
  - b. Untagged packets: enable only pools with their *VMOLR.AUPE* bit set
  - c. If there is no match, the pool list should be empty.
10. Forwarding to the Network:
  - a. All broadcast and multicast packets are sent to the network also.
  - b. Unicast packets: If *VT\_CTL.IGMAC* bit is cleared and after step 2. the pool list is empty or the matching *RAH.TRMCS* bit is set, the packet is sent to the network also. If *VT\_CTL.IGMAC* bit is set and the pool list at this stage is empty the packet is sent to the network also.
  - c. If the *VLVF.LVLAN* is set, then the packet is not sent to the network even if one of the previous conditions is met.
11. VFRE — If any bit in the *VFRE* register is cleared, clear the respective bit in the pool list.
12. Length Limit: If the packet is longer than a legal Ethernet packet, remove from the pool list all the pools for which the *VMOLR.LPE* bit is not set or for which the packet length is larger than the value in the *VMOLR.RLPML* field.
13. Filter source port - The pool from which the packet was sent is removed from the pool list unless the *TXSWC.LLE* bit is set.
14. Ingress Mirroring - If the pool list is not empty, each of the 4 mirroring rules adds its destination pool (*VMRCTL.MP*) to the pool list if the following applies:
  - a. Pool mirroring - *VMRCTL.VPME* is set and one of the bits in the pool list matches one of the bits in the *VMRVM* register.
  - b. VLAN port mirroring - *VMRCTL.VLME* is set and the index of the VLAN of the packet in the *VLVF* table matches one of the bits in the *VMVLAN* register.
  - c. VFRE — If any bit in the *VFRE* register is cleared, clear the respective bit in the pool list.
15. Egress mirroring - For each of the 4 mirroring rules, if *VMRCTL.DPME* is set and the packet is sent to the network add the destination pool (*VMRCTL.MP*) to the pool list.
16. Length Limit: If the packet is longer than a legal Ethernet packet, remove from the pool list all the pools for which the *VMOLR.LPE* bit is not set or for which the packet length is larger than the value in the *VMOLR.RLPML* field.

### 7.8.3.5.2 Replication Mode Disabled

When replication mode is disabled, the software should take care of multicast and broadcast packets and check which of the VMs should get them. In this mode the pool list for Tx packets always contains at the most one pool according to the following steps:

1. Exact unicast or multicast match - If the packet DA matches one of the exact filters (RAL/RAH), take the *RAH.PLSEL* field as a candidate for the pool list.
2. VFRE — If any bit in the VFRE register is cleared, clear the respective bit in the pool list.
3. Unicast hash - If the packet is a unicast packet, and the prior steps yielded no VMs, check it against the Unicast hash table (UTA). If there is a match, add pools for which their *VMOLR.ROPE* bit (Receive Overflow packet enable) is set.
4. Ignore MAC (VLAN only filtering) - If *VT\_CTL.IGMAC* bit is set, then the previous steps are ignored and a full pool list is assumed for the next step.
5. VLAN groups - This step is relevant only if the *RCTL.VFE* bit is set, otherwise it is skipped. Packets should be sent only to VMs that belong to the packet's VLAN group. Thus the following rules are applied only to entries set in the pool list by previous steps:
  - a. Tagged packets: enable only pools in the packet's VLAN group as defined by the VLAN filters - *VLVF[n].VLAN\_id* and their pool list - *VLVF[n].POOLSEL[7:0]* or pools for which the *VMOLR.VPE* (VLAN Promiscuous Enable) is set.
  - b. Untagged packets: enable only pools with their *VMOLR.AUPE* bit set.
  - c. If there is no match, the pool list should be empty.
6. Forwarding to the Network:
  - a. All broadcast and multicast packets are sent to the network also.
  - b. Unicast packets: If *VT\_CTL.IGMAC* bit is cleared and after step 2. the pool list is empty or the matching *RAH.TRMCSST* bit is set, the packet is sent to the network also. If *VT\_CTL.IGMAC* bit is set and the pool list at this stage is empty the packet is sent to the network also.
  - c. If the *VLVF.LVLAN* is set, then the packet is not sent to the network even if one of the previous conditions is met.
7. Broadcast or Multicast - If the packet is a Multicast or Broadcast packet and *VT\_CTL.IGMAC* is not set and no pool was chosen, set the default pool bit in the pool list (from *VT\_CTL.Def\_PL*).
8. Length Limit: If the packet is longer than a legal Ethernet packet, remove from the pool list all the pools for which the *VMOLR.LPE* bit is not set or for which the packet length is larger than the value in the *VMOLR.RLPML* field.
9. VFRE — If any bit in the VFRE register is cleared, clear the respective bit in the pool list.
10. Filter source port - The pool from which the packet was sent is removed from the pool list unless the *TXSWC.LLE* bit is set.

The limitations listed in [Section 7.8.3.4.2](#) applies for Tx traffic also.

### 7.8.3.6 Mirroring Support

The I350 supports 4 mirroring rules. Each rule can be of one of 5 types. Mirroring is supported only to virtual ports and not to the uplink (i.e. a mirrored packet can not be sent back to the Network).

Mirroring should be activated only when one of the VMDq queueing modes is used.

The following types of rules are supported:

1. Virtual port mirroring - reflects all the packets sent to a set of given VMs.
2. Uplink port mirroring - reflects all the traffic received from the network.
3. Downlink port mirroring - reflects all the traffic transmitted to the network.

4. Receive mirroring - reflects all the traffic received by any of the VMs. Either from the network or from local VMs. This is supported by enabling mirroring of all VMs.
5. VLAN mirroring - reflects all the traffic received in a set of given VLANs. Either from the network or from local VMs.

All the modes can be accumulated into a single rule.

These mirroring rules are controlled by a set of rule control registers:

- *VMRCTL* - controls the rules to be applied and the destination port.
- *VMRVLAN* - controls the VLAN ports as listed in the *VLVF* table taking part in the VLAN mirror rule.
- *VMRVM* - controls the VMs ports taking part of the Virtual port mirror rule.

Mirroring is supported only when replication is enabled. The exact flow of mirroring is described in step 15. in [Section 7.8.3.4.1](#).

## 7.8.3.7 Offloads

### 7.8.3.7.1 Split Header Offload

In case of packets directed to one VM only, the split header size is determined by the specific VM setting. However, the I350 can not apply different split header size to different replication of the same packet. The following sections describes the rules used to decide which split header size to apply in case of replicated packets.

#### 7.8.3.7.1.1 Replication by Exact MAC Address

As mentioned above, the same MAC address can be assigned to more than one VM. This is used for the following cases:

- Multicast address - In this case, the different VMs might be part of the same VLAN. The header size applied to packets matching this address is defined in the *RPLPSRTYPE* register.
- Unicast - Same MAC different VLAN - In this case, each VM should belong to different VLAN(s). The applied offloads is according to the pool selected by the MAC/VLAN pair.

#### 7.8.3.7.1.2 Replication by Promiscuous Modes

A packet might be replicated to multiple VMs because part of the VMs are set to receive all multicast or broadcast packets or because of a packet matching one of the hash tables (*UTA* or *MTA*). The header size applied to packet is defined in the *RPLPSRTYPE* register.

In case of unicast packet, the header size is applied according the first of the pools selected to receive the packet.

#### 7.8.3.7.1.3 Replication by Mirroring

- Header size of mirrored packets are determined according to the original pool.

### 7.8.3.7.2 Local VM to VM Traffic Offload

Most of the offloads available for regular incoming traffic are not available in case of loop back traffic. The driver might handle the lack of the offloads as follows:

1. **Checksum** - The transmit path always adds a checksum - either by the driver or by the I350, but this checksum is not validated by the receive path. As this packet wasn't sent over the network, the receive side might assume the TCP and IP checksums are valid.
2. **Packet types identification** - The L3 packet type identification is provided only if at least one of the following offloads is requested for the transmitted packet: IP checksum or L4 checksum. The L4 packet type identification is provided only if L4 checksum is requested for the transmitted packet. A packet might be identified as IPv4 with extensions only if IP checksum was requested on this packet. L5 Packet type identification is not valid for loop back packets.
3. **Header split & replication** - Available only for part of the local packets. It is available only if the header split boundary is at the L4 level (TCP/UDP), in cases where the Tx side provided a valid L4 packet type (in packets for which L4 checksum is requested). In all other cases the SPH is set to zero.
4. **Error bits** - The error bits are also fixed to zero - although most of the errors are not relevant for loop back packets.
5. **Special queueing filters** such as 5-tuple filter or ether-type filter are not applied to the local traffic. A driver using such filters should check if a packet belongs to a special queue and redirect it accordingly.

### 7.8.3.7.3 Small Packets Padding

In Virtualized systems, the driver receiving the packet in the VM might not be aware of all the hardware offloads applied to the packet. Thus, in case of stripping actions by the hardware (VLAN strip), it might receive packets which are smaller than a legal packet. The I350 provides an option to pad small packets in such cases so that all packets have a legal size. This option can be enabled only if the CRC is stripped. In these cases, all packets are padded to 60 bytes (legal packet - 4 bytes CRC). The padding is done with zero data. This function is enabled via the *RCTL.PSP* bit.

## 7.8.3.8 Security Features

The I350 allows some security checks on the inbound and outbound traffic of the switch.

### 7.8.3.8.1 Inbound Security

Each incoming packet (either from the LAN or from a local VM) is filtered according to the VLAN tag so that packets from one VLAN can not be received by VMs that are not members of that VLAN.

When the VLAN is inserted by the switch, it is preferable to hide the received VLAN from the guest OS, as exposing it can create a security hole. The I350 allows removal of the VLAN tag from received packet, so that the receiving VM is not aware of the VLAN network it belongs to.

This mode is controlled using the *hide VLAN* bit in the *DVMOLR* register. If this bit is set, the VLAN is always stripped, a value of zero is written in the *RDESC.VLAN tag* and in the *RDESC.STATUS.VP* fields of the received descriptor.

### 7.8.3.8.2 Outbound Security

#### 7.8.3.8.2.1 Anti-Spoofing

The source MAC address of each outgoing packet can be compared to the MAC address the sending VM uses for packets reception. A packet with a non matching SA is dropped. Thus preventing spoofing of the MAC address. In this mode, the SA of a transmit packet is compared with the addresses stored in

the *RAH/RAL* registers. If a match is found and the pool from which the packet was sent is enabled in the *RAH.POOLSEL*, the packet can be forwarded, otherwise the packet is dropped and a notification is sent to the VMM via the *ICR.MDDET* bit and *WVBR.WVM* field.

This feature is enabled in the *TXSWC.MACAS* field, and can be enabled per VF.

**Note:** MAC Anti Spoofing is not available for VMs that hides behind them other VMs whose MAC addresses are not part of the *RAH/RAL* MAC address registers. In this case anti-spoofing should be done by the software switching handling these VMs.

If VLAN anti spoofing is set, a check is done to validate that sender is a member of the VLAN set in the packet. In this mode, the VLAN ID of a transmit packet is compared with the VLAN tag stored in the *VLVF* registers. If a match is found and the pool from which the packet was sent is enabled in the *VLVF.POOLSEL*, the packet can be forwarded, otherwise the packet is dropped and a notification is sent to the VMM via the *ICR.MDDET* bit and *WVBR.WVM* field. The *VMOLR.AUPE* bit is used to decide if untagged packets can be forwarded.

This feature is enabled via the *TXWSC.VLANAS* field, and can be enabled per VF.

**Note:** VLAN anti spoofing is not available for pools programmed to receive all VLANs (*VMOLR.VPE* is set).

#### 7.8.3.8.2.2 VLAN Insertion From Register Instead of Descriptor

There are cases, where the VLAN should be inserted by the switch without intervention from the guest operating system. In VMDq mode, where the physical driver is controlled by a trusted central entity, we can assume the software requests inserting the right tag. However, in IOV scenarios, the driver might be malicious, and thus we can not assume it uses the right VLAN tags. In order to overcome this issue, default VLAN tags are defined per VM, and a default behavior is defined. The possible behaviors that can be set in the *VMVIR.vlana* field are:

1. Use descriptor value - to be used in case of a trusted VM that can decide which VLAN to send. This option should be used also in case one VM is member of multiple VLANs.
2. Always insert default VLAN value defined in *VMVIR.Port VLAN ID* field - this mode should be used for non trusted or non VLAN aware VMs. In this case any VLAN insertion command from the VM is ignored. If a packet is received with a VLAN, the packet should be dropped.
3. Never insert VLAN - This mode should be used in non VLAN network. In this case any VLAN insertion command from the VM is ignored. If a packet is received with a VLAN, the packet should be dropped.

**Note:** The VLAN insertion settings should be done before any of the queues of the VM are enabled.

#### 7.8.3.8.2.3 Egress VLAN Filtering

Part of the VLANs used by VMM vendors are VLAN local to the virtualized server. Packets sent with a private VLAN should not be forwarded to the external network. Local VLANs are indicated by setting the *LVLAN* bit in the adequate *VLVF* entry.

**Note:** A packet with a local VLAN tag whose destination is not in the server is dropped. This means that a local VLAN should be confined to one physical port and can not have member VMs connected to different ports even in the same NIC.

#### 7.8.3.8.3 Interrupt on Misbehavior of VM (Malicious Driver Detection)

The hardware can be programmed to take some action as a result of some misbehavior of a VM. For example upon detection of a packet with a wrong source MAC address, the hardware might block the packet. These actions might hint to the fact that some VM is malicious and the VMM should remedy the situation. In order to inform the VMM of this fact, an interrupt bit exists in the ICR register (*ICR.MDDET* bit) to indicate the occurrence of such behavior. The LVMMC register contains information on which queue (*LVMMC.Last\_Q*) and port (*LVMMC.Mal\_PF*) the malicious behavior was detected. The LVMMC register is clear by read.

Malicious driver behavior detection is enabled by setting the *DTXCTL.MDP\_EN* bit to 1. On detection of a malicious driver event the I350 stops activity of the offending queue, asserts relevant bit in the *MDFB.Block Queue* field and generates an interrupt by asserting the *ICR.MDDET* bit. Cause of Malicious driver activation is reported in the LVMMC register. To re-activate offending queue, driver should either reset the offending VF or re-enable the relevant VFTE bit.

### 7.8.3.8.3.1 Transmit Descriptor Validity Checks

The table below describes the checks are done by the I350 to define if a transmit packet descriptor is valid. All the checks are done on the descriptors. The checks on the packet header are described in the previous sections.

**Table 7-68 Malicious Driver - TX descriptor checks**

| Check type                                  | Description                                                                                                                      | Action                               |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Mac Header size                             | Checks that the MAC header size in the context descriptor is at least 14 (or 18 in case of offloaded packet and double VLAN).    | Drop Packet and stop offending queue |
| IPv4 Header                                 | If a checksum or TSO offload is required, checks that the IPv4 header size in the context descriptor is at least 20.             | Drop Packet and stop offending queue |
| IPv6 Header                                 | If a TSO offload is required, checks that the IPv6 header size in the context descriptor is at least 40.                         | Drop Packet and stop offending queue |
| Wrong MAC_IP                                | Check that the MAC+ IP header size is not bigger than the packet size.                                                           | Drop Packet and stop offending queue |
| TCP header size                             | If a TCP TSO offload is required, checks that the TCP header size in the context descriptor is at least 20.                      | Drop Packet and stop offending queue |
| UDP header size                             | If a UDP TSO offload is required, checks that the TCP header size in the context descriptor is at least 8.                       | Drop Packet and stop offending queue |
| SCTP data size                              | If a SCTP checksum offload is required, checks that the SCTP L4 packet size (including header and data) is at least 12.          | Drop Packet and stop offending queue |
| Packet too big                              | In case of a single send, check that the packet is not larger than the value set in the <i>DTXMXPKTSZ</i> register.              | Drop Packet and stop offending queue |
| Packet too small                            | Check that the total length of the packet transmitted, not including FCS is at least 13 bytes (or 17 if double VLAN is enabled). | Silently drop packet.                |
| Illegal offload request.                    | Check that TSO is no requested for SCTP or that a checksum offload is not requested for IPv6 packets.                            | Drop Packet and stop offending queue |
| SCTP alignment                              | If an SCTP CRC offload is requested, check that the data size is 4 byte aligned.                                                 | Drop Packet and stop offending queue |
| Zero MSS                                    | Check that the MSS size is larger than zero.                                                                                     | Drop Packet and stop offending queue |
| Context in middle of packet                 | Check that a context descriptor is not sent in the middle of a packet.                                                           | Drop Packet and stop offending queue |
| Number of large send header buffers         | Check that the Large send header is contained in at most 4 buffers.                                                              | Drop Packet and stop offending queue |
| Buffers size and length match - Single Send | For single send, check that the total of all buffers size and the packet length match.                                           | Drop Packet and stop offending queue |

**Table 7-68 Malicious Driver - TX descriptor checks**

| Check type                                 | Description                                                                                                         | Action                               |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Buffers size and length match - Large Send | For LSO, check that the total of all buffers size and the packet length match.                                      | Drop Packet and stop offending queue |
| UDP data size                              | If a UDP checksum offload is required, checks that the UDP L4 packet size in the context descriptor is at least 8.  | Drop Packet and stop offending queue |
| TCP data size                              | If a TCP checksum offload is required, checks that the TCP L4 packet size in the context descriptor is at least 20. | Drop Packet and stop offending queue |
| Descriptor Type                            | Check that only descriptor types 2 (context) or 3 (advanced data descriptor) are used.                              | Drop Packet and stop offending queue |
| Null packet check                          | Check that a Null packet has the EOP bit set.                                                                       | Drop Packet and stop offending queue |
| Packet without EOP                         | Check that a only entire packets are provided by the driver                                                         | Drop Packet and stop offending queue |
| Burst of contexts                          | Check that less than <i>DTXCTL.Cswthres</i> Contiguous context descriptor are sent by the driver.                   | Drop Packet and stop offending queue |

### 7.8.3.8.3.2 Reactive Malicious behavior detection

The table below describes the checks are done by the I350 to detect a malicious behavior, even if the packet seems valid.

**Table 7-69 Reactive malicious checks**

| Check type                 | Description                                                                                                                                    | Action                               |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Malicious VF memory access | A PCIe DMA access initiated by a VF ended with Unsupported Request (UR) or Completer Abort (CA). This check is done for both Tx and Rx queues. | Drop Packet and stop offending queue |
| Invalid Queue parameters   | Check that the queue length is not null before accepting a queue enable.                                                                       | Ignore queue enable.                 |

### 7.8.3.8.4 Storm Control

As there is no separate path for multicast & broadcast packets, too much replicated packets might cause congestions in the data path. In order to avoid such scenarios, broadcast and multicast storm control rate limiters are added. The rate controllers define windows and the maximal allowed number of multicast or broadcast bytes/packets per window. Once the threshold is crossed different types of policies can be applied.

#### 7.8.3.8.4.1 Assumptions

- Only one interval size and interval counter is used for both broadcast & multicast storm control mechanisms.
- The threshold and actions for each mechanism are separate.
- The traffic used to calculate the broadcast & multicast rate is all the traffic with a local destination - either Tx or Rx.
- The storm control does not block traffic to the network.
- The basic unit of traffic counted is 64 bytes of data.

#### 7.8.3.8.4.2 Storm Control Functionality

The time interval over which Broadcast Storm control is performed is controlled by three factors.

- SCBI register
- Port speed.
- The value in *SCCRL.INTERVAL*

The first two factors determine the Unit time interval as described in [Table 7-70](#). The interval is automatically chosen internal to hardware based on port speed. The third factor (*Interval* field) determines how many of such unit intervals are considered for one Storm Control Interval.

**Table 7-70 Storm Control Interval by Speed**

| Port Speed | MIN Time Interval | MAX Time Interval |
|------------|-------------------|-------------------|
| 1 Gb/s     | 100 $\mu$ s       | 100 ms            |
| 100 Mb/s   | 1 ms              | 1 s               |
| 10 Mb/s    | 10 ms             | 10 s              |

The number of 64 bytes chunk of Broadcast or Multicast packets that are allowed in a given interval is determined by setting the *BSCTRH* or *MSCTRH* register respectively.

The I350 supports two modes of reactions to storm event:

1. Block all Multicast or Broadcast packets from the moment the threshold is crossed until the end of the interval. The block is removed at the end of the interval until the threshold is crossed again. This mode is set by asserting *SCCRL.MDICW* (for multicast) or *SCCRL.BDICW* (for broadcasts). This mode is used as a rate limiter.
2. Block all Multicast or Broadcast packets from the moment the threshold is crossed until a full interval without threshold crossing is registered. The block is removed at the end of the interval until the threshold is crossed again. This mode is set by asserting *SCCRL.MDICW* and *SCCRL.MDIPW* (for multicast) or *SCCRL.BDICW* and *SCCRL.BDIPW* (for broadcasts). This mode is used for storm blocking.

The I350 can be programmed to add all packets for which a queue was not found for storm control calculation. For example, packets that passed the 1st stage of L2 filtering but didn't pass the 2nd stage of pooling, or were sent to the default pool, as broadcast packets. This mode is activated by setting the *SCCRL.BIDU* field.

Any change in the storm control state (block or pass of multicast or broadcast packets) is indicated to the software via the *ICR.SCE* interrupt cause. The current state is reflected in the *SCSTS* register.

For diagnostic purpose only, the storm control timer and counters can be read via the *SCTC*, *MSCCNT* & *BSCCNT* registers.

### 7.8.3.9 External Switch Loopback Support

One of the solutions for the switching issue is a mode where an external switch would do the loopback of VM to VM traffic and the NIC is responsible for the replication of multicast packets only. In order to support this mode, the internal loopback mode should be disabled and received packets SA should be compared to the exact MAC addresses to check if the packet originated from a local source, so that the packet is not forwarded to the VM originator. This mode is enabled by the *VT\_CTL.FLP* bit.

### 7.8.3.10 Switch Control

The VMM/IOVM driver has some control of the switch logic. The following registers are available to the VMM/IOVM for this purpose:

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLVF:         | VLAN queuing table: A set of 32 VLAN entries with an associated per VM/VF bit map allowing allocation of each VF or VM to each of the 32 VLAN tags.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| TXSWC:        | DM Tx Switch control register - controls the security setting of the switch such as MAC & VLAN anti spoof filters, local loopback enable and the loopback enable mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| QDE:          | Queue Drop Enable register(s): A register defining whether receive packets destined to a specific queue is dropped if no descriptor are available. This register overrides the individual SRRCTL.DROP_EN bits.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| VT_CTL:       | VT Control register - contains the following fields: <ul style="list-style-type: none"> <li>• Replication enable - allows replication of multicast &amp; broadcast packets - both in incoming &amp; outgoing traffic. If this bit is cleared, Tx multicast &amp; broadcast packets are sent only to the network and Rx multicast &amp; broadcast packets are sent to the default VM.</li> <li>• Default pool - defines where to send packets that passed L2 filtering but didn't pass any of the queueing mechanisms.</li> <li>• Default pool disable- defines whether to drop packets that passed L2 filtering but didn't pass any of the queueing mechanisms.</li> </ul> |
| VMVIR:        | A set of registers used to control VLAN insertion of outgoing packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| VMOLR/DVMOLR: | Defines the offloads and pool selection options for each VF or VM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

In addition the storm control mechanism is programmed as described in [Section 7.8.3.8.4.2](#).

## 7.8.4 Virtualization of the Hardware

This section describes additional features used in both IOV & Next Generation VMDq modes.

### 7.8.4.1 Per Pool Statistics

Part of the statistics are by definition shared and can not be allocated to a specific VM. For example, CRC error count can not be allocated to a specific VM, as the destination of such a packet is not known if the CRC is wrong.

All the non specific statistics is handled by the PF driver in the same way as it is done in non virtualized systems. A VM might require a statistic from the PF driver but might not access it directly.

The conceptual model used to gather statistics in a virtualization context is that each queue pool is considered as a virtual link and the Ethernet link is considered as the uplink of the switch. Thus any packet sent by a VM is counted in the Tx statistics, even if it was forwarded to another VM internally or dropped by the MAC from some reason. In the same way, a replicated packet is counted in each of the VMs receiving it.

The following statistics are provided per VM:

1. Good Packet received count (VFGPRC).
2. Good Packet transmitted count (VFGPTC).
3. Good octets received count (VFGORC).

4. Good octets transmitted count (*VFGOTC*).
5. Rx Packet dropped because of queue descriptors not available (*RQDPC*).
6. Tx Packet dropped because of packet buffer (*TQDPC*).
7. Multicast Packets Received Count (*VFMPRC*).
8. Good Packet received from local VM count (*VFGPRLBC*).
9. Good Packet transmitted to local VM count (*VFGPTLBC*).
10. Good octets received from local VM count (*VFGORLBC*).
11. Good octets transmitted to local VM count (*VFGOTLBC*).

**Note:** All the per VM statistics are read only (RO) and wrap around after reaching their maximal value.

### 7.8.4.1.1 Byte Count Statistics

The component of a packet that are taken into account when calculating the per VF byte statistics (*VFGORC*, *VFGOTC*, *VFGORLBC*, and *VFGOTLBC*) varies according to the following rules:

- For transmit statistics (*VFGOTC*, and *VFGOTLBC*), VLAN tag is part of the byte count only if inserted by the VM. I.e. if the *VMVIR.VLANA* for the VM equals 00 (use descriptor command) and the packet contains a VLAN either in the packet or in the descriptor. CRC is part of the byte count if *DMATXCTRL.Count CRC* is set.
- For receive statistics (*VFGORC*, and *VFGORLBC*), VLAN tag is part of the byte count only if reported to the VM. I.e. if the *DVMOLR.HIDE VLAN* is not set for this VM. CRC is part of the byte count if *DMATXCTRL.Count CRC* is set.

**Note:**

The following tables summarize the size of the packet used for the byte count statistics based on different system settings and packet properties.

**Table 7-71 Tx Packet Size for VFGOTC, and VFGOTLBC**

| VLAN source           | CRC source                   | Count CRC             | Source Packet size <sup>1</sup> | Statistics Packet size |
|-----------------------|------------------------------|-----------------------|---------------------------------|------------------------|
| VMVIR (port based)    | IFCS = 1 (Hardware inserted) | Yes                   | < 60                            | 64                     |
|                       |                              |                       | >60                             | Source packet size +4  |
|                       |                              | No                    | < 60                            | 60                     |
|                       |                              |                       | >60                             | Source packet size     |
|                       | IFCS = 0 (Software inserted) | Illegal configuration |                                 |                        |
| VLE (From descriptor) | IFCS = 1 (Hardware inserted) | Yes                   | < 56                            | 64                     |
|                       |                              |                       | >56                             | Source packet size +8  |
|                       |                              | No                    | < 56                            | 60                     |
|                       |                              |                       | >56                             | Source packet size + 4 |
|                       | IFCS = 0 (Software inserted) | Illegal configuration |                                 |                        |

**Table 7-71 Tx Packet Size for VFGOTC, and VFGOTLBC (Continued)**

| VLAN source | CRC source                   | Count CRC | Source Packet size <sup>1</sup> | Statistics Packet size |
|-------------|------------------------------|-----------|---------------------------------|------------------------|
| In packet   | IFCS = 1 (Hardware inserted) | Yes       | < 60                            | 64                     |
|             |                              |           | > 60                            | Source packet size +4  |
|             |                              | No        | < 60                            | 60                     |
|             |                              |           | > 60                            | Source packet size     |
|             | IFCS = 0 (Software inserted) | Yes       | < 64                            | 64                     |
|             |                              |           | > 64                            | Source packet size     |
|             |                              | No        | < 64                            | 60                     |
|             |                              |           | > 64                            | Source Packet size - 4 |

1. The source packet size defines the packet size as sent by the software.

**Table 7-72 Rx packet size for VFGORC, and VFGORLBC**

| VLAN source                                   | VLAN in Packet? | Count CRC | Statistics Packet size            |
|-----------------------------------------------|-----------------|-----------|-----------------------------------|
| Hide VLAN (port based)                        | Yes             | Yes       | Source packet size <sup>1-4</sup> |
|                                               |                 | No        | Source packet size-8              |
|                                               | No              | Yes       | Source packet size                |
|                                               |                 | No        | Source Packet size - 4            |
| Do not hide VLAN (In descriptor or in packet) | Yes             | Yes       | Source packet size                |
|                                               |                 | No        | Source packet size-4              |
|                                               | No              | Yes       | Source packet size                |
|                                               |                 | No        | Source Packet size - 4            |

1. The source packet size defines the packet size as sent by the network.

## 7.9 Time SYNC (IEEE1588 and IEEE 802.1AS)

### 7.9.1 Overview

IEEE 1588 addresses the clock synchronization requirements of measurement and control systems. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources. The protocol is spatially localized and allows simple systems to be installed and operated without requiring the administrative attention of users.

The IEEE802.1AS standard specifies the protocol used to ensure that synchronization requirements are met for time sensitive applications, such as audio and video, across Bridged and Virtual Bridged Local Area Networks consisting of LAN media where the transmission delays are fixed and symmetrical; for example, IEEE 802.3 full duplex links. This includes the maintenance of synchronized time during normal operation and following addition, removal, or failure of network components and network reconfiguration. It specifies the use of IEEE 1588 specifications where applicable.

Activation of the I350 Time Sync mechanism is possible in full duplex mode only. No limitations on wire speed exist, although wire speed might affect the accuracy. Time Sync protocol is tolerant of dropping packets as well as missing timestamps.

## 7.9.2 Flow and Hardware/Software Responsibilities

The operation of a PTP (Precision Time Protocol) enabled network is divided into two stages, initialization and time synchronization.

At the initialization stage every master enabled node starts by sending Sync packets that include the clock parameters of its clock. Upon reception of a Sync packet a node compares the received clock parameters to its own. If the received clock parameters of a peer are better, the node moves to Slave state and stops sending Sync packets. When in slave state the node continuously compares the incoming packet clock parameters to its currently chosen master. If the new clock parameters are better than the current master selection, it changes master clock source. Eventually the best master clock source is chosen. Every node has a defined Sync packet time-out interval. If no Sync packet is received from its chosen master clock source during the interval it moves back to master state and starts sending Sync packets until a new Best Master Clock (BMC) is chosen.

The time synchronization stage is different for master and slave nodes. If a node is in master state it should periodically send a Sync packet which is time stamped by hardware on the transmit path (as close as possible to the PHY). After the Sync packet a Follow\_up packet is sent which includes the value of the timestamp kept from the Sync packet. In addition the master should timestamp Delay\_Req packets on its RX path and return to the slave that sent it the timestamp value using a Delay\_Response packet. A node in Slave state should timestamp every incoming Sync packet that is received from its selected master, software uses this value for time offset calculation. In addition it should periodically send Delay\_Req packets in order to calculate the path delay from its master. Every sent Delay\_Req packet sent by the slave is time stamped and kept. Using the value received from the master Delay\_Response packet the slave can now calculate the path delay from the master to the slave. The synchronization protocol flow and the offset calculation are described in the following figure.

**Figure 7-26 Sync Flow and Offset Calculation**

The hardware's responsibilities are:

1. Identify the packets that require time stamping.
2. Time stamp the packets on both receive and transmit paths.
3. Store the time stamp value for software.
4. Keep the system time in hardware and give a time adjustment service to the slave software.

5. Maintain auxiliary features related to the system time.

The software's responsibilities are:

1. Best Master Clock protocol execution, which determines which clock is the highest quality clock within the network. Result of protocol sets the node state (master or slave). If node is slave, software also selects the master clock.
2. Generate PTP (Precision Time Protocol) packets, consume PTP packets.
3. Calculate the time offset and adjust the system time using the hardware mechanism.
4. Enable configuration and usage of the auxiliary features.

**Table 7-73 Chronological Order of Events for Sync and Path Delay**

| Action                                                                                                                   | Responsibility | Node Role |
|--------------------------------------------------------------------------------------------------------------------------|----------------|-----------|
| Generate a Sync packet with timestamp notification in descriptor                                                         | Software       | Master    |
| Timestamp the packet and store the value in registers (T1)                                                               | Hardware       | Master    |
| Timestamp incoming Sync packet, store the value in register and store the sourceID and sequenceID in registers (T2)      | Hardware       | Slave     |
| Read the timestamp from register, prepare a Follow_Up packet and send                                                    | Software       | Master    |
| Once Follow_Up packet is received, load T2 from registers and T1 from Follow_up packet                                   | Software       | Slave     |
| Generate a Delay_Req packet with timestamp notification in descriptor                                                    | Software       | Slave     |
| Timestamp the packet and store the value in registers (T3)                                                               | Hardware       | Slave     |
| Timestamp incoming Delay_Req packet, store the value in register and store the sourceID and sequenceID in registers (T4) | Hardware       | Master    |
| Read the timestamp from register and send back to Slave using a Delay_Response packet                                    | Software       | Master    |
| Once Delay_Response packet is received, calculate offset using T1, T2, T3 and T4 values                                  | Software       | Slave     |

### 7.9.2.1 TimeSync Indications in Receive and Transmit Packet Descriptors

Certain indications are transferred between software and hardware regarding PTP packets.

On the transmit path the software should set the *1588* bit in the transmit packet descriptor (MAC field bit 1). To indicate that the transmit packet time stamp should be taken and placed in the *TXSTMPH* and *TXSTMPL* time stamp registers.

On the receive path the hardware transfers three indications to software in the receive descriptor:

1. An indication in *RDESC.Packet Type* that this packet is a PTP packet (no matter if timestamp is sampled or not). This indication is used also by PTP packets required for protocol management.

**Note:** This indication is only relevant for L2 type packets (the PTP packet is identified according to its Ethertype). PTP packets have the *L2Type* bit in the *Packet Type* field set (bit 11) and the *Etype* matches the filter number set by the software to filter PTP packets. UDP type PTP packets don't require such an indication since the port number (319 for event and 320 for all other PTP packets) directs the packets toward the time sync application.

2. A second indication in the *RDESC.STATUS.TS* bit to indicate to the software that time stamp was taken for this packet and placed in the *RXSTMPH* and *RXSTMPL* time stamp registers. Software needs to access the time stamp registers to get the time stamp values.
3. A third indication in the *RDESC.STATUS.TSIP* bit to indicate that a time stamp was taken for this packet and placed at the start of the receive buffer (For further information see [Section 7.1.6](#)).

## 7.9.3 Hardware Time Sync Elements

All time sync hardware elements are reset to their initial values as defined in the registers section upon MAC reset.

### 7.9.3.1 System Time Structure and Mode of Operation

The time sync logic contains the SYSTIM counter to maintain the system time value. This is a 72 bit counter that is built of the SYSTIMR, SYSTIML and SYSTIMH registers. Operation of the counter is enabled by clearing the TSAUXC.Disable systime bit. When in Master state the SYSTIMH, SYSTIML and SYSTIMR registers should be set once by the software according to general system requirements in the following manner:

1. Disable SYSTIM timer operation by setting the TSAUXC.Disable systime bit.
2. Program the SYSTIMH, SYSTIML and SYSTIMR registers.
3. Enable SYSTIM timer operation by clearing the TSAUXC.Disable systime bit.

When in slave state software should update the system time on every sync event as described in [Section 7.9.3.3](#). Setting the system time is done by direct write to the SYSTIMH register as described above, enabling SYSTIM operation by clearing the TSAUXC.Disable systime bit and fine tuning the setting of the SYSTIM register, using the adjustment mechanism described in [Section 7.9.3.3](#).

Read access to the SYSTIMH, SYSTIML and SYSTIMR registers should be executed in the following order:

1. Software reads register SYSTIMR. At this stage the hardware latches the value of SYSTIMH and SYSTIML registers.
2. Software reads register SYSTIML.
3. Software reads register SYSTIMH. The latched SYSTIMH and SYSTIML values (from last read of SYSTIMR register) should be returned by hardware when reading the SYSTIML and SYSTIMH registers.

The SYSTIM timer value in the SYSTIMH, SYSTIML and SYSTIMR registers, is updated periodically each 8 nS clock cycle according to the following formula:

$$\text{New SYSTIM} = \text{Old SYSTIM} + 8 \text{ nS} + / - \text{TIMINCA.Incvalue} * 2^{-32} \text{ nS}$$

Where subtraction or addition of the TIMINCA.Incvalue value is defined according to the TIMINCA.ISGN value (0 - Add, 1 - Subtract). For the TIMINCA register description refer to [section 8.16.12](#).

### 7.9.3.2 Time Stamp Mechanism

The time stamp logic is located on transmit and receive paths at a location as close as possible to the PHY, to reduce delay uncertainties originating from implementation differences. The time stamp logic operation is slightly different on transmit and on receive paths.

When the TSAUXC.Disable systime bit is cleared the transmit logic decides to timestamp a packet if the transmit timestamp is enabled (TSYNCTXCTL.EN = 1) and the time stamp bit in the packet descriptor (TDESD.MAC.1588 = 1) is set. On the transmit side only the time is captured in the TXSTMPL and TXSTMPH registers.

The receive logic parses the received frame and timestamps the receive packet according to the conditions defined in the following fields:

1. TSYNCRXCTL.Type field that defines type of packets to be sampled.
2. TSYNCRXCFG.CTRLT field that defines message type criteria for timestamping V1 type packets when TSYNCRXCTL.Type register field equals 001b.
3. TSYNCRXCFG.MSGT field that defines message type criteria for timestamping V2 type packets when TSYNCRXCTL.Type register field equals 000b or 010b.

When the TSAUXC.Disable systime bit is cleared and above conditions to timestamp a receive packet are met:

1. The timestamp is latched in the RXSTMPL and RXSTMPH registers.
2. The packet's sourceId and sequenceId fields are latched in the RXSATRL and RXSATRH timestamp registers.
3. When the SRRCTL[n].Timestamp bit is set to 1, packets received to the queue will have a timestamp value added to the beginning of the receive buffer (See [Section 7.1.6](#) for additional information).

Three indications are placed in the receive descriptor to support TimeSync operation:

1. RDESC.Packet Type - Value in this field identifies that this is a PTP packet (this indication is only for L2 packets since on the UDP packets the port number directs the packet to the application).
2. RDESC.STATUS.TS - Bit identifies that a time stamp was taken for this packet and latched in RXSTMPL and RXSTMPH registers and the packet's sourceId and sequenceId are latched in the RXSATRL and RXSATRH timestamp registers.
3. RDESC.STATUS.TSIP - Bit identifies that a time stamp was taken for this packet and placed at the start of the receive buffer (For further information see [Section 7.1.6](#)).

For more details please refer to the timestamp registers in [Section 8.16](#). [Figure 7-27](#) defines the exact point where the time value is captured.

On both transmit and receive sides the timestamp values are locked in registers until software reads the TXSTMPH register to unlock Transmit timestamp registers or reads the RXSTMPH register to unlock the receive timestamp registers. As a result, if a new PTP packet that needs to be time stamped arrives before software accesses the timestamp registers, it is not time stamped. In some cases on the receive path a packet that was timestamped might be lost and not reach the host. To avoid a deadlock condition on the time stamp registers the software should keep a watch dog timer to clear locking of the time stamp register. The interval counted by such a timer should be higher than the expected interval between two Sync or Delay\_Req packets depends on the node state (Master or Slave).

**Note:** When TSYNCRXCTL.Type value is 100b, the Receive timestamp registers are not locked after a timestamp event.

**Figure 7-27 Time Stamp Point**

### 7.9.3.3 Time Adjustment Mode of Operation

A Node in a Time Sync network can be in one of two states Master or Slave. When a Time Sync entity is in the Master state it should synchronize other entities to its System Clock. In this case no time adjustments are needed. When the entity is in slave state it should adjust its system clock by using the data arriving in the Follow\_Up and Delay\_Response packets and the time stamp values of the Sync and Delay\_Req packets. When all the values are available the software in the slave entity can calculate its offset in the following manner:

$$\text{Toffset} = [(T2 - T1) - (T3 - T4)] / 2$$

T1 - Timing data in Follow\_Up packet

T2 - Sync Time Stamp

T3 - Delay\_Req Time Stamp

T4 - Timing data in Delay\_Response packet

To increase or decrease the system time value located in the SYSTIMH and SYSTIML registers by the calculated Toffset value, software should write the calculated Toffset value to the TIMADJH and TIMADJL registers in the following order:

1. Write the low portion of the Toffset value to the TIMADJL.TADJL field.
2. Write the high portion of the Toffset value to the TIMADJH.TADJH field with the correct sign in the TIMADJH.Sign bit, to indicate if the Toffset value should be added or subtracted.

A write to the TIMADJH register causes the Toffset value in the TIMADJH and TIMADJL registers to be added or subtracted (depending on the sign bit) to the system time registers (SYSTIMH and SYSTIML), resulting in a new system time that equals previous system time + Toffset.

### 7.9.4 Time Sync Related Auxiliary Elements

The time sync logic implements three types of auxiliary elements using the precise system timer (SYSTIML and SYSTIMH).

## 7.9.4.1 Target Time

The two target time registers TRGTTIML/H0 and TRGTTIML/H1 enable generating a time triggered event to external hardware using one of the SDP pins according to the setup defined in the TSSDP and TSAUXC registers (See [Section 8.16.15](#) and [Section 8.16.27](#)). Each target time register is structured the same as the system time register. If the value of the system time is equal or has passed the value written to one of the target time registers, a change in level or a pulse is generated on the programmed SDP outputs.

### 7.9.4.1.1 SYSTIM Synchronized Level Change Generation on SDP Pins

To generate a level change on one of the SDP pins when System Time (SYSTIM) reaches a pre-defined value, driver should:

1. Select SDPx pin functionality using the appropriate TSSDP.TS\_SDPx\_SEL field (where x is 0, 1, 2 or 3).
  - Program 00b to the TSSDP.TS\_SDPx\_SEL field if level change should occur when SYSTIM equals TRGTTIML/H0.
  - Program 01b to the TSSDP.TS\_SDPx\_SEL field if level change should occur when SYSTIM equals TRGTTIML/H1.
2. Define selected SDPx pin as output, by setting the appropriate SDPx\_IODIR bit (where x is 0,1,2 or 3) in the CTRL or CTRL\_EXT registers.
3. To define that level change is generated on selected SDP pin when SYSTIM is equal or greater than Target Time, program TSAUXC.PLSGx bit (where x is 0 or 1) to 0.
4. Program TRGTTIML/Hx (where x is 0 or 1) to define SYSTIM time where level change should occur.
5. Enable level change or pulse generation by setting the TSAUXC.EN\_TTx bit (where x is 0 or 1).

Each target time register has an enable bit located in the auxiliary control register (TSAUXC.EN\_TTx). When the SDP level has changed (if TSAUXC.PLSGx = 0) on the selected SDP pin, the enable bit is cleared and needs to be set again by software to get another target time event.

### 7.9.4.1.2 SYSTIM Synchronized Pulse Generation on SDP Pins

To generate a pulse on one of the SDP pins when System Time (SYSTIM) reaches a pre-defined value, driver should:

1. Select SDPx pin functionality using the appropriate TSSDP.TS\_SDPx\_SEL field (where x is 0, 1, 2 or 3).
  - Program 00b to the TSSDP.TS\_SDPx\_SEL field if pulse start should occur when SYSTIM equals TRGTTIML/H0.
  - Program 01b to the TSSDP.TS\_SDPx\_SEL field if pulse start should occur when SYSTIM equals TRGTTIML/H1.
2. Define selected SDPx pin as output, by setting the appropriate SDPx\_IODIR bit (where x is 0,1,2 or 3) in the CTRL or CTRL\_EXT registers.
3. Program TSAUXC.PLSGx bit (where x is 0 or 1) to 1 to define that pulse is generated on the selected SDP pin, when Target Time is equal or greater than System Time (SYSTIM).
4. Program the TSAUXC.PLSNegx bit to define if generated pulse is positive or negative.
5. Program TRGTTIML/H0 and TRGTTIML/H1 registers to define pulse start time and pulse duration if pulse generation.

- Note that for pulse generation both the TRGTTIML/H0 and TRGTTIML/H1 Target Time registers are used. Depending on the TSSDP.TS\_SDPx\_SEL field value, one Target Time register is used to define start of pulse and the other is used to define end of pulse.

6. Enable pulse generation by setting both the TSAUXC.EN\_TT0 and TSAUXC.EN\_TT1 bits to 1.

Each target time register has an enable bit located in the auxiliary control register (*TSAUXC.EN\_TTx*). When a pulse is generated on the selected SDP pin, the enable bits are cleared and need to be set again by software to get another target time event.

#### 7.9.4.1.3 Start of Clock Generation on SDP Pins Synchronized to SYSTIM

The I350 supports driving a configurable Clock on the SDP pins. The output clocks generated are synchronized to the global System (SYSTIM) clock. The Target Time registers (TRGTTIML/H0 or TRGTTIML/H1) can be used to trigger toggle of the configurable clock output on a certain system time.

Setting the appropriate TSAUXC.STx (where x is 0 or 1) bit to 1 enables start of clock generation only after Target Time defined in the TRGTTIML/Hx registers is reached (further information can be found in [Section 7.9.4.2](#)).

#### 7.9.4.2 Configurable Frequency Clock

This feature enables to generate up to 2 programmable clocks on the appropriate SDP pins by configuring the SDP pins using the TSSDP register and by programming appropriate values to the Frequency out Control registers (FREQOUT0 and FREQOUT1). The output clocks are synchronized to the global System (SYSTIM) clock and are affected by System time corrections programmed in the TIMINCA register and the TIMADJL/H registers.

When clock generation is enabled, the error correction programmed in the TIMADJL/H registers is compensated from the clock output gradually, at a rate of 1 ns per 8 nS internal clock cycle. The gradual compensation is done to avoid large duty cycle variations in the output clock.

**Note:** Before updating the TIMADJL/H registers, software should verify that the appropriate TSICR.TADJ0/1 register bit was set to indicate that previous one time adjustment has completed.

To generate either Clock 0 or Clock 1 on one of the SDP pins, the following steps should be taken:

1. Program the CHCT field in the relevant FREQOUT0/1 register to define clock half cycle time (See [Section 8.16.20](#) and [Section 8.16.21](#) for additional information).
2. Define SDPx pin functionality to drive clock by programming the appropriate TSSDP.TS\_SDPx\_SEL field and setting the TSSDP.TS\_SDPx\_EN bit to 1 (where x is 0,1,2 or 3).
  - Program 10b to the TSSDP.TS\_SDPx\_SEL field if the FREQOUT0 register is used to define clock frequency.
  - Program 11b to the TSSDP.TS\_SDPx\_SEL field if the FREQOUT1 register is used to define clock frequency.
3. Define selected SDPx pin as output, by setting the appropriate SDPx\_IODIR bit (where x is 0,1,2 or 3) in the CTRL or CTRL\_EXT registers.
4. If clock start needs to be aligned to the system time (SYSTIM), program start of clock toggle in the appropriate Target Time (TRGTTIML0/1 and TRGTTIMH0/1) registers and set the relevant TSAUXC.ST0/1 field to 1.
5. To start clock operation, set the relevant *TSAUXC.EN\_CLK0/1* bit to 1.

Clock out drives initially a logical 0. Clock value toggles each time a System Time duration of *FREQOUT0/1* is reached or passed.

**Note:** Clock output mechanism should be activated only after *SYSTIMH/L* timer is aligned to global system clock and *SYSTIM* timer error correction entered using the *TIMADJL/H* registers is below 64  $\mu$ s.

### 7.9.4.3 Time Stamp Events

Upon a change in the input level of one of the SDP pins that was configured to detect Time stamp events using the TSSDP register, a time stamp of the system time is captured into one of the two auxiliary time stamp registers (*AUXSTMPL/H0* or *AUXSTMPL/H1*).

For example to define timestamping of events in the *AUXSTMPL0* and *AUXSTMPH0* registers, Software should:

1. Set the TSSDP.AUX0\_SDP\_SEL field to select the SDP pin that detects the level change and set the TSSDP.AUX0\_TS\_SDP\_EN bit to 1.
2. Set the TSAUXC.EN\_TS0 bit to 1 to enable timestamping.

### 7.9.5 Time SYNC Interrupts

Time Sync related interrupts can be generated by programming the TSICR, TSIM and TSIS registers. The TSICR register logs the interrupt cause, the TSIM register enables masking specific TSICR bits and the TSIS register enables Software generated Time Sync interrupts. Detailed description of the Time Sync interrupt registers can be found in [Section 8.16.28](#). Occurrence of a Time Sync interrupt sets the ICR.Time\_Sync interrupt bit.

### 7.9.6 PTP Packet Structure

The time sync implementation supports both the 1588 V1 and V2 PTP frame formats. The V1 structure can come only as UDP payload over IPv4 while the V2 can come over L2 with its Ethertype or as a UDP payload over IPv4 or IPv6. The 802.1AS uses only the layer 2 V2 format.

**Table 7-74 V1 and V2 PTP Message Structure**

| Offset in Bytes | V1 Fields          | V2 Fields                       |                     |
|-----------------|--------------------|---------------------------------|---------------------|
| Bits            | 7 6 5 4 3 2 1 0    | 7 6 5 4 3 2 1 0                 |                     |
| 0               | <b>version PTP</b> | transport Specific <sup>1</sup> | <b>message Type</b> |
| 1               |                    | Reserved                        | <b>version PTP</b>  |
| 2               | version Network    | message Length                  |                     |
| 3               |                    |                                 |                     |

Table 7-74 V1 and V2 PTP Message Structure (Continued)

| Offset in Bytes | V1 Fields                       | V2 Fields                |
|-----------------|---------------------------------|--------------------------|
| Bits            | 7 6 5 4 3 2 1 0                 | 7 6 5 4 3 2 1 0          |
| 4               | Subdomain                       | domain Number            |
| 5               |                                 | Reserved                 |
| 6               |                                 | flags                    |
| 7               |                                 |                          |
| 8               |                                 |                          |
| 9               |                                 |                          |
| 10              |                                 | correction Field         |
| 11              |                                 |                          |
| 12              |                                 |                          |
| 13              |                                 |                          |
| 14              |                                 |                          |
| 15              |                                 |                          |
| 16              |                                 | reserved                 |
| 17              |                                 |                          |
| 18              |                                 |                          |
| 19              |                                 |                          |
| 20              | message Type                    | Source Port Identity     |
| 21              | Source communication technology |                          |
| 22              | Source UUID                     |                          |
| 23              |                                 |                          |
| 24              |                                 |                          |
| 25              |                                 |                          |
| 26              |                                 |                          |
| 27              |                                 |                          |
| 28              | source port id                  |                          |
| 29              |                                 |                          |
| 30              | <b><i>sequenceId</i></b>        | <b><i>sequenceId</i></b> |
| 31              |                                 |                          |
| 32              | <b><i>control</i></b>           | control                  |
| 33              | reserved                        | Log Message Interval     |
| 34              | flags                           | N/A                      |
| 35              |                                 |                          |

1. Should be all zero.

**Note:** Only the fields with the bold italic format colored red are of interest to the hardware.

|---------------|-----------------|---------------|-------------|

Table 7-76 PTP Message Over Layer 4

|               |         |     |             |
|---------------|---------|-----|-------------|
| Ethernet (L2) | IP (L3) | UDP | PTP message |
|---------------|---------|-----|-------------|

When a PTP packet is recognized (by Ethertype or UDP port address) on the receive side then if the version is V1 then the Control field at offset 32 should be compared to the TSYNCRXCFG.CTRLT message field (see [Section 8.16.26](#)) otherwise the byte at offset zero should be used for comparison to the TSYNCRXCFG.MSGT field. The rest of the required fields are at the same location and size for both V1 and V2.

**Table 7-77 Message Decoding for V1 (Control Field at Offset 32)**

| Enumeration            | Value |
|------------------------|-------|
| PTP_SYNC_MESSAGE       | 0     |
| PTP_DELAY_REQ_MESSAGE  | 1     |
| PTP_FOLLOWUP_MESSAGE   | 2     |
| PTP_DELAY_RESP_MESSAGE | 3     |
| PTP_MANAGEMENT_MESSAGE | 4     |
| reserved               | 5-255 |

**Table 7-78 Message Decoding for V2 (Message ID Field at Offset 0)**

| Message ID                      | Message Type | Value (hex) |
|---------------------------------|--------------|-------------|
| PTP_SYNC_MESSAGE                | Event        | 0           |
| PTP_DELAY_REQ_MESSAGE           | Event        | 1           |
| PTP_PATH_DELAY_REQ_MESSAGE      | Event        | 2           |
| PTP_PATH_DELAY_RESP_MESSAGE     | Event        | 3           |
| Unused                          | Event        | 4-7         |
| PTP_FOLLOWUP_MESSAGE            | General      | 8           |
| PTP_DELAY_RESP_MESSAGE          | General      | 9           |
| PTP_PATH_DELAY_FOLLOWUP_MESSAGE | General      | A           |
| PTP_ANNOUNCE_MESSAGE            | General      | B           |
| PTP_SIGNALLING_MESSAGE          | General      | C           |
| PTP_MANAGEMENT_MESSAGE          | General      | D           |
| Unused                          | General      | E-F         |

If V2 mode is configured in the TSYNCRXCTL.Type field (see [Section 8.16.1](#)) then the time stamp should be taken on PTP\_PATH\_DELAY\_REQ\_MESSAGE and PTP\_PATH\_DELAY\_RESP\_MESSAGE according to the value in the TSYNCRXCFG.MSGT message field described in [Section 8.16.26](#).

## 7.10 Statistic Counters

The I350 supports different statistic counters as described in [Section 8.18](#). The statistic counters can be used to create statistic reports as required by different standards. The I350 statistic counters allow support for the following standards:

- IEEE 802.3 clause 30 management – DTE section.
- NDIS 6.0 OID\_GEN\_STATISTICS.
- RFC 2819 – RMON Ethernet statistics group.
- Linux Kernel (version 2.6) net\_device\_stats

The following section describes the match between the internal the I350 statistic counters and the counters requested by the different standards.

## 7.10.1 IEEE 802.3 clause 30 management

The I350 supports the Basic and Mandatory Packages defined in clause 30 of the IEEE 802.3 spec. The following table describes the matching between the internal statistics and the counters requested by these packages.

**Table 7-79 IEEE 802.3 Mandatory Package Statistics**

| Mandatory package capability | I350 counter | Notes and limitations                          |
|------------------------------|--------------|------------------------------------------------|
| FramesTransmittedOK          | GPTC         | The I350 doesn't include flow control packets. |
| SingleCollisionFrames        | SCC          |                                                |
| MultipleCollisionFrames      | MCC          |                                                |
| FramesReceivedOK             | GPRC         | The I350 doesn't include flow control packets. |
| FrameCheckSequenceErrors     | CRCERRS      |                                                |
| AlignmentErrors              | ALGNERRC     |                                                |

In addition, part of the recommended package is also implemented as described in the following table

**Table 7-80 IEEE 802.3 Recommended Package Statistics**

| Recommended package capability | I350 counter    | Notes and limitations                                                                                                                             |
|--------------------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| OctetsTransmittedOK            | GOTCH/GOTCL     | The I350 counts also the DA/SA/LT/CRC as part of the octets. The I350 doesn't count Flow control packets.                                         |
| FramesWithDeferredXmissions    | DC              |                                                                                                                                                   |
| LateCollisions                 | LATECOL         |                                                                                                                                                   |
| FramesAbortedDueToXSColls      | ECOL            |                                                                                                                                                   |
| FramesLostDueToIntMACXmitError | HTDMPC          | The I350 counts the excessive collisions in this counter, while 802.3 increments no other counters, while this counter is incremented             |
| CarrierSenseErrors             | TNCRS           | The I350 doesn't count cases of CRS de-assertion in the middle of the packet. However, such cases are not expected when the internal PHY is used. |
| OctetsReceivedOK               | TORL+TORH       | The I350 counts also the DA/SA/LT/CRC as part of the octets. Doesn't count Flow control packets.                                                  |
| FramesLostDueToIntMACRcvError  | RNBC            |                                                                                                                                                   |
| SQETestErrors                  | N/A             |                                                                                                                                                   |
| MACControlFramesTransmitted    | N/A             |                                                                                                                                                   |
| MACControlFramesReceived       | N/A             |                                                                                                                                                   |
| UnsupportedOpcodesReceived     | FCURC           |                                                                                                                                                   |
| PAUSEMACCtrlFramesTransmitted  | XONTXC + XOFTXC |                                                                                                                                                   |
| PAUSEMACCtrlFramesReceived     | XONRXC + XOFRXC |                                                                                                                                                   |

Part of the optional package is also implemented as described in the following table

**Table 7-81 IEEE 802.3 Optional Package Statistics**

| Optional package capability | I350 counter | Notes                                 |
|-----------------------------|--------------|---------------------------------------|
| MulticastFramesXmittedOK    | MPTC         | The I350 doesn't count FC packets     |
| BroadcastFramesXmittedOK    | BPTC         |                                       |
| MulticastFramesReceivedOK   | MPRC         | The I350 doesn't count FC packets     |
| BroadcastFramesReceivedOK   | BPRC         |                                       |
| InRangeLengthErrors         | LENERRS      |                                       |
| OutOfRangeLengthField       | N/A          | Packets parsed as Ethernet II packets |
| FrameTooLongErrors          | ROC + RJC    |                                       |

## 7.10.2 OID\_GEN\_STATISTICS

The I350 supports the part of the OID\_GEN\_STATISTICS as defined by Microsoft\* NDIS 6.0 spec. The following table describes the matching between the internal statistics and the counters requested by this structure.

**Table 7-82 Microsoft\* OID\_GEN\_STATISTICS**

| OID entry              | I350 counters                                   | Notes |
|------------------------|-------------------------------------------------|-------|
| ifInDiscards;          | CRCERRS + RLEC + RXERRC + MPC + RNBC + ALGNERRC |       |
| ifInErrors;            | CRCERRS + RLEC + RXERRC + ALGNERRC              |       |
| ifHCInOctets;          | GORCL/GOTCL                                     |       |
| ifHCInUcastPkts;       | GPRC - MPRC - BPRC                              |       |
| ifHCInMulticastPkts;   | MPRC                                            |       |
| ifHCInBroadcastPkts;   | BPRC                                            |       |
| ifHCOctets;            | GOTCL/GOTCH                                     |       |
| ifHCOUcastPkts;        | GPTC - MPTC - BPTC                              |       |
| ifHCOmulticastPkts;    | MPTC                                            |       |
| ifHCObroadcastPkts;    | BPTC                                            |       |
| ifOutErrors;           | ECOL + LATECOL                                  |       |
| ifOutDiscards;         | ECOL                                            |       |
| ifHCInUcastOctets;     | N/A                                             |       |
| ifHCInMulticastOctets; | N/A                                             |       |
| ifHCInBroadcastOctets; | N/A                                             |       |
| ifHCOUcastOctets;      | N/A                                             |       |
| ifHCOmulticastOctets;  | N/A                                             |       |
| ifHCObroadcastOctets;  | N/A                                             |       |

## 7.10.3 RMON

The I350 supports the part of the RMON Ethernet statistics group as defined by IETF RFC 2819. The following table describes the matching between the internal statistics and the counters requested by this group.

**Table 7-83 RMON Statistics**

| RMON statistic                 | I350 counters             | Notes                                      |
|--------------------------------|---------------------------|--------------------------------------------|
| etherStatsDropEvents           | <i>MPC + RNBC</i>         |                                            |
| etherStatsOctets               | <i>TOTL + TOTH</i>        |                                            |
| etherStatsPkts                 | <i>TPR</i>                |                                            |
| etherStatsBroadcastPkts        | <i>BPRC</i>               |                                            |
| etherStatsMulticastPkts        | <i>MPRC</i>               | The I350 don't count FC packets            |
| etherStatsCRCAlignErrors       | <i>CRCERRS + ALGNERRC</i> |                                            |
| etherStatsUndersizePkts        | <i>RUC</i>                |                                            |
| etherStatsOversizePkts         | <i>ROC</i>                |                                            |
| etherStatsFragments            | <i>RFC</i>                | Should count bad aligned fragments as well |
| etherStatsJabbers              | <i>RJC</i>                | Should count bad aligned jabbers as well   |
| etherStatsCollisions           | <i>COLC</i>               |                                            |
| etherStatsPkts64Octets         | <i>PRC64</i>              | RMON counts bad packets as well            |
| etherStatsPkts65to127Octets    | <i>PRC127</i>             | RMON counts bad packets as well            |
| etherStatsPkts128to255Octets   | <i>PRC255</i>             | RMON counts bad packets as well            |
| etherStatsPkts256to511Octets   | <i>PRC511</i>             | RMON counts bad packets as well            |
| etherStatsPkts512to1023Octets  | <i>PRC1023</i>            | RMON counts bad packets as well            |
| etherStatsPkts1024to1518Octets | <i>PRC1522</i>            | RMON counts bad packets as well            |

## 7.10.4 Linux\* net\_device\_stats

The I350 supports part of the net\_device\_stats as defined by Linux\* Kernel version 2.6 (defined in <linux/netdevice.h>). The following table describes the matching between the internal statistics and the counters requested by this structure./

**Table 7-84 Linux net\_device\_stats**

| net_device_stats field | I350 counters                             | Notes                                                                                               |
|------------------------|-------------------------------------------|-----------------------------------------------------------------------------------------------------|
| rx_packets             | <i>GPRC</i>                               | The I350 doesn't count flow controls - can be accounted for by using the XONRXC and XOFRXC counters |
| tx_packets             | <i>GPTC</i>                               | The I350 doesn't count flow controls - can be accounted for by using the XONTXC and XOFTXC counters |
| rx_bytes               | <i>GORCL + GORCH</i>                      |                                                                                                     |
| tx_bytes               | <i>GOTCL + GOTCH</i>                      |                                                                                                     |
| rx_errors              | <i>CRCERRS + RLEC + RXERRC + ALGNERRC</i> |                                                                                                     |

## 7.10.5 Statistics Hierarchy.

The following diagram describes the relations between the packet flow and the different statistic counters.

Figure 7-30 Flow Statistics

§ §

## 8 Programming Interface

### 8.1 Introduction

This chapter details the programmer visible state inside the I350. In some cases, it describes hardware structures invisible to software in order to clarify a concept. The I350's address space is mapped into four regions with PCI Base Address Registers described in [Section 9.4.11](#). These regions are listed in the table below.

**Table 8-1 Address Space Regions**

| Addressable Content                                   | How Mapped           | Size of Region                 |
|-------------------------------------------------------|----------------------|--------------------------------|
| Internal registers, memories and FLASH ("Memory BAR") | Direct memory-mapped | 128K + FLASH Size <sup>1</sup> |
| Flash (optional)                                      | Direct memory-mapped | 64K-8M                         |
| Expansion ROM (optional)                              | Direct memory-mapped | 64K-8M <sup>1</sup>            |
| Internal registers and memories, Flash (optional)     | I/O Window mapped    | 32 bytes <sup>2</sup>          |
| MSI-X (optional)                                      | Direct memory-mapped | 16K                            |

1. The FLASH space in the "Memory CSR" and Expansion ROM Base Address map the same FLASH memory. Accessing the "memory BAR" at offset 128K and Expansion ROM at offset 0x0 are mapped to the FLASH device at offset 0x0.
2. The internal registers and memories can be accessed through I/O space indirectly as explained below.

The internal register/memory space is described in the following sections. The PHY registers are accessed through the MDIO interface.

#### 8.1.1 Memory, I/O Address and Configuration Decoding

##### 8.1.1.1 Memory-Mapped Access to Internal Registers and Memories

The internal registers and memories might be accessed as direct memory-mapped offsets from the base address register (BAR0 or BAR 0/1; refer to [Section 9.4.11](#)). Refer to [Section 8.1.3](#) for the appropriate offset for each specific internal register.

In IOV mode, this area is partially duplicated per VF. All replications contain only the subset of the register set that is available for VF programming.

### 8.1.1.2 Memory-Mapped Access to Flash

The external Flash may be accessed using direct memory-mapped offsets from the Memory base address register (BAR0 in 32bit addressing or BAR0/BAR1 in 64 bit addressing; refer to [Section 9.4.11](#)). For accesses, the offset from the Memory BAR minus 128KB corresponds to the physical address within the external Flash device. Memory mapped accesses to the external Flash are enabled when the value of the *Flash Size* field in the EEPROM (refer to [Section 6.2.26](#)) is not 000b.

### 8.1.1.3 Memory-Mapped Access to MSI-X Tables

The MSI-X tables may be accessed as direct memory-mapped offsets from the base address register (BAR3; refer to [Section 9.4.11](#)). Refer to [Section 8.1.3](#) for the appropriate offset for each specific internal MSIX register.

In IOV mode, this area is duplicated per VF.

### 8.1.1.4 Memory-Mapped Access to Expansion ROM

The external Flash might also be accessed as a memory-mapped expansion ROM. Accesses to offsets starting from the Expansion ROM Base address (refer to [Section 9.4.11](#)) reference the Flash provided that access is enabled thorough the *LAN Boot Disable* bit in the *Initialization Control 3* EEPROM word, and if the Expansion ROM Base Address register contains a valid (non-zero) base memory address.

### 8.1.1.5 I/O-Mapped Access to Internal Registers and Memories

To support pre-boot operation (prior to the allocation of physical memory base addresses), all internal registers and memories can be accessed using I/O operations. I/O accesses are supported only if an I/O Base Address is allocated and mapped (BAR2; refer to [Section 9.4.11](#)), the BAR contains a valid (non-zero value), and I/O address decoding is enabled in the PCIe configuration.

When an I/O BAR is mapped, the I/O address range allocated opens a 32-byte “window” in the system I/O address map. Within this window, two I/O addressable registers are implemented: IOADDR and IODATA. The IOADDR register is used to specify a reference to an internal register or memory, and then the IODATA register is used as a “window” to the register or memory address specified by IOADDR:

**Table 8-2 IOADDR and IODATA in I/O Address Space**

| Offset      | Abbreviation | Name                                                                                                                                                                                | RW | Size    |
|-------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|---------|
| 0x00        | IOADDR       | Internal Register or Internal Memory location address.<br>0x00000-0x1FFFF – Internal Registers and Memories<br>0x20000-0xFFFFFFFF – Undefined                                       | RW | 4 bytes |
| 0x04        | IODATA       | Data field for reads or writes to the Internal Register or Internal Memory Location as identified by the current value in IOADDR. All 32 bits of this register are read/write-able. | RW | 4 bytes |
| 0x08 – 0x1F | Reserved     | Reserved                                                                                                                                                                            | RO | 4 bytes |

#### 8.1.1.5.1 IOADDR (I/O offset 0x00)

The IOADDR register must always be written as a DWORD access. Writes that are less than 32 bits are ignored. Reads of any size return a DWORD of data; however, the chipset or CPU might only return a subset of that DWORD.

For software programmers, the IN and OUT instructions must be used to cause I/O cycles to be used on the PCIe bus. Because writes must be to a 32-bit quantity, the source register of the OUT instruction must be EAX (the only 32-bit register supported by the OUT command). For reads, the IN instruction can have any size target register, but it is recommended that the 32-bit EAX register be used.

Because only a particular range is addressable, the upper bits of this register are hard coded to zero. Bits 31 through 20 are not write-able and always read back as 0b.

At hardware reset (LAN\_PWR\_GOOD) or PCI Reset, this register value resets to 0x00000000. Once written, the value is retained until the next write or reset.

#### 8.1.1.5.2 IODATA (I/O offset 0x04)

The IODATA register must always be written as a DWORD access when the IOADDR register contains a value for the Internal Register and Memories (for example, 0x00000-0x1FFFC). In this case, writes that are less than 32 bits are ignored.

Reads to IODATA of any size returns a DWORD of data. However, the chipset or CPU might only return a subset of that DWORD.

For software programmers, the IN and OUT instructions must be used to cause I/O cycles to be used on the PCIe bus. Where 32-bit quantities are required on writes, the source register of the OUT instruction must be EAX (the only 32-bit register supported by the OUT command).

Writes and reads to IODATA when the IOADDR register value is in an undefined range (0x20000-0xFFFFF) should not be performed. Results cannot be determined.

**Notes:** There are no special software timing requirements on accesses to IOADDR or IODATA. All accesses are immediate, except when data is not readily available or acceptable. In this case, the I350 delays the results through normal bus methods (for example, split transaction or transaction retry).

Because a register/memory read or write takes two IO cycles to complete, software must provide a guarantee that the two IO cycles occur as an atomic operation. Otherwise, results can be non-deterministic from the software viewpoint.

Software should access CSRs via IO address space or Configuration address space but should not use both mechanisms at the same time.

#### 8.1.1.5.3 Undefined I/O Offsets

I/O offsets 0x08 through 0x1F are considered to be reserved offsets with the I/O window. Dword reads from these addresses returns 0xFFFF; writes to these addresses are discarded.

#### 8.1.1.6 Configuration Access to Internal Registers and Memories

To support 'legacy' pre-boot 16-bit operating environments without requiring IO address space, the I350 enables accessing CSRs via configuration address space by mapping the IOADDR and IODATA registers into configuration address space. The registers mapping in this case is shown in [Table 8-3](#).

**Table 8-3 IOADDR and IODATA in Configuration Address space**

| Configuration Address | Abbreviation | Name                                                                                                                                                                                | RW | Size    |
|-----------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|---------|
| 0x98                  | IOADDR       | Internal register or internal memory location address.<br>0x00000-0x1FFFF – Internal Registers and Memories<br>0x20000-0x7FFFF – Undefined                                          | RW | 4 bytes |
| 0x9C                  | IODATA       | Data field for reads or writes to the internal register or internal memory location as identified by the current value in IOADDR. All 32 bits of this register are read/write-able. | RW | 4 bytes |

Software writes data to an internal CSR via Configuration space in the following manner:

1. CSR address is written to the IOADDR register where:
  - a. Bit 31 (IOADDR.Configuration IO Access Enable) of the IOADDR register should be set to 1.
  - b. Bits 30:0 of IOADDR should hold the actual address of the internal register or memory being written to.
2. Data to be written is written into the IODATA register.
  - The IODATA register is used as a “window” to the register or memory address specified by IOADDR register. As a result the data written to the IODATA register is written into the CSR pointed to by bits 30:0 of the IOADDR register.
3. IOADDR.Configuration IO Access Enable is cleared, to avoid un-intentional CSR read operations (that may cause clear by read) by other applications scanning the configuration space.

Software reads data from an internal CSR via Configuration space in the following manner:

1. CSR address is written to the IOADDR register where:
  - a. Bit 31 (IOADDR.Configuration IO Access Enable) of the IOADDR register should be set to 1.
  - b. Bits 30:0 of IOADDR should hold the actual address of the internal register or memory being read.
2. CSR value is read from the IODATA register.
  - a. The IODATA register is used as a “window” to the register or memory address specified by IOADDR register. As a result the data read from the IODATA register is the data of the CSR pointed to by bits 30:0 of the IOADDR register
3. IOADDR.Configuration IO Access Enable is cleared, to avoid un-intentional CSR read operations (that may cause clear by read) by other applications scanning the configuration space.

#### Notes:

- In the event that the CSR\_conf\_en bit in the PCIe Init Configuration 2 EEPROM word is cleared, accesses to the IOADDR and IODATA registers via the configuration address space are ignored and have no effect on the register and the CSRs referenced by the IOADDR register. In this case any read access to these registers returns a value of 0.
- When Function is in D3 state Software should not attempt to access CSRs via the IOADDR and IODATA Configuration registers.
- To enable CSR access via configuration space, Software should set to 1 bit 31 (IOADDR.Configuration IO Access Enable) of the IOADDR register. Software should clear bit 31 of the IOADDR register after completing CSR access to avoid an unintentional “clear by read” operation, by another application scanning the configuration address space.
- Bit 31 of the IOADDR register (IOADDR.Configuration IO Access Enable) has no effect when initiating access via IO Address space.

- Software should access CSRs via IO address space or Configuration address space but should not use both mechanisms at the same time.

## 8.1.2 Register Conventions

All registers in the I350 are defined to be 32 bits, should be accessed as 32 bit double-words, There are some exceptions to this rule:

- Register pairs where two 32 bit registers make up a larger logical size
- Accesses to Flash memory (via Expansion ROM space, secondary BAR space, or the I/O space) might be byte, word or double word accesses.

**Reserved bit positions:** Some registers contain certain bits that are marked as “reserved”. These bits should never be set to a value of “one” by software. Reads from registers containing reserved bits might return indeterminate values in the reserved bit-positions unless read values are explicitly stated. When read, these reserved bits should be ignored by software.

**Reserved and/or undefined addresses:** any register address not explicitly declared in this specification should be considered to be reserved, and should not be written to. Writing to reserved or undefined register addresses might cause indeterminate behavior. Reads from reserved or undefined configuration register addresses might return indeterminate values unless read values are explicitly stated for specific addresses.

**Initial values:** most registers define the initial hardware values prior to being programmed. In some cases, hardware initial values are undefined and is listed as such via the text “undefined”, “unknown”, or “X”. Such configuration values might need to be set via EEPROM configuration or via software in order for proper operation to occur; this need is dependent on the function of the bit. Other registers might cite a hardware default which is overridden by a higher-precedence operation. Operations which might supersede hardware defaults might include a valid EEPROM load, completion of a hardware operation (such as hardware auto-negotiation), or writing of a different register whose value is then reflected in another bit.

For registers that should be accessed as 32 bit double words, partial writes (less than a 32 bit double word) do not take effect (the write is ignored). Partial reads returns all 32 bits of data regardless of the byte enables.

**Note:** Partial reads to read-on-clear registers (*ICR*) can have unexpected results since all 32 bits are actually read regardless of the byte enables. Partial reads should not be done.

All statistics registers are implemented as 32 bit registers. Though some logical statistics registers represent counters in excess of 32-bits in width, registers must be accessed using 32-bit operations (for example, independent access to each 32-bit field). When reading 64 bits statistics registers the least significant 32 bit register should be read first.

See special notes for VLAN Filter Table, Multicast Table Arrays and Packet Buffer Memory which appear in the specific register definitions.

The I350 register fields are assigned one of the attributes described in [Table 8-4](#).

**Table 8-4 I350 Register Field Attributes**

| Attribute | Description                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RW        | Read-Write field: Register bits are read-write and can be either set or cleared by software to the desired state.                                                                                                                                                    |
| RWS       | Read-Write Status field: Register bits are read-write and can be either set or cleared by software to the desired state. However, the value of this field might be changed by the hardware to reflect a status change.                                               |
| RO        | Read-only register: Register bits are read-only and should not be altered by software. Register bits might be initialized by hardware mechanisms such as pin strapping, serial EEPROM or reflect a status of the hardware state.                                     |
| R/W1C     | Read-only status, Write-1-to-clear status register: Register bits indicate status when read, a set bit indicating a status event can be cleared by writing a 1b. Writing a 0b to R/W1C bit has no effect.                                                            |
| Rsv       | Reserved. Write 0 to these fields and ignore read.                                                                                                                                                                                                                   |
| RC        | Read-only status, Read-to-clear status register: Register bits indicate status when read, a set bit indicating a status event is cleared by reading it.                                                                                                              |
| SC        | Self Clear field: a command field that is self clearing. These field are always read as zero.                                                                                                                                                                        |
| WO        | Write only field: a command field that can not be read, These field read values are undefined.                                                                                                                                                                       |
| RC/W      | Read-Write status, Read-to-clear status register: Read-to-clear status register. Register bits indicate status when read. Register bits are read-write and can be either set or cleared by software to the desired state.                                            |
| RC/W1C    | Read-only status, Write-1-to-clear status register: Read-to-clear status register. Register bits indicate status when read, a set bit indicating a status event can be cleared by writing a 1b or by reading the register. Writing a 0b to RC/W1C bit has no effect. |
| RS        | Read Set – This is the attribute used for Semaphore bits. These bits are set by read in case the previous values were zero. In this case the read value is zero; otherwise the read value is one. Cleared by write zero.                                             |

PHY registers described in [Section 8.26](#) use a special nomenclature to define the read/write mode of individual bits in each register. See table below for details.

**Table 8-5 PHY Register Nomenclature**

| Register Mode | Description                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LH            | Latched High. Event is latched and erased when read.                                                                                                                                                          |
| LL            | Latched Low. Event is latched and erased when read. For example, Link Loss is latched when the PHY Control Register bit 2 = 0b. After read, if the link is good, the PHY Control Register bit 2 is set to 1b. |
| RO            | Read Only.                                                                                                                                                                                                    |
| R/W           | Read and Write.                                                                                                                                                                                               |
| SC            | Self-Clear. The bit is set, automatically executed, and then reset to normal operation.                                                                                                                       |
| CR            | Clear after Read. For example, 1000BASE-T Status Register bits 7:0 (Idle Error Counter).                                                                                                                      |
| Update        | Value written to the register bit does not take effect until software PHY reset is executed.                                                                                                                  |

**Note:** For all binary equations appearing in the register map, the symbol “|” is equivalent to a binary OR operation.

### 8.1.2.1 Registers Byte Ordering

This section defines the structure of registers that contain fields carried over the network. Some examples are L2, L3 and L4 fields.

The following example is used to describe byte ordering over the wire (hex notation):

LastFirst  
 ..., 06, 05, 04, 03, 02, 01, 00

Each byte is sent with the LSbit first. That is, the bit order over the wire for this example is

Last First

..., 0000 0011, 0000 0010, 0000 0001, 0000 0000

The general rule for register ordering is to use Host Ordering (also called little endian). Using the above example, a 6-byte fields (MAC address) is stored in a CSR in the following manner:

|                      | Byte 3 | Byte 2 | Byte 1 | Byte0 |
|----------------------|--------|--------|--------|-------|
| DW address (N)       | 0x03   | 0x02   | 0x01   | 0x00  |
| DW address (N+4) ... | ...    | ...    | 0x05   | 0x04  |

The exceptions listed below use network ordering (also called big endian). Using the above example, a 16-bit field (EtherType) is stored in a CSR in the following manner:

|                | Byte 3 | Byte 2 | Byte 1 | Byte0 |
|----------------|--------|--------|--------|-------|
| (DW aligned)   | ...    | ...    | 0x00   | 0x01  |
| or             |        |        |        |       |
| (Word aligned) | 0x00   | 0x01   | ...    | ...   |

The following exceptions use network ordering:

All ETHERType fields. For example, the VET EXT field in the VET register, the EType field in the ETQF register, the EType field in the METF register.

**Note:** The “normal” notation as it appears in text books, etc. is to use network ordering. Example: Suppose a MAC address of 00-A0-C9-00-00-00. The order on the network is 00, then A0, then C9, etc. However, the host ordering presentation would be:

|                      | Byte 3 | Byte 2 | Byte 1 | Byte0 |
|----------------------|--------|--------|--------|-------|
| DW address (N)       | 00     | C9     | A0     | 00    |
| DW address (N+4) ... | ...    | ...    | 00     | 00    |

## 8.1.3 Register Summary

All the I350's non-PCIe configuration registers, except for the MSI-X register, are listed in the table below. These registers are ordered by grouping and are not necessarily listed in order that they appear in the address space. In an IOV system, this list refers to the PF registers, the VF register space is listed in [Section 8.27](#).

**Table 8-6 Register Summary**

| Offset         | Alias Offset | Abbreviation | Name                             | RW |
|----------------|--------------|--------------|----------------------------------|----|
| <b>General</b> |              |              |                                  |    |
| 0x0000         | 0x0004       | CTRL         | Device Control Register          | RW |
| 0x0008         | N/A          | STATUS       | Device Status Register           | RO |
| 0x0018         | N/A          | CTRL_EXT     | Extended Device Control Register | RW |
| 0x0020         | N/A          | MDIC         | MDI Control Register             | RW |
| 0x0E08         | N/A          | P1GCTRL0     | Serdes Control 0                 | RW |

**Table 8-6 Register Summary (Continued)**

| Offset                        | Alias Offset | Abbreviation | Name                                  | RW     |
|-------------------------------|--------------|--------------|---------------------------------------|--------|
| 0x0028                        | N/A          | FCAL         | Flow Control Address Low              | RO     |
| 0x002C                        | N/A          | FCAH         | Flow Control Address High             | RO     |
| 0x0030                        | N/A          | FCT          | Flow Control Type                     | RW     |
| 0x0034                        | N/A          | CONNSW       | Copper/Fiber switch control           | RW     |
| 0x0038                        | N/A          | VET          | VLAN Ether Type                       | RW     |
| 0x0E04                        | N/A          | MDICNFG      | MDC/MDIO Configuration Register       | RW     |
| 0x0170                        | N/A          | FCTTV        | Flow Control Transmit Timer Value     | RW     |
| 0x0E00                        | N/A          | LEDCTL       | LED Control Register                  | RW     |
| 0x1028                        | N/A          | I2CCMD       | SFP I2C command                       | RW     |
| 0x102C                        | N/A          | I2CPARAMS    | SFP I2C Parameter                     | RW     |
| 0x1040                        | N/A          | WDSTP        | Watchdog setup register               | RW     |
| 0x1044                        | N/A          | WDSWSTS      | Watchdog Software                     | RW     |
| 0x1048                        | N/A          | FRTIMER      | Free Running Timer                    | RWS    |
| 0x104C                        | N/A          | TCPTimer     | TCP timer                             | RW     |
| 0x5B70                        | N/A          | DCA_ID       | DCA Requester ID Information Register | RO     |
| 0x5B50                        | N/A          | SWSM         | Software Semaphore Register           | RW     |

### 8.1.3.1 Alias Addresses

Certain registers maintain an alias address designed for backward compatibility with software written for previous GbE controllers. For these registers, the alias address is shown in the table above. Those registers can be accessed by software at either the new offset or the alias offset. It is recommended that software that is written solely for the I350, use the new address offset.

**Note:**

## 8.1.4 MSI-X BAR Register Summary

Table 8-7 MSI-X Register Summary

| Category    | Offset                        | Abbreviation | Name                            | RW  | Page                     |

## 8.2 General Register Descriptions

### 8.2.1 Device Control Register - CTRL (0x00000; R/W)

This register, as well as the Extended Device Control register (CTRL\_EXT), controls the major operational modes for the device. While software write to this register to control device settings, several bits (such as FD and SPEED) can be overridden depending on other bit settings and the resultant link configuration determined by the PHY's Auto-Negotiation resolution. See [Section 4.6.7](#) for details on the setup of these registers in the different link modes.

**Note:** This register is also aliased at address 0x0004.

| Field              | Bit(s) | Initial Value   | Description                                                                                                                                                                                                                                                                   |

1. These bits are loaded from EEPROM.

## 8.2.2 Device Status Register - STATUS (0x0008; RO)

| Field | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FD    | 0      | X             | <p>Full Duplex.</p> <p>0 = Half duplex (HD).<br/>1 = Full duplex (FD).</p> <p>Reflects duplex setting of the MAC and/or link.</p> <p>FD reflects the actual MAC duplex configuration. This normally reflects the duplex setting for the entire link, as it normally reflects the duplex configuration negotiated between the PHY and link partner (copper link) or MAC and link partner (fiber link).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| LU    | 1      | X             | <p>Link up.</p> <p>0 = no link established;<br/>1 = link established.</p> <p>For this bit to be valid, the Set Link Up bit of the Device Control Register (<i>CTRL.SLU</i>) must be set.</p> <p>Link up provides a useful indication of whether something is attached to the port. Successful negotiation of features/link parameters results in link activity. The link startup process (and consequently the duration for this activity after reset) can be several 100's of ms. When the internal PHY is used, this reflects whether the PHY's LINK indication is present. When the SerDes, SGMII or 1000BASE-KX interface is used, this indicates loss-of-signal; if Auto-Negotiation is also enabled, this can also indicate successful Auto-Negotiation. Refer to <a href="#">Section 3.7.4</a> for more details.</p> <p>Note: Bit is valid only when working in Internal PHY mode. In SerDes mode bit is always 0.</p> |

| Field                    | Bit(s) | Initial Value                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Reserved    | 5:4    | 00b              | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                        |
| SDP2_DATA   | 6      | 0b <sup>1</sup>  | SDP2 Data Value. Used to read (write) the value of software-controllable IO pin SDP2. If SDP2 is configured as an output (SDP2_IODIR = 1b), this bit controls the value driven on the pin (initial value EEPROM-configurable). If SDP2 is configured as an input, reads return the current value of the pin. |
| SDP3_DATA   | 7      | 0b <sup>1</sup>  | SDP3 Data Value. Used to read (write) the value of software-controllable IO pin SDP3. If SDP3 is configured as an output (SDP3_IODIR = 1b), this bit controls the value driven on the pin (initial value EEPROM-configurable). If SDP3 is configured as an input, reads return the current value of the pin. |
| Reserved    | 9:8    | 0x0 <sup>1</sup> | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                        |
| SDP2_IODIR  | 10     | 0b <sup>1</sup>  | SDP2 Pin Direction. Controls whether software-controllable pin SDP2 is configured as an input or output (0b = input, 1b = output). Initial value is EEPROM-configurable. This bit is not affected by software or system reset, only by initial power-on or direct software writes.                           |
| SDP3_IODIR  | 11     | 0b <sup>1</sup>  | SDP3 Pin Direction. Controls whether software-controllable pin SDP3 is configured as an input or output (0b = input, 1b = output). Initial value is EEPROM-configurable. This bit is not affected by software or system reset, only by initial power-on or direct software writes.                           |
| ASDCHK      | 12     | 0b               | ASD Check<br>Initiates an Auto-Speed-Detection (ASD) sequence to sense the frequency of the PHY receive clock (RX_CLK). The results are reflected in STATUS.ASDV. This bit is self-clearing.                                                                                                                 |
| EE_RST (SC) | 13     | 0b               | EEPROM Reset<br>When set, initiates a reset-like event to the EEPROM function. This causes an EEPROM Auto-load operation as if a software reset ( <i>CTRL.RST</i> ) had occurred. This bit is self-clearing.                                                                                                 |
| PFRSTD (SC) | 14     | 0b               | PF reset Done.<br>When set, the RSTI bit in all the VFMailbox registers is cleared and the RSTD bit in all the VFMailbox regs is set (Refer to <a href="#">Section 4.6.11.2.3</a> for additional information).                                                                                               |

| I2C Enabled              | 25     | 0b <sup>1</sup>                        | Enable I2C<br>This bit enables the SFPx_I2C pins that can be used to access external SFP modules or an external 1000BASE-T PHY via the MDIO interface. If cleared, the SFPx_I2C pads are isolated and accesses to the SFPx_I2C pins through the <i>I2CCMD</i> register or the <i>MDIC</i> register are ignored.                                                                                                                                                                                                                                                                                                                                                                         |
| EXT_VLAN                 | 26     | 0b <sup>1</sup>                        | External VLAN Enable<br>When set, all incoming Rx packets are expected to have at least one VLAN with the Ether type as defined in <i>VET.EXT_VET</i> that should be ignored. The packets can have a second internal VLAN that should be used for all filtering purposes. All Tx packets are expected to have at least one VLAN added to them by the host. In the case of an additional VLAN request ( <i>VLE</i> - VLAN Enable is set in transmit descriptor) the second VLAN is added after the first external VLAN is added by the host. This bit is reset only by a power up reset or by an EEPROM full auto load and should only be changed while Tx and Rx processes are stopped. |

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                             |
|----------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved | 27     | 0b            | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                   |
| DRV_LOAD | 28     | 0b            | Driver Loaded<br>This bit should be set by the driver after it is loaded. This bit should be cleared when the driver unloads or after a PCIe reset. The Management controller reads this bit to indicate to the manageability controller (BMC) that the driver has loaded.<br><b>Note:</b> Bit is reset on Power-up or PCIe reset only. |
| Reserved | 31:29  | 0b            | Reserved<br>Write 0, Ignore on read.                                                                                                                                                                                                                                                                                                    |

1. These bits are read from the EEPROM.
2. Default value for SerDes only SKU.

The I350 allows up to four externally controlled interrupts. All software-definable pins, these can be mapped for use as GPI interrupt bits. Mappings are enabled by the SDPx\_GPIEN bits only when these signals are also configured as inputs via SDPx\_IODIR. When configured to function as external interrupt pins, a GPI interrupt is generated when the corresponding pin is sampled in an active-high state.

The bit mappings are shown in the table below for clarity.

**Table 8-8 Mappings for SDI Pins Used as GPI**

| SDP Pin Used as GPI | CTRL_EXT Field Settings |                         | Resulting ICR Bit (GPI) |
|---------------------|-------------------------|-------------------------|-------------------------|
|                     | Direction               | Enable as GPI interrupt |                         |
| 3                   | SDP3_IODIR              | SDP3_GPIEN              | 14                      |
| 2                   | SDP2_IODIR              | SDP2_GPIEN              | 13                      |
| 1                   | SDP1_IODIR              | SDP1_GPIEN              | 12                      |
| 0                   | SDP0_IODIR              | SDP0_GPIEN              | 11                      |

**Note:** If software uses the EE\_RST function and desires to retain current configuration information, the contents of the control registers should be read and stored by software. Control register values are changed by a read of the EEPROM which occurs upon assertion of the EE\_RST bit.

The EEPROM reset function can read configuration information out of the EEPROM which affects the configuration of PCIe space BAR settings. The changes to the BARs are not visible unless the system reboots and the BIOS is allowed to re-map them.

The SPD\_BYPS bit performs a similar function to the CTRL.FRCSPD bit in that the I350's speed settings are determined by the value software writes to the CTRL.SPEED bits. However, with the SPD\_BYPS bit asserted, the settings in CTRL.SPEED take effect immediately rather than waiting until after the I350's clock switching circuitry performs the change.

## 8.2.4 MDI Control Register - MDIC (0x0020; R/W)

Software uses this register to read or write Media Dependent Interface (MDI) registers in the internal PHY or an external SGMII PHY.

| Field         | Bit(s) | Initial Value | Description                                                                                                                                                                                                                           |

1. The default value of the ENRGSR bit in this register is defined in the *Initialization Control 3* (Offset 0x24) EEPROM word (bit 15).

## 8.2.8 VLAN Ether Type - VET (0x0038; R/W)

This register contains the type field hardware matches against to recognize an 802.1Q (VLAN) Ethernet packet. To be compliant with the 802.3ac standard, the *VET.VET* field has a value of 0x8100.

| Field    | Bit(s) | Initial Value | Description               |
|----------|--------|---------------|---------------------------|
| VET (RO) | 15:0   | 0x8100        | VLAN EtherType            |
| VET_EXT  | 31:16  | 0x8100        | External VLAN Ether Type. |

## 8.2.9 LED Control - LEDCTL (0x0E00; RW)

This register controls the setup of the LEDs. Refer to [Section 7.5.1](#) for details of the MODE fields encoding.

| Field             | Bit(s) | Initial Value      | Description                                                                                                                                                                                                                                                                                                                   |

1. These bits are read from the EEPROM.

## 8.3 Internal Packet Buffer Size Registers

The following registers define the size of the on-chip receive and transmit buffers used to receive and transmit packets. The overall available internal buffer size in the I350 for all ports is 144 KB for receive buffers and 80 KB for transmit Buffers. Disabled ports memory can be shared between active ports and sharing can be asymmetric. The default buffer size for each port is loaded from the EEPROM on initialization.

### 8.3.1 Internal Receive Packet Buffer Size - IRPBS (0x2404; RO)

| Field                 | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

1. Value loaded from Initialization Control 4 EEPROM word. In Dual port SKUs, the NVM default should be set to 1 (40 KB).

## 8.4 EEPROM/Flash Register Descriptions

### 8.4.1 EEPROM/Flash Control Register - EEC (0x0010; R/W)

This register provides software direct access to the EEPROM. Software can control the EEPROM by successive writes to this register. Data and address information is clocked into the EEPROM by software toggling the *EE\_SK* and *EE\_DI* bits (0 and 2) of this register with *EE\_CS* set to 0b. Data output from the EEPROM is latched into the *EE\_DO* bit (bit 3) via the internal 62.5 MHz clock and can be accessed by software via reads of this register.

| Field             | Bit(s)             | Initial Value       | Description                                                                                                                                                                                                                                                                                                                          |             |             |                     |               |          |  |       |           |         |       |           |         |
|-------------------|--------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|-------------|---------------------|---------------|----------|--|-------|-----------|---------|-------|-----------|---------|
| EE_SK             | 0                  | 0b                  | Clock input to the EEPROM<br>When <i>EE_GNT</i> = 1b, the <i>EE_SK</i> output signal is mapped to this bit and provides the serial clock input to the EEPROM. Software clocks the EEPROM via toggling this bit with successive writes.                                                                                               |             |             |                     |               |          |  |       |           |         |       |           |         |
| EE_CS             | 1                  | 1b                  | Chip select input to the EEPROM<br>When <i>EE_GNT</i> = 1b, the <i>EE_CS</i> output signal is mapped to the chip select of the EEPROM device. Software enables the EEPROM by writing a 0b to this bit.                                                                                                                               |             |             |                     |               |          |  |       |           |         |       |           |         |
| EE_DI             | 2                  | 1b                  | Data input to the EEPROM<br>When <i>EE_GNT</i> = 1b, the <i>EE_DI</i> output signal is mapped directly to this bit. Software provides data input to the EEPROM via writes to this bit.                                                                                                                                               |             |             |                     |               |          |  |       |           |         |       |           |         |
| EE_DO (RO)        | 3                  | X <sup>1</sup>      | Data output bit from the EEPROM<br>The <i>EE_DO</i> input signal is mapped directly to this bit in the register and contains the EEPROM data output. This bit is RO from a software perspective; writes to this bit have no effect.                                                                                                  |             |             |                     |               |          |  |       |           |         |       |           |         |

1. Value depends on voltage level on *EE\_DO* pin following initialization
2. These bits are read from the EEPROM.

## 8.4.2 EEPROM Read Register - EERD (0x0014; RW)

This register is used by software to cause the I350 to read individual words in the EEPROM. To read a word, software writes the address to the *Read Address* field and simultaneously writes a 1b to the *Start Read* field. The I350 reads the word from the EEPROM and places it in the *Read Data* field, setting the *Read Done* field to 1b. Software can poll this register, looking for a 1b in the *Read Done* field, and then using the value in the *Read Data* field.

When this register is used to read a word from the EEPROM, that word does not influence any of the I350's internal registers even if it is normally part of the auto-read sequence.

**Note:** The EERD register can access only the first 32 KB of the NVM.

**Note:**

| Field     | Bit(s) | Initial Value | Description                                                                                                                                                                                              |
|-----------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| START     | 0      | 0b            | Start Read<br>Writing a 1b to this bit causes the EEPROM to read a (16-bit) word at the address stored in the EE_ADDR field and then storing the result in the EE_DATA field. This bit is self-clearing. |
| DONE (RO) | 1      | 0b            | Read Done<br>Set to 1b when the EEPROM read completes.<br>Set to 0b when the EEPROM read is not completed.<br>Writes by software are ignored. Reset by setting the START bit.                            |
| ADDR      | 15:2   | 0x0           | Read Address<br>This field is written by software along with <i>Start Read</i> to indicate the word to read.                                                                                             |
| DATA (RO) | 31:16  | X             | Read Data. Data returned from the EEPROM read.                                                                                                                                                           |

### 8.4.3 Flash Access - FLA (0x001C; R/W)

This register provides software direct access to the Flash. Software can control the Flash by successive writes to this register. Data and address information is clocked into the Flash by software toggling the *FL\_SCK* bit (bit 0) of this register with *FL\_CE* set to 0b. Data output from the Flash is latched into the *FL\_SO* bit (bit 3) of this register via the internal 125 MHz clock and can be accessed by software via reads of this register.

| Field        | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                              |
|--------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FL_SCK       | 0      | 0b            | Clock Input to the Flash<br>When <i>FL_GNT</i> is 1b, the <i>FL_SCK</i> out signal is mapped to this bit and provides the serial clock input to the Flash device. Software clocks the Flash memory via toggling this bit with successive writes.                                                                                                                         |
| FL_CE        | 1      | 1b            | Chip Select Input to the Flash<br>When <i>FL_GNT</i> is 1b, the <i>FL_CE</i> output signal is mapped to the chip select of the Flash device. Software enables the Flash by writing a 0b to this bit.                                                                                                                                                                     |
| FL_SI        | 2      | 1b            | Data Input to the Flash<br>When <i>FL_GNT</i> is 1b, the <i>FL_SI</i> output signal is mapped directly to this bit. Software provides data input to the Flash via writes to this bit.                                                                                                                                                                                    |
| FL_SO        | 3      | X             | Data Output Bit from the Flash<br>The <i>FL_SO</i> input signal is mapped directly to this bit in the register and contains the Flash memory serial data output. This bit is read only from the software perspective — writes to this bit have no effect.                                                                                                                |
| FL_REQ       | 4      | 0b            | Request Flash Access<br>The software must write a 1b to this bit to get direct Flash memory access. It has access when <i>FL_GNT</i> is 1b. When the software completes the access it must write a 0b.                                                                                                                                                                   |
| FL_GNT       | 5      | 0b            | Grant Flash Access<br>When this bit is 1b, the software can access the Flash memory using the <i>FL_SCK</i> , <i>FL_CE</i> , <i>FL_SI</i> , and <i>FL_SO</i> bits.                                                                                                                                                                                                       |
| FLA_add_size | 6      | 0b            | Flash Address Size<br>0b - Flash devices are accessed using 2 bytes of address.<br>1b - Flash devices (including 64 KB) are accessed using 3 bytes of the address.<br><b>Notes:</b><br>1. If this bit is set by one of the functions, it is also reflected in all other functions.<br>2. If value of <i>BARCTRL.FLSize</i> field is greater than 0x0, bit is read as 1b. |

| Field            | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                   |
|------------------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FLA_ABORT (RO)   | 7      | 0b            | Flash Access Aborted<br>Bit is set by HW when Flash access was aborted due to deadlock avoidance. When bit is set further Flash Bit Banging access from the function are blocked.<br><b>Note:</b> Bit is cleared by write 1b to the FLA.FLA_CLR_ERR bit.                                      |
| FLA_CLR_ERR (SC) | 8      | 0b            | Clear Flash Access Error<br>A write 1b to the FLA_CLR_ER bit clears the FLA.FLA_ABORT bit and enables further Bit Banging access to the Flash from the function.                                                                                                                              |
| Reserved         | 28:9   | 0x0           | Reserved<br>Write 0 ignore on read.                                                                                                                                                                                                                                                           |
| FL_BAR_WR (RO)   | 29     | 0b            | Flash Write via BAR in Progress<br>This bit is set to 1b while a write to the Flash memory is in progress or is pending as a result of a direct Memory access (not bit banging access). When this bit is clear (read as 0b) software can initiate a byte write operation to the Flash device. |
| FL_BUSY (RO)     | 30     | 0b            | Flash Busy<br>When set to 1b indicates that a Flash memory access is in progress.                                                                                                                                                                                                             |
| FL_ER (SC)       | 31     | 0b            | Flash Erase Command<br>When bit is set to 1b an erase command is sent to the Flash component only if the EEC.FWE field is 00b (Flash Erase). This bit is automatically cleared when flash erase has completed.                                                                                |

### 8.4.4 Flash Opcode - FLASHOP (0x103C; R/W)

This register enables the host or the firmware to define the op-code used in order to erase a sector of the flash or the complete flash. This register is reset only at power on assertion.

This register is common to all ports and manageability. Register should be programmed according to the parameters of the flash used.

**Note:** The default values fit to Atmel\* Serial Flash Memory devices.  
The flash device erase opcode default (0x62) matches older Atmel Flash Memory devices. For newer Atmel devices or for SST devices a value of 0x60 should be used.

| Field    | Bit(s) | Initial Value | Description                                                                                                                         |
|----------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------|
| DERASE   | 7:0    | 0x0062        | Flash Device Erase Instruction<br>The op-code for the Flash erase instruction.                                                      |
| SERASE   | 15:8   | 0x0052        | Flash Block Erase Instruction<br>The op-code for the Flash block erase instruction. Relevant only to Flash access by manageability. |
| Reserved | 31:16  | 0x0           | Reserved<br>Write 0 ignore on read.                                                                                                 |

### 8.4.5 EEPROM Auto Read Bus Control - EEARBC (0x1024; R/W)

In EEPROM-less implementations, this register is used to program the I350 the same way it should be programmed if an EEPROM was present. Refer to [Section 3.3.1.8.1](#) for details of this register usage.

This register is common to all functions and should be accessed only following access coordination with the other ports.

| Field        | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                  |

Firmware/software sets this bit for write access to registers loaded from EEPROM words in LAN3 section. Software should clear this bit to terminate the write transaction.                                           |
| Reserved     | 15     | 0b            | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                         |
| DATA         | 31:16  | 0x0           | Data written into the EEPROM auto read bus.                                                                                                                                                                                                                                  |

1. Not all EEPROM addresses are part of the auto read. By using this register software can write to the hardware registers that are configured during auto read only.
2. Host access via *EEARBC* can be done only when no EEPROM presence is detected. Management can access the internal registers via *EEARBC* also when EEPROM presence is detected and EEPROM load is done.

## 8.4.6 Management-EEPROM CSR I/F

The following registers are reserved for Firmware access to the EEPROM and are not writable by the host.

### 8.4.6.1 Management EEPROM Control Register - EEMNGCTL (0x1010; RW)

| Field                   | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDR                    | 14:0   | 0x0           | Address - This field is written by MNG along with Start Read or Start write to indicate the EEPROM word address to read or write.                                                                                                                                                                                                                                                                                   |
| START                   | 15     | 0b            | Start - Writing a 1b to this bit causes the EEPROM to start the read or write operation according to the write bit.<br><b>Note:</b> Bit is not cleared by Firmware reset.                                                                                                                                                                                                                                           |
| WRITE                   | 16     | 0b            | Write - This bit tells the EEPROM if the current operation is read or write:<br>0b = read<br>1b = write                                                                                                                                                                                                                                                                                                             |
| EEBUSY                  | 17     | 0b            | EEPROM Busy - This bit indicates that the EEPROM is busy processing an EEPROM transaction and EEPROM access will be delayed.                                                                                                                                                                                                                                                                                        |
| CFG_DONE 0 <sup>1</sup> | 18     | 0b            | Configuration cycle is done for port 0 - This bit indicates that configuration cycle (configuration of SerDes, PHY, PCIe and PLLs) is done for port 0. This bit is set to 1b to indicate configuration done, and cleared by hardware on any of the reset sources that causes initialization of the PHY.<br><b>Note:</b> Port 0 driver should not try to access the PHY for configuration before this bit is set.    |
| CFG_DONE 1 <sup>1</sup> | 19     | 0b            | Configuration cycle is done for port 1 - This bit indicates that configuration cycle (configuration of SerDes, PHY, PCIe and PLLs) is done for port 1. This bit is set to 1b to indicate configuration done, and cleared by hardware on any of the reset sources that cause initialization of the PHY.<br><b>Note:</b> Port 1 driver should not try to access the PHY for configuration before this bit is set.     |
| CFG_DONE 2 <sup>1</sup> | 20     | 0b            | Configuration cycle is done for port 2 - This bit indicates that the configuration cycle (configuration of SerDes, PHY, PCIe and PLLs) is done for port 2. This bit is set to 1b to indicate configuration done, and cleared by hardware on any of the reset sources that cause initialization of the PHY.<br><b>Note:</b> Port 2 driver should not try to access the PHY for configuration before this bit is set. |
| CFG_DONE 3 <sup>1</sup> | 21     | 0b            | Configuration cycle is done for port 3 - This bit indicates that the configuration cycle (configuration of SerDesPHY, PCIe and PLLs) is done for port 3. This bit is set to 1b to indicate configuration done, and cleared by hardware on any of the reset sources that cause initialization of the PHY.<br><b>Note:</b> Port 3 driver should not try to access the PHY for configuration before this bit is set.   |
| Reserved                | 28:22  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                |
| EEMNGCTL_CLR_ERR (SC)   | 29     | 0b            | Clear Timeout Error<br>A write 1b to the EEMNGCTL.EEMNGCTL_CLR_ERR bit clears the error reported in the EEMNGCTL.TIMEOUT bit.                                                                                                                                                                                                                                                                                       |
| TIMEOUT                 | 30     | 0b            | When bit is set to 1b indicates that a transaction timed out while trying to read the EEPROM status (Occurs when no EEPROM exists).<br><b>Notes:</b><br>1. To clear the bit Firmware should write 1b to the EEMNGCTL.EEMNGCTL_CLR_ERR bit.<br>2. Bit is not cleared by Firmware reset.                                                                                                                              |
| DONE                    | 31     | 1b            | Transaction Done - This bit is cleared after Start Write or Start Read bit is set by the MNG and is set back again when the EEPROM write or read transaction is done.<br><b>Note:</b> Bit is not cleared by Firmware reset.                                                                                                                                                                                         |

1. Bit relates to physical port. If LAN Function Swap (FACTPS.LAN Function Sel = 1) is done, Software should poll CFG\_DONE bit of original port to detect end of PHY configuration operation.

### 8.4.6.2 Management EEPROM Read/Write Data - EEMNGDATA (0x1014; RW)

| Field       | Bit(s) | Initial Value | Description                                      |
|-------------|--------|---------------|--------------------------------------------------|
| WRDATA      | 15:0   | 0x0           | Write Data<br>Data to be written to the EEPROM.  |
| RDDATA (RO) | 31:16  | –             | Read Data<br>Data returned from the EEPROM read. |

## 8.5 Flow Control Register Descriptions

### 8.5.1 Flow Control Address Low - FCAL (0x0028; RO)

Flow control packets are defined by 802.3X to be either a unique multicast address or the station address with the Ether Type field indicating PAUSE. The FCA registers provide the value hardware uses to compare incoming packets against, to determine that it should PAUSE its output.

The FCAL register contains the lower bits of the internal 48-bit Flow Control Ethernet address. All 32 bits are valid. Software can access the High and Low registers as a register pair if it can perform a 64-bit access to the PCIe bus. The complete flow control multicast address is: 0x01\_80\_C2\_00\_00\_01; where 0x01 is the first byte on the wire, 0x80 is the second, etc.

**Note:** Any packet matching the contents of {FCAH, FCAL, FCT} when CTRL.RFCE is set is acted on by the I350. Whether flow control packets are passed to the host (software) depends on the state of the RCTL.DPF bit and whether the packet matches any of the normal filters.

| Field | Bit(s) | Initial Value | Description              |
|-------|--------|---------------|--------------------------|
| FCAL  | 31:0   | 0x00C28001    | Flow Control Address Low |

### 8.5.2 Flow Control Address High - FCAH (0x002C; RO)

This register contains the upper bits of the 48-bit Flow Control Ethernet address. Only the lower 16 bits of this register have meaning. The complete Flow Control address is {FCAH, FCAL}.

The complete flow control multicast address is: 0x01\_80\_C2\_00\_00\_01; where 0x01 is the first byte on the wire, 0x80 is the second, etc.

| Field    | Bit(s) | Initial Value | Description                                                     |
|----------|--------|---------------|-----------------------------------------------------------------|
| FCAH     | 15:0   | 0x0100        | Flow Control Address High<br>Should be programmed with 0x01_00. |
| Reserved | 31:16  | 0x0           | Reserved<br>Write 0, ignore on read.                            |

### 8.5.3 Flow Control Type - FCT (0x0030; R/W)

This register contains the type field that hardware matches to recognize a flow control packet. Only the lower 16 bits of this register have meaning. This register should be programmed with 0x88\_08. The upper byte is first on the wire *FCT*[15:8].

| Field    | Bit(s) | Initial Value | Description                          |
|----------|--------|---------------|--------------------------------------|
| FCT      | 15:0   | 0x8808        | Flow Control Type                    |
| Reserved | 31:16  | 0x0           | Reserved<br>Write 0, ignore on read. |

### 8.5.4 Flow Control Transmit Timer Value - FCTTV (0x0170; R/W)

The 16-bit value in the *TTV* field is inserted into a transmitted frame (either XOFF frames or any PAUSE frame value in any software transmitted packets). It counts in units of slot time of 64 bytes. If software needs to send an XON frame, it must set *TTV* to 0 prior to initiating the PAUSE frame.

| Field    | Bit(s) | Initial Value | Description                          |
|----------|--------|---------------|--------------------------------------|
| TTV      | 15:0   | X             | Transmit Timer Value                 |
| Reserved | 31:16  | 0b            | Reserved<br>Write 0, ignore on read. |

### 8.5.5 Flow Control Receive Threshold Low - FCRTL0 (0x2160; R/W)

This register contains the receive threshold used to determine when to send an XON packet. The complete register reflects the threshold in units of bytes. The lower 4 bits must be programmed to 0b (16 byte granularity). Software must set *XONE* to enable the transmission of XON frames. Each time hardware crosses the receive-high threshold (becoming more full), and then crosses the receive-low threshold and *XONE* is enabled (1b), hardware transmits an XON frame.

When *XONE* is set, the *RTL* field should be programmed to at least 3b (at least 48 bytes).

Flow control reception/transmission are negotiated capabilities by the Auto-Negotiation process. When the I350 is manually configured, flow control operation is determined by the *CTRL.RFCE* and *CTRL.TFCE* bits.

| Field    | Bit(s) | Initial Value | Description                          |
|----------|--------|---------------|--------------------------------------|
| Reserved | 3:0    | 0000b         | Reserved<br>Write 0, ignore on read. |

|          |       |     |                                                                                                                                                                                                                                                                                                                                                                                 |
|----------|-------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RTL      | 16:4  | 0x0 | Receive Threshold Low.<br>FIFO low water mark for flow control transmission when Transmit Flow control is enabled ( <i>CTRL.TFCE</i> = 1b).<br>An XON packet is sent if the occupied space in the packet buffer is smaller or equal than this watermark.<br>This field is in 16 bytes granularity. This value should be set to at least 0x5 if transmit flow control is enabled |
| Reserved | 30:17 | 0x0 | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                            |
| XONE     | 31    | 0b  | XON Enable<br>0b = Disabled.<br>1b = Enabled.<br><br>If <i>FCRTL0.XONE</i> is 1, the minimum value allowed in <i>FCRTL0.RTL</i> is 3 (48 bytes).                                                                                                                                                                                                                                |

### 8.5.6 Flow Control Receive Threshold High - FCRTH0 (0x2168; R/W)

This register contains the receive threshold used to determine when to send an XOFF packet. The complete register reflects the threshold in units of bytes. This value must be at maximum 48 bytes less than the maximum number of bytes allocated to the Receive Packet Buffer (*IRPBS.RXPbsize*), and the lower 4 bits must be programmed to 0b (16 byte granularity). The value of *RTH* should also be bigger than *FCRTL0.RTL*. Each time the receive FIFO reaches the fullness indicated by *RTH*, hardware transmits a PAUSE frame if the transmission of flow control frames is enabled.

Flow control reception/transmission are negotiated capabilities by the Auto-Negotiation process. When the I350 is manually configured, flow control operation is determined by the *CTRL.RFCE* and *CTRL.TFCE* bits.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| GIO_COUNT_RESET | 29     | 0b            | Reset indication of PCIe statistical counters.                |
| GIO_COUNT_STOP  | 30     | 0b            | Stop indication of PCIe statistical counters.                 |
| GIO_COUNT_START | 31     | 0b            | Start indication of PCIe statistical counters.                |

## 8.6.3 PCIe Statistics Control #2 - GSCL\_2 (0x5B14; RW)

This register configures the events counted by the GSCN\_0, GSCN\_1, GSCN\_2 and GSCN\_3 counters.

**Note:**

| Field           | Bit(s) | Initial Value | Description                                |
|-----------------|--------|---------------|--------------------------------------------|
| GIO_EVENT_NUM_0 | 7:0    | 0x0           | Event type that counter 0 (GSCN_0) counts. |
| GIO_EVENT_NUM_1 | 15:8   | 0x0           | Event type that counter 1 (GSCN_1) counts. |
| GIO_EVENT_NUM_2 | 23:16  | 0x0           | Event type that counter 2 (GSCN_2) counts. |
| GIO_EVENT_NUM_3 | 31:24  | 0x0           | Event type that counter 3 (GSCN_3) counts. |

Table 8-9 lists the encoding of possible event types counted by GSCN\_0, GSCN\_1, GSCN\_2 and GSCN\_3.

**Table 8-9 PCIe Statistic Events Encoding**

| Transaction layer Events        | Event Mapping (Hex) | Description                                                                                                                                                                                                                                                                                        |
|---------------------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bad TLP from LL                 | 0x0                 | Each cycle, the counter increase in 1, if bad TLP is received (bad CRC, error reported by AL, misplaced special char, reset in middle of received TLP).                                                                                                                                            |
| Requests that reached timeout   | 0x10                | Number of requests that reached Time Out.                                                                                                                                                                                                                                                          |
| NACK DLLP received              | 0x20                | For each cycle, the counter increase by one, if a message was transmitted.                                                                                                                                                                                                                         |
| Replay happened in Retry-Buffer | 0x21                | Occurs when a replay happened due to timeout (not asserted when replay initiated due to NACK)                                                                                                                                                                                                      |
| Receive Error                   | 0x22                | Set when one of the following occurs:<br>1. Decoder error occurred during training in the PHY. It is reported only when training ends.<br>2. Decoder error occurred during link-up or till the end of the current packet (in case the link failed). This error is masked when entering/exiting EI. |
| Replay Roll-Over                | 0x23                | Occurs when replay was initiated for more than 3 times [threshold is configurable by the PHY CSRs]                                                                                                                                                                                                 |
| Re-Sending Packets              | 0x24                | Occurs when TLP is resend in case of completion timeout                                                                                                                                                                                                                                            |
| Surprise Link Down              | 0x25                | Occurs when link is unpredictably down (Not because of reset or DFT)                                                                                                                                                                                                                               |
| LTSSM in L0s in both Rx & Tx    | 0x30                | Occurs when LTSSM enters L0s state in both Tx & Rx                                                                                                                                                                                                                                                 |
| LTSSM in L0s in Rx              | 0x31                | Occurs when LTSSM enters L0s state in Rx                                                                                                                                                                                                                                                           |
| LTSSM in L0s in Tx              | 0x32                | Occurs when LTSSM enters L0s state in Tx                                                                                                                                                                                                                                                           |
| LTSSM in L1 active              | 0x33                | Occurs when LTSSM enters L1-Active state (Requested from Host side)                                                                                                                                                                                                                                |
| LTSSM in L1 SW                  | 0x34                | Occurs when LTSSM enters L1-Switch (Requested from Switch side)                                                                                                                                                                                                                                    |
| LTSSM in recovery               | 0x35                | Occurs when LTSSM enters Recovery state                                                                                                                                                                                                                                                            |

## 8.6.4 PCIe Statistic Control Register #5...#8 - GSCL\_5\_8 (0x5B90 + 4\*n[n=0...3]; RW)

These registers control the operation of the statistical counters GSCN\_0, GSCN\_1, GSCN\_2 and GSCN\_3 when operating Leaky Bucket mode:

- GSCL\_5 controls operation of GSCN\_0.
- GSCL\_6 controls operation of GSCN\_1.
- GSCL\_7 controls operation of GSCN\_2.

- GSCL\_8 controls operation of GSCN\_3.

| Field           | Bit(s) | Initial Value | Description                                                            |
|-----------------|--------|---------------|------------------------------------------------------------------------|
| LBC threshold n | 15:0   | 0x0           | Threshold for the Leaky Bucket Counter n                               |
| LBC timer n     | 31:16  | 0x0           | Time period between decrements of the value in Leaky Bucket Counter n. |

### 8.6.5 PCIe Counter #0 - GSCN\_0 (0x5B20; RC)

| Field | Bit(s) | Initial Value | Description                                                                                                                                                                                                      |
|-------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EVC   | 31:0   | 0x0           | Event Counter.<br>Type of event counted is defined by the <i>GSCL_2.GIO_EVENT_NUM_0</i> field.<br>Count value does not wrap around and remains stuck at the maximum value of 0xFF...F. Value is cleared by read. |

### 8.6.6 PCIe Counter #1 - GSCN\_1 (0x5B24; RC)

| Field | Bit(s) | Initial Value | Description                                                                                                                                                                                                      |
|-------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EVC   | 31:0   | 0x0           | Event Counter.<br>Type of event counted is defined by the <i>GSCL_2.GIO_EVENT_NUM_1</i> field.<br>Count value does not wrap around and remains stuck at the maximum value of 0xFF...F. Value is cleared by read. |

### 8.6.7 PCIe Counter #2 - GSCN\_2 (0x5B28; RC)

| Field | Bit(s) | Initial Value | Description                                                                                                                                                                                                      |
|-------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EVC   | 31:0   | 0x0           | Event Counter.<br>Type of event counted is defined by the <i>GSCL_2.GIO_EVENT_NUM_2</i> field.<br>Count value does not wrap around and remains stuck at the maximum value of 0xFF...F. Value is cleared by read. |

## 8.6.8 PCIe Counter #3 - GSCN\_3 (0x5B2C; RC)

| Field | Bit(s) | Initial Value | Description                                                                                                                                                                                               |
|-------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EVC   | 31:0   | 0x0           | Event Counter.<br>Type of event counted is defined by the GSCN_2.GIO_EVENT_NUM_3 field.<br>Count value does not wrap around and remains stuck at the maximum value of 0xFF...F. Value is cleared by read. |

## 8.6.9 Function Active and Power State to MNG - FACTPS (0x5B30; RO)

| Field             | Bit(s) | Initial Value | Description                                                                                                                                                                                           |
|-------------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Func0 Power State | 1:0    | 00b           | Power state indication of Function 0<br>00b → DR<br>01b → D0u<br>10b → D0a<br>11b → D3                                                                                                                |
| LAN0 Valid        | 2      | 0b            | LAN 0 Enable<br>When set to 0b, it indicates that the LAN 0 function is disabled. When the function is enabled, the bit is set to 1b.<br>The LAN 0 enable bit is set by the LAN0_DIS_N strapping pin. |
| Func0 Aux_En      | 3      | 0b            | Function 0 Auxiliary (AUX) Power PM Enable bit shadow from the configuration space.                                                                                                                   |
| Reserved          | 5:4    | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                 |
| Func1 Power State | 7:6    | 00b           | Power state indication of Function 1<br>00b → DR<br>01b → D0u<br>10b → D0a<br>11b → D3                                                                                                                |
| LAN1 Valid        | 8      | 0b            | LAN 1 Enable<br>When set to 0b, it indicates that the LAN 1 function is disabled. When the function is enabled, the bit is set to 1b.<br>The LAN 1 enable bit is set by the LAN1_DIS_N strapping pin. |
| Func1 Aux_En      | 9      | 0b            | Function 1 Auxiliary (AUX) Power PM Enable bit shadow from the configuration space.                                                                                                                   |
| Func2 Power State | 11:10  | 00b           | Power state indication of Function 2<br>00b → DR<br>01b → D0u<br>10b → D0a<br>11b → D3                                                                                                                |

## 8.7 Semaphore Registers

This section contains registers common to all ports used to coordinate between all functions. The usage of these registers is described in [Section 4.6.12](#)

## 8.7.1 Software Semaphore - SWSM (0x5B50; R/W)

| Field         | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SMBI (RS)     | 0      | 0x0           | <p>Software/Software Semaphore Bit</p> <p>This bit is set by hardware when this register is read by the device driver and cleared when the HOST driver writes a 0b to it.</p> <p>The first time this register is read, the value is 0b. In the next read the value is 1b (hardware mechanism). The value remains 1b until the software device driver clears it.</p> <p>This bit can be used as a semaphore between all the device's drivers in the I350.</p> <p>This bit is cleared on PCIe reset.</p>                                                                                                                                                                                                      |
| SWESMBI       | 1      | 0x0           | <p>Software/Firmware Semaphore bit</p> <p>This bit should be set only by the device driver (read only to firmware). The bit is not set if bit 0 in the FWSM register is set.</p> <p>The device driver should set this bit and then read it to verify that it was set. If it was set, it means that the device driver can access the SW_FW_SYNC register.</p> <p>The device driver should clear this bit after modifying the SW_FW_SYNC register.</p> <p>Notes:</p> <ul style="list-style-type: none"> <li>If Software takes ownership of the <i>SWSM.SWESMBI</i> bit for a duration longer than 100 mS, Firmware may take ownership of the bit.</li> <li>Hardware clears this bit on PCIe reset.</li> </ul> |
| Reserved      | 30:2   | 0x0           | <p>Reserved</p> <p>Write 0, ignore on read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| SWMB_CLR (SC) | 31     | 0b            | <p>Software Mailbox clear</p> <p>When bit is set to 1b, the <i>SWMBWR</i>, <i>SWMB0</i>, <i>SWMB1</i>, <i>SWMB2</i> and <i>SWMB3</i> Software Mailbox registers are reset.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## 8.7.2 Firmware Semaphore - FWSM (0x5B54; R/WS)

| Field <sup>1</sup> | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EEP_FW_Semaphore   | 0      | 0b            | <p>Software/Firmware Semaphore</p> <p>Firmware should set this bit to 1b before accessing the <i>SW_FW_SYNC</i> register. If the software is using the SWSM register and does not lock the <i>SW_FW_SYNC</i>, firmware is able to set this bit to 1b. Firmware should set this bit back to 0b after modifying the <i>SW_FW_SYNC</i> register.</p> <p>Note: If Software takes ownership of the <i>SWSM.SWESMBI</i> bit for a duration longer than 100 mS, Firmware may take ownership of the bit.</p> |
| FW_Mode            | 3:1    | 0x0           | <p>Firmware Mode</p> <p>Indicates the firmware mode as follows:</p> <p>000b = No MNG.</p> <p>001b = Reserved.</p> <p>010b = PT mode.</p> <p>011b = Reserved.</p> <p>100b = Reserved.</p> <p><b>Notes:</b> if FW_Mode = No MNG, proxy may still be supported if MANC.MPROXYE is set.</p>                                                                                                                                                                                                              |

| Factory MAC address restored | 31     | 0b            | This bit is set if the internal Firmware restored the factory MAC address at power up or if the factory MAC address and the regular MAC address were the same.<br>This bit is common to all ports. |

**Notes:**

1. This register should be written only by the manageability firmware. The device driver should only read this register.
2. Firmware ignores the EEPROM semaphore in operating system hung states.
3. Bits 15:0 are cleared on firmware reset.

### 8.7.3 Software–Firmware Synchronization - SW\_FW\_SYNC (0x5B5C; RWS)

This register is intended to synchronize between software and firmware. This register is common to all ports.

**Note:** If Software takes ownership of bits in the SW\_FW\_SYNC register for a duration longer than 1 Second, Firmware may take ownership of the bit.

| Field         | Bit(s) | Initial Value | Description                                                                 |
|---------------|--------|---------------|-----------------------------------------------------------------------------|
| SW_EEP_SM     | 0      | 0b            | When set to 1b, EEPROM access is owned by software                          |
| SW_PHY_SM0    | 1      | 0b            | When set to 1b, SerDes/PHY 0 access is owned by software                    |
| SW_PHY_SM1    | 2      | 0b            | When set to 1b, SerDes/PHY 1 access is owned by software                    |
| SW_MAC_CSR_SM | 3      | 0b            | When set to 1b, software owns access to shared CSRs                         |
| SW_FLASH_SM   | 4      | 0             | When set to 1b, software owns access to the flash.                          |
| SW_PHY_SM2    | 5      | 0b            | When set to 1b, SerDes/PHY 2 access is owned by software                    |
| SW_PHY_SM3    | 6      | 0b            | When set to 1b, SerDes/PHY 3 access is owned by software                    |
| SW_PWRTS_SM   | 7      | 0b            | When set to 1b Thermal Sensor Registers are owned by software driver.       |
| SW_MB_SM      | 8      | 0b            | When Set to 1b, SWMBWR mailbox write register, is owned by software driver. |
| Reserved      | 9      | 0b            | Reserved.<br>Write 0, ignore on read                                        |

| Field         | Bit(s) | Initial Value | Description                                                                                                                                     |
|---------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| SW_MNG_SM     | 10     | 0b            | When set to 1b Management Host interface is owned by port driver. Bit can be used by port driver when updating teaming or proxying information. |

| FW_EEP_SM     | 16     | 0b            | When set to 1b, EEPROM access is owned by firmware                                                                                              |
| FW_PHY_SM0    | 17     | 0b            | When set to 1b, PHY 0 access is owned by firmware                                                                                               |
| FW_PHY_SM1    | 18     | 0b            | When set to 1b, PHY 1 access is owned by Firmware                                                                                               |
| FW_MAC_CSR_SM | 19     | 0b            | When set to 1b, Firmware owns access to shared CSRs                                                                                             |
| FW_FLASH_SM   | 20     | 0             | When set to 1b, Firmware owns access to the flash.                                                                                              |
| FW_PHY_SM2    | 21     | 0b            | When set to 1b, PHY 2 access is owned by Firmware.                                                                                              |
| FW_PHY_SM3    | 22     | 0b            | When set to 1b, PHY 3 access is owned by Firmware.                                                                                              |
| FW_PWRTS_SM   | 23     | 0b            | When set to 1b Thermal Sensor Registers are owned by Firmware.                                                                                  |
| Reserved      | 31:24  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                            |

Reset conditions:

- The software-controlled bits 15:0 are reset as any other CSR on global resets, D3hot exit and Forced TCO. Software is expected to clear the bits on entry to D3 state.
- The Firmware controlled bits (bits 31:16) are reset on LAN\_PWR\_GOOD (power-up) and firmware reset.

## 8.7.4 Software Mailbox Write - SWMBWR (0x5B04; R/W)

| Field   | Bit(s) | Initial Value | Description                                                                                                                                                                                                                    |
|---------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mailbox | 31:0   | 0x0           | Message sent from driver to the other drivers. The interpretation of this field is defined by the drivers.<br><b>Note:</b> This register is reset by power on reset and by a write 1b to the <code>SWSM.SWMB_CLR</code> field. |

## 8.7.5 Software Mailbox 0 - SWMB0 (0x5B08; RO)

| Field   | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                           |
|---------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mailbox | 31:0   | 0x0           | Message sent from the driver of port 0 via write to the <code>SWMBWR</code> register. The interpretation of this field is defined by the drivers.<br><b>Note:</b> This register is reset by power on reset and by a write 1b to the <code>SWSM.SWMB_CLR</code> field. |

## 8.7.6 Software Mailbox 1 - SWMB1 (0x5B0C; RO)

| Field   | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                               |
