Software should issue a software (CTRL.RST) reset to enable PCIe activity on all ports. |
| Reserved | 31:6   | 0x0   | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                 |

## 8.8.2 PCIe Interrupt Enable - PIENA (0x5B8C; R/W)

| Field    | Bit(s) | Init. | Description                                                           |
|----------|--------|-------|-----------------------------------------------------------------------|
| CA       | 0      | 0b    | When set to 1 the PCI Completion Abort interrupt is enabled.          |
| UA       | 1      | 0b    | When set to 1 the Unsupported IO address interrupt is enabled.        |
| BE       | 2      | 0b    | When set to 1 the Wrong Byte-Enable interrupt is enabled.             |
| TO       | 3      | 0b    | When set to 1 the PCI Timeout interrupt is enabled.                   |
| BMEF     | 4      | 0b    | When set to 1 the Bus Master Enable interrupt is enabled.             |
| ABR      | 5      | 0b    | When set to 1 the PCI completion abort received interrupt is enabled. |
| Reserved | 31:6   | 0x0   | Reserved<br>Write 0, ignore on read.                                  |

## 8.8.3 Extended Interrupt Cause - EICR (0x1580; RC/W1C)

This register contains the frequent interrupt conditions for the I350. Each time an interrupt causing event occurs, the corresponding interrupt bit is set in this register. An interrupt is generated each time one of the bits in this register is set and the corresponding interrupt is enabled via the Interrupt Mask Set/Read register. The interrupt might be delayed by the selected Interrupt Throttling register.

Note that the software device driver cannot determine from the RxTxQ bits what was the cause of the interrupt. The possible causes for asserting these bits are:

- Receive Descriptor Write Back, Receive Descriptor Minimum Threshold hit, low latency interrupt for Rx, Transmit Descriptor Write Back.

Writing a 1b to any bit in the register clears that bit. Writing a 0b to any bit has no effect on that bit.

Register bits are cleared on register read if GPIE.Multiple\_MSIX = 0

Auto clear can be enabled for any or all of the bits in this register.

**Table 8-11 EICR Register Bit Description - non MSI-X mode (GPIE.Multiple\_MSIX = 0)**

| Field       | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                   |

| Other Cause | 31     | 0b            | Interrupt Cause Active<br>Activated when any bit in the ICR register is set.                                                                                                                                                                                                                                                                                                  |

**Note:** Bits are not reset by Device Reset (*CTRL.DEV\_RST*).

**Table 8-12 EICR Register Bit Description - MSI-X mode (GPIE.Multiple\_MSIX = 1)**

| Field    | Bit(s) | Initial Value | Description                                                                                                                    |
|----------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| MSIX     | 24:0   | 0x0           | Indicates an interrupt cause mapped to MSI-X vectors 24:0<br>Note: Bits are not reset by Device Reset ( <i>CTRL.DEV_RST</i> ). |
| Reserved | 31:25  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                           |

**Note:** In IOV mode bit 0 of this vector is available for the PF function, additional bits may be allocated per VF MSI-X vector usage.

## 8.8.4 Extended Interrupt Cause Set - EICS (0x1520; WO)

Software uses this register to set an interrupt condition. Any bit written with a 1b sets the corresponding bit in the Extended Interrupt Cause Read register. An interrupt is then generated if one of the bits in this register is set and the corresponding interrupt is enabled via the Extended Interrupt Mask Set/Read register. Bits written with 0b are unchanged.

**Table 8-13 EICS Register Bit Description - non MSI-X mode (GPIE.Multiple\_MSIX = 0)**

| Field     | Bit(s) | Initial Value | Description                                                |
|-----------|--------|---------------|------------------------------------------------------------|
| RxTxQ     | 7:0    | 0x0           | Sets to corresponding EICR RxTxQ interrupt condition.      |
| Reserved  | 29:8   | 0x0           | Reserved<br>Write 0, ignore on read.                       |
| TCP Timer | 30     | 0b            | Sets the corresponding EICR TCP Timer interrupt condition. |
| Reserved  | 31     | 0b            | Reserved<br>Write 0, ignore on read.                       |

**Note:** In order to set bit 31 of the *EICR* (*Other Causes*), the *ICS* and *IMS* registers should be used in order to enable one of the legacy causes.

**Table 8-14 EICS Register Bit Description - MSI-X mode (GPIE.Multiple\_MSIX = 1)**

| Field    | Bit(s) | Initial Value | Description                                                  |
|----------|--------|---------------|--------------------------------------------------------------|
| MSIX     | 24:0   | 0x0           | Sets the corresponding <i>EICR</i> bit of MSI-X vectors 24:0 |
| Reserved | 31:25  | 0x0           | Reserved<br>Write 0, ignore on read.                         |

## 8.8.5 Extended Interrupt Mask Set/Read - EIMS (0x1524; RWS)

Reading of this register returns which bits have an interrupt mask set. An interrupt in *EICR* is enabled if its corresponding mask bit is set to 1b and disabled if its corresponding mask bit is set to 0b. A PCI interrupt is generated each time one of the bits in this register is set and the corresponding interrupt condition occurs (subject to throttling). The occurrence of an interrupt condition is reflected by having a bit set in the Extended Interrupt Cause Read register.

An interrupt might be enabled by writing a 1b to the corresponding mask bit location (as defined in the *EICR* register) in this register. Any bits written with a 0b are unchanged. As a result, if software needs to disable an interrupt condition that had been previously enabled, it must write to the *Extended Interrupt Mask Clear* register rather than writing a 0b to a bit in this register.

**Table 8-15 EIMS Register Bit Description - non MSI-X mode (GPIE.Multiple\_MSIX = 0)**

| Field       | Bit(s) | Initial Value | Description                                                                     |
|-------------|--------|---------------|---------------------------------------------------------------------------------|
| RxTxQ       | 7:0    | 0x0           | Set Mask bit for the corresponding <i>EICR</i> RxTxQ interrupt.                 |
| Reserved    | 29:8   | 0x0           | Reserved<br>Write 0, ignore on read.                                            |
| TCP Timer   | 30     | 0b            | Set Mask bit for the corresponding <i>EICR</i> TCP timer interrupt condition.   |
| Other Cause | 31     | 1b            | Set Mask bit for the corresponding <i>EICR</i> other cause interrupt condition. |

**Note:** Bits are not reset by Device Reset (*CTRL.DEV\_RST*).

**Table 8-16 EIMS Register Bit Description - MSI-X mode (GPIE.Multiple\_MSIX = 1)**

| Field    | Bit(s) | Initial Value | Description                                                                                                                                    |
|----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|

## 8.8.6 Extended Interrupt Mask Clear - EIMC (0x1528; WO)

This register provides software a way to disable certain or all interrupts. Software disables a given interrupt by writing a 1b to the corresponding bit in this register.

On interrupt handling, the software device driver should set all the bits in this register related to the current interrupt request even though the interrupt was triggered by part of the causes that were allocated to this vector.

Interrupts are presented to the bus interface only when the mask bit is set to 1b and the cause bit is set to 1b. The status of the mask bit is reflected in the Extended Interrupt Mask Set/Read register and the status of the cause bit is reflected in the Interrupt Cause Read register.

Software blocks interrupts by clearing the corresponding mask bit. This is accomplished by writing a 1b to the corresponding bit location (as defined in the *EICR* register) of that interrupt in this register. Bits written with 0b are unchanged (their mask status does not change).

**Table 8-17 EIMC Register Bit Description - non MSI-X mode (GPIE.Multiple\_MSIX = 0)**

| Field       | Bit(s) | Initial Value | Description                                                             |
|-------------|--------|---------------|-------------------------------------------------------------------------|
| RxTxQ       | 7:0    | 0x0           | Clear Mask bit for the corresponding <i>EICR</i> RxTxQ interrupt.       |
| Reserved    | 29:8   | 0x0           | Reserved<br>Write 0, ignore on read.                                    |
| TCP Timer   | 30     | 0b            | Clear Mask bit for the corresponding <i>EICR</i> TCP timer interrupt.   |
| Other Cause | 31     | 1b            | Clear Mask bit for the corresponding <i>EICR</i> other cause interrupt. |

| Field    | Bit(s) | Initial Value | Description                                                                |
|----------|--------|---------------|----------------------------------------------------------------------------|
| MSIX     | 24:0   | 0x0           | clear Mask bit for the corresponding <i>EICR</i> bit of MSI-X vectors 24:0 |
| Reserved | 31:25  | 0x0           | Reserved<br>Write 0, ignore on read.                                       |

## 8.8.7 Extended Interrupt Auto Clear - EIAC (0x152C; R/W)

This register is mapped like the *EICS*, *EIMS*, and *EIMC* registers, with each bit mapped to the corresponding MSI-X vector.

This register is relevant to MSI-X mode only, where read-to-clear can not be used, as it might erase causes tied to other vectors. If any bits are set in *EIAC*, the *EICR* register should not be read. Bits without auto clear set, need to be cleared with write-to-clear.

**Note:** *EICR* bits that have auto clear set are cleared by the internal emission of the corresponding MSI-X message even if this vector is disabled by the operating system.

The MSI-X message can be delayed by *EITR* moderation from the time the *EICR* bit is activated.

**Table 8-19 EIAC Register Bit Description - MSI-X mode (GPIE.Multiple\_MSIX = 1)**

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                      |
|----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSIX     | 24:0   | 0x0           | Auto clear bit for the corresponding <i>EICR</i> bit of MSI-X vectors 24:0.<br>Notes: <ul style="list-style-type: none"> <li>Bits are not reset by Device Reset (<i>CTRL.DEV_RST</i>).</li> <li>When <i>GPIE.Multiple_MSIX</i> = 0 (Non MSI-X mode) bits 8 and 9 are read only and should be ignored.</li> </ul> |
| Reserved | 31:25  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                             |

## 8.8.8 Extended Interrupt Auto Mask Enable - EIAM (0x1530; R/W)

Each bit in this register enables clearing of the corresponding bit in *EIMS* register following read- or write-to-clear to *EICR* or setting of the corresponding bit in *EIMS* following a write-to-set to *EICS*.

In MSI-X mode, this register controls which of the bits in the *EIMS* register to clear upon interrupt generation if enabled via the *GPIE.EIAME* bit.

**Note:** When operating in MSI mode than setting any bit in the *EIAM* register will cause clearing of all bits in the *EIMS* register and masking of all interrupts following generation of a MSI interrupt.

**Table 8-20 EIAM Register Bit Description - non MSI-X mode (GPIE.Multiple\_MSIX = 0)**

| Field       | Bit(s) | Initial Value | Description                                                                      |
|-------------|--------|---------------|----------------------------------------------------------------------------------|
| RxTxQ       | 7:0    | 0x0           | Auto Mask bit for the corresponding <i>EICR RxTxQ</i> interrupt.                 |
| Reserved    | 29:8   | 0x0           | Reserved<br>Write 0, ignore on read.                                             |
| TCP Timer   | 30     | 0b            | Auto mask bit for the corresponding <i>EICR TCP timer</i> interrupt condition.   |
| Other Cause | 31     | 0b            | Auto mask bit for the corresponding <i>EICR other cause</i> interrupt condition. |

**Note:** Bits are not reset by Device Reset (*CTRL.DEV\_RST*).

**Table 8-21 EIAM Register Bit Description - MSI-X mode (GPIE.Multiple\_MSIX = 1)**

| Field    | Bit(s) | Initial Value | Description                                                                                                                                     |
|----------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| MSIX     | 24:0   | 0x0           | Auto Mask bit for the corresponding <i>EICR</i> bit of MSI-X vectors 24:0.<br>Note: Bits are not reset by Device Reset ( <i>CTRL.DEV_RST</i> ). |
| Reserved | 31:25  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                            |

## 8.8.9 Interrupt Cause Read Register - ICR (0x1500; RC/W1C)

This register contains the interrupt conditions for the I350 that are not present directly in the EICR. Each time an ICR interrupt causing event occurs, the corresponding interrupt bit is set in this register. The *EICR.Other* bit reflects the setting of interrupt causes from *ICR* as masked by the Interrupt Mask Set/Read register. Each time all un-masked causes in *ICR* are cleared, the *EICR.Other* bit is also cleared.

*ICR* bits are cleared on register read. Clear-on-read can be enabled/disabled through a general configuration register bit. Refer to [Section 7.3.3](#) for additional information.

Auto clear is not available for the bits in this register.

In order to prevent unwanted *LSC* (*Link Status Change*) interrupts during initialization, software should disable this interrupt until the end of initialization.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                            |

## 8.8.10 Interrupt Cause Set Register - ICS (0x1504; WO)

Software uses this register to set an interrupt condition. Any bit written with a 1b sets the corresponding interrupt. This results in the corresponding bit being set in the Interrupt Cause Read Register (refer to [Section 8.8.9](#)). A PCIe interrupt is generated if one of the bits in this register is set and the corresponding interrupt is enabled through the Interrupt Mask Set/Read Register (refer to [Section 8.8.11](#)). Bits written with 0b are unchanged. Refer to [Section 7.3.3](#) for additional information.

| Field         | Bit(s) | Initial Value | Description                                                                                                                    |
|---------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| TXDW          | 0      | 0b            | Sets the Transmit Descriptor Written Back Interrupt.                                                                           |

### 8.8.11 Interrupt Mask Set/Read Register - IMS (0x1508; R/W)

Reading this register returns bits that have an interrupt mask set. An interrupt is enabled if its corresponding mask bit is set to 1b and disabled if its corresponding mask bit is set to 0b. A PCIe interrupt is generated each time one of the bits in this register is set and the corresponding interrupt condition occurs. The occurrence of an interrupt condition is reflected by having a bit set in the Interrupt Cause Read Register (refer to [Section 8.8.9](#)).

A particular interrupt can be enabled by writing a 1b to the corresponding mask bit in this register. Any bits written with a 0b are unchanged. As a result, if software desires to disable a particular interrupt condition that had been previously enabled, it must write to the Interrupt Mask Clear Register (refer to [Section 8.8.12](#)) rather than writing a 0b to a bit in this register. Refer to [Section 7.3.3](#) for additional information.

| Field         | Bit(s) | Initial Value | Description                                                                 |

## 8.8.12 Interrupt Mask Clear Register - IMC (0x150C; WO)

Software uses this register to disable an interrupt. Interrupts are presented to the bus interface only when the mask bit is set to 1b and the cause bit set to 1b. The status of the mask bit is reflected in the Interrupt Mask Set/Read Register (refer to [Section 8.8.11](#)), and the status of the cause bit is reflected in the Interrupt Cause Read Register (refer to [Section 8.8.9](#)). Reading this register returns the value of the IMS register.

Software blocks interrupts by clearing the corresponding mask bit. This is accomplished by writing a 1b to the corresponding bit in this register. Bits written with 0b are unchanged (their mask status does not change).

Software device driver should set all the bits in this register related to the current interrupt request when handling interrupts, even though the interrupt was triggered by part of the causes that were allocated to this vector. Refer to [Section 7.3.3](#) for additional information.

| Field     | Bit(s) | Initial Value | Description                                                             |
|-----------|--------|---------------|-------------------------------------------------------------------------|
| TXDW      | 0      | 0b            | Clears the mask for Transmit Descriptor Written Back Interrupt.         |
| Reserved  | 1      | 0b            | Reserved<br>Write 0, ignore on read.                                    |

### 8.8.13 Interrupt Acknowledge Auto Mask Register - IAM (0x1510; R/W)

| Field     | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IAM_VALUE | 30:0   | 0b            | An <i>ICR</i> read or write will have the side effect of writing the contents of this register to the <i>IMC</i> register. If <i>GPIE.NSICR</i> = 0, then the copy of this register to the <i>IMC</i> register will occur only if at least one bit is set in the <i>IMS</i> register and there is a true interrupt as reflected in the <i>ICR.INTA</i> bit. Refer to <a href="#">Section 7.3.3</a> for additional information.<br><b>Note:</b> Bit 30 of this register is not reset by Device Reset ( <i>CTRL.DEV_RST</i> ). |
| Reserved  | 31     | 0b            | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 8.8.14 Interrupt Throttle - EITR (0x1680 + 4\*n [n = 0...24]; R/W)

Each *EITR* is responsible for an interrupt cause (RxTxQ, TCP timer and Other Cause). The allocation of *EITR*-to-interrupt cause is through the *IVAR* registers.

Software uses this register to pace (or even out) the delivery of interrupts to the host processor. This register provides a guaranteed inter-interrupt delay between interrupts asserted by the I350, regardless of network traffic conditions. To independently validate configuration settings, software can use the following algorithm to convert the inter-interrupt interval value to the common interrupts/sec. performance metric:

$$\text{interrupts/sec} = (1 * 10^{-6} \text{sec} \times \text{interval})^{-1}$$

A counter counts in units of  $1 \times 10^{-6}$  sec. After counting “interval” number of units, an interrupt is sent to the software. The above equation gives the number of interrupts per second. The equation below time in seconds between consecutive interrupts.

For example, if the interval is programmed to 125 (decimal), the I350 guarantees the processor does not receive an interrupt for 125  $\mu$ s from the last interrupt. The maximum observable interrupt rate from the I350 should never exceed 8000 interrupts/sec.

Inversely, inter-interrupt interval value can be calculated as:

$$\text{inter-interrupt interval} = (1 * 10^{-6} \text{sec} \times \text{interrupt/sec})^{-1}$$

The optimal performance setting for this register is very system and configuration specific. An initial suggested range is 2 to 175 (0x02 to 0xAF).

**Note:** Setting EITR to a non zero value can cause an interrupt cause Rx/Tx statistics miscount.

| Field                    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Interval                 | 14:2   | 0x0           | Minimum inter-interrupt interval. The interval is specified in 1 $\mu$ s increments. A zero disables interrupt throttling logic.                                                                                                                                                                                                                                                                                                                                   |
| LLI_EN                   | 15     | 0b            | LLI moderation enable.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| LL Counter (RWS)         | 20:16  | 0x0           | Reflects the current credits for that EITR for LL interrupts. If the CNT_INGR is not set this counter can be directly written by software at any time to alter the throttles performance                                                                                                                                                                                                                                                                           |
| Moderation Counter (RWS) | 30:21  | 0x0           | Down counter, exposes only the 10 most significant bits of the real 12-bit counter. Loaded with Interval value whenever the associated interrupt is signaled. Counts down to 0 and stops. The associated interrupt is signaled whenever this counter is zero and an associated (via the Interrupt Select register) EICR bit is set.<br>If the CNT_INGR is not set this counter can be directly written by software at any time to alter the throttles performance. |
| CNT_INGR (WO)            | 31     | 0b            | When set the hardware does not override the counters fields (ITR counter and LLI credit counter), so they keep their previous value.<br>Relevant for the current write only and is always read as zero                                                                                                                                                                                                                                                             |

**Note:** EITR register and interrupt mechanism is not reset by Device Reset (CTRL.DEV\_RST). Occurrence of Device Reset interrupt causes immediate generation of all pending interrupts.

## 8.8.15 Interrupt Vector Allocation Registers - IVAR (0x1700 + 4\*n [n=0...3]; RW)

These registers have three modes of operation:

1. In MSI-X mode these registers define the allocation of the different interrupt causes as defined in [Table 7-48](#) to one of the MSI-X vectors. Each *INT\_Alloc[i]* (i=0...15) field is a byte indexing an entry in the MSI-X Table Structure and MSI-X PBA Structure.
2. In non MSI-X mode these registers define the allocation of the Rx and Tx queues interrupt causes to one of the RxTxQ bits in the EICR register. Each *INT\_Alloc[i]* (i=0...15) field is a byte indexing the appropriate RxTxQ bit as defined in [Table 7-47](#).
3. In SR-IOV mode MSI-X mode is always activated. These registers define the allocation of the different interrupt causes as defined in [Table 7-48](#) to one of the MSI-X vectors. Each *INT\_Alloc[i]*

( $i=0\ldots15$ ) field is a byte indexing an entry in the MSI-X Table Structure and MSI-X PBA Structure. Any *INT\_Alloc[i]* field that is allocated to a VF is Read only (RO), while any *INT\_Alloc[i]* fields allocated to the PF are Read/Write (R/W). Fields allocated to the VF can be accessed by the PF using the VF address space (See *VTIVAR* addresses under the Physical Address Base column in [Section 8.27.3](#)).

Entries are mapped as follows:

- Queues RX0, TX0, RX1, TX1 are mapped in *IVAR[0]* Register.
- Queues RX2, TX2, RX3, TX3 are mapped in *IVAR[1]* Register.
- Queues RX4, TX4, RX5, TX5 are mapped in *IVAR[2]* Register.
- Queues RX6, TX6, RX7, TX7 are mapped in *IVAR[3]* Register.

| Field            | Bit(s) | Initial Value | Description                                                                                                                                                                                           |
|------------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INT_Alloc[0]     | 4:0    | 0x0           | Defines the MSI-X vector assigned to the interrupt cause associated with this entry, as defined in <a href="#">Table 7-48</a> . Valid values are 0 to 24 for MSI-X mode and 0 to 7 in non MSI-X mode. |
| Reserved         | 6:5    | 0x0           | Reserved<br>Write 0 ignore on read.                                                                                                                                                                   |
| INT_Alloc_val[0] | 7      | 0b            | Valid bit for INT_Alloc[0]                                                                                                                                                                            |
| INT_Alloc[1]     | 12:8   | 0x0           | Defines the MSI-X vector assigned to the interrupt cause associated with this entry, as defined in <a href="#">Table 7-48</a> . Valid values are 0 to 24 for MSI-X mode and 0 to 7 in non MSI-X mode. |
| Reserved         | 14:13  | 0x0           | Reserved<br>Write 0 ignore on read                                                                                                                                                                    |
| INT_Alloc_val[1] | 15     | 0b            | Valid bit for INT_Alloc[1]                                                                                                                                                                            |
| INT_Alloc[2]     | 20:16  | 0x0           | Defines the MSI-X vector assigned to the interrupt cause associated with this entry, as defined in <a href="#">Table 7-48</a> . Valid values are 0 to 24 for MSI-X mode and 0 to 7 in non MSI-X mode. |
| Reserved         | 22:21  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                  |
| INT_Alloc_val[2] | 23     | 0b            | Valid bit for INT_Alloc[2]                                                                                                                                                                            |
| INT_Alloc[3]     | 28:24  | 0x0           | Defines the MSI-X vector assigned to the interrupt cause associated with this entry, as defined in <a href="#">Table 7-48</a> . Valid values are 0 to 24 for MSI-X mode and 0 to 7 in non MSI-X mode. |
| Reserved         | 30:29  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                  |
| INT_Alloc_val[3] | 31     | 0b            | Valid bit for INT_Alloc[3]                                                                                                                                                                            |

**Note:** If invalid values are written to the INT\_Alloc fields the result is unexpected.

## 8.8.16 Interrupt Vector Allocation Registers - MISC IVAR\_MISC (0x1740; RW)

This register is used only in MSI-X mode. This register defines the allocation of the *Other Cause* and *TCP Timer* interrupts to one of the MSI-X vectors.

| Field             | Bit(s) | Initial Value | Description                                                                                   |
|-------------------|--------|---------------|-----------------------------------------------------------------------------------------------|
| INT_Alloc[16]     | 4:0    | 0x0           | Defines the MSI-X vector assigned to the TCP timer interrupt cause. Valid values are 0 to 24. |
| Reserved          | 6:5    | 0x0           | Reserved<br>Write 0, ignore on read.                                                          |
| INT_Alloc_val[16] | 7      | 0b            | Valid bit for INT_Alloc[16]                                                                   |
| INT_Alloc[17]     | 12:8   | 0x0           | Defines the MSI-X vector assigned to the "Other Cause" interrupt. Valid values are 0 to 24.   |
| Reserved          | 14:13  | 0b            | Reserved<br>Write 0, ignore on read.                                                          |
| INT_Alloc_val[17] | 15     | 0b            | Valid bit for INT_Alloc[17]                                                                   |
| Reserved          | 31:16  | 0x0           | Reserved<br>Write 0, ignore on read.                                                          |

## 8.8.17 General Purpose Interrupt Enable - GPIE (0x1514; RW)

| Field         | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                           |
|---------------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NSICR         | 0      | 0b            | Non Selective Interrupt clear on read: When set, every read of <i>ICR</i> clears it. When this bit is cleared, an <i>ICR</i> read causes it to be cleared only if an actual interrupt was asserted or <i>IMS</i> = 0x0.<br>Refer to <a href="#">Section 7.3.3</a> for additional information.                                                                         |
| Reserved      | 3:1    | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                  |
| Multiple MSIX | 4      | 0b            | 0 = on-MSI mode, or MSI-X with single vector, <i>IVAR</i> maps Rx/Tx causes, to 8 <i>EICR</i> bits, but <i>MSIX</i> [0] is asserted for all.<br>1 = MSIX mode, <i>IVAR</i> maps Rx/Tx causes, TCP Timer and "Other Cause" interrupts to 25 MSI-x vectors reflected in 25 <i>EICR</i> bits.<br><b>Note:</b> When set, the <i>EICR</i> register is not cleared on read. |
| Reserved      | 6:5    | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                  |
| LL Interval   | 11:7   | 0x0           | Low latency credits increment rate. The interval is specified in 4 $\mu$ s increments. A value of 0x0 disables moderation of LLI for all interrupt vectors.                                                                                                                                                                                                           |
| Reserved      | 29:12  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                  |

| Field       | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EIAME       | 30     | 0b            | Extended Interrupt Auto Mask enable: When set (usually in MSI-X mode); upon firing of a MSI-X message, if bits in <i>EIAM</i> register associated with this message are set then the corresponding bits in the <i>EIMS</i> register will be cleared. Otherwise, <i>EIAM</i> is used only upon read or write of EICR/EICS registers.<br><b>Note:</b> When bit is set in MSI mode than setting of any bit in the <i>EIAM</i> register will cause clearing of all bits in the <i>EIMS</i> register and masking of all interrupts following generation of a MSI interrupt. |
| PBA_support | 31     | 0b            | PBA Support: When set, setting one of the extended interrupts masks via <i>EIMS</i> causes the PBA bit of the associated MSI-X vector to be cleared. Otherwise, the I350 behaves in a way that supports legacy INT-x interrupts.<br><b>Note:</b> Should be cleared when working in INT-x or MSI mode and set in MSI-X mode.                                                                                                                                                                                                                                            |

## 8.9 MSI-X Table Register Descriptions

These registers are used to configure the MSI-X mechanism. The *message address* and *message upper address* registers sets the address for each of the vectors. The message register sets the data sent to the relevant address. The vector control registers are used to enable specific vectors.

The pending bit array register indicates which vectors have pending interrupts. The structure is listed in Table 8-22.

**Table 8-22 MSI-X Table Structure**

| DWORD3<br>MSIXTVCTRL | DWORD2<br>MSIXTMSG | DWORD1<br>MSIXTUADD | DWORD0<br>MSIXTADD | Entry<br>Number | BAR 3 - Offset   |
|----------------------|--------------------|---------------------|--------------------|-----------------|------------------|
| Vector Control       | Msg Data           | Msg Upper Addr.     | Msg Addr           | Entry 0         | Base (0x0000)    |
| Vector Control       | Msg Data           | Msg Upper Addr      | Msg Addr           | Entry 1         | Base + 1*16      |
| Vector Control       | Msg Data           | Msg Upper Addr      | Msg Addr           | Entry 2         | Base + 2*16      |
| ...                  | ...                | ...                 | ...                | ...             | ...              |
| Vector Control       | Msg Data           | Msg Upper Addr      | Msg Addr           | Entry (N-1)     | Base + (N-1) *16 |

**Note:** N = 25.

**Table 8-23 MSI-X PBA Structure**

| MSIXPBA[63:0]                              | QWORD<br>Number     | BAR 3 - Offset          |
|--------------------------------------------|---------------------|-------------------------|
| Pending Bits 0 through 63                  | QWORD0              | Base (0x2000)           |
| Pending Bits 64 through 127                | QWORD1              | Base+1*8                |
| ...                                        | ...                 | ...                     |
| Pending Bits ((N-1) div 64)*64 through N-1 | QWORD((N-1) div 64) | BASE + ((N-1) div 64)*8 |

**Note:** N = 25. As a result, only QWORD0 is implemented.

### 8.9.1 MSI-X Table Entry Lower Address - MSIXTADD (BAR3: 0x0000 + 0x10\*n [n=0...24]; R/W)

| Field                    | Bit(s) | Initial Value | Description                                                                                                                                                                                                  |
|--------------------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Message Address LSB (RO) | 1:0    | 0x0           | For proper DWORD alignment, software must always write 0b's to these two bits. Otherwise, the result is undefined.                                                                                           |
| Message Address          | 31:2   | 0x0           | System-Specific Message Lower Address<br>For MSI-X messages, the contents of this field from an MSI-X table entry specifies the lower portion of the DWORD-aligned address for the memory write transaction. |

### 8.9.2 MSI-X Table Entry Upper Address - MSIXTUADD (BAR3: 0x0004 + 0x10\*n [n=0...24]; R/W)

| Field           | Bit(s) | Initial Value | Description                           |
|-----------------|--------|---------------|---------------------------------------|
| Message Address | 31:0   | 0x0           | System-Specific Message Upper Address |

### 8.9.3 MSI-X Table Entry Message - MSIXTMSG (BAR3: 0x0008 + 0x10\*n [n=0...24]; R/W)

| Field        | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                        |
|--------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Message Data | 31:0   | 0x0           | System-Specific Message Data<br>For MSI-X messages, the contents of this field from an MSI-X table entry specifies the data written during the memory write transaction.<br>In contrast to message data used for MSI messages, the low-order message data bits in MSI-X messages are not modified by the function. |

### 8.9.4 MSI-X Table Entry Vector Control - MSIXTVCTRL (BAR3: 0x000C + 0x10\*n [n=0...24]; R/W)

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                  |
|----------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mask     | 0      | 1b            | When this bit is set, the function is prohibited from sending a message using this MSI-X table entry. However, any other MSI-X table entries programmed with the same vector are still capable of sending an equivalent message unless they are also masked. |
| Reserved | 31:1   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                         |

### 8.9.5 MSIXPBA Bit Description – MSIXPBA (BAR3: 0x2000; RO)

| Field        | Bit(s) | Initial Value | Description                                                                                                                                                                        |
|--------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pending Bits | 24:0   | 0x0           | For each pending bit that is set, the function has a pending message for the associated MSI-X Table entry.<br>Pending bits that have no associated MSI-X table entry are reserved. |
| Reserved     | 31:25  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                               |

### 8.9.6 MSI-X PBA Clear – PBACL (0x5B68; R/W1C)

| Field     | Bit(s) | Initial Value | Description                                                                                                                                                                                        |
|-----------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PENBITCLR | 24:0   | 0x0           | MSI-X Pending bits Clear<br>Writing a 1b to any bit clears the corresponding MSIXPBA bit; writing a 0b has no effect.<br><b>Note:</b> Bits are set for a single PCIe clock cycle and then cleared. |
| Reserved  | 31:25  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                               |

## 8.10 Receive Register Descriptions

### 8.10.1 Receive Control Register - RCTL (0x0100; R/W)

This register controls all the I350 receiver functions.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Reserved | 0      | 0b            | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| RXEN     | 1      | 0b            | Receiver Enable<br>The receiver is enabled when this bit is set to 1b. Writing this bit to 0b stops reception after receipt of any in progress packet. All subsequent packets are then immediately dropped until this bit is set to 1b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| SBP      | 2      | 0b            | Store Bad Packets<br>0b = do not store.<br>1b = store bad packets.<br>This bit controls the MAC receive behavior. A packet is required to pass the address (or normal) filtering before the SBP bit becomes effective. If SBP = 0b, then all packets with layer 1 or 2 errors are rejected. The appropriate statistic would be increased. If SBP = 1b, then these packets are received (and transferred to host memory). The receive descriptor error field (RDESC.ERRORS) should have the corresponding bit(s) set to signal the software device driver that the packet is erred. In some operating systems the software device driver passes this information to the protocol stack. In either case, if a packet only has layer 3+ errors, such as IP or TCP checksum errors, and passes other filters, the packet is always received (layer 3+ errors are not used as a packet filter).<br><b>Note:</b> symbol errors before the SFD are ignored. Any packet must have a valid SFD (RX_DV with no RX_ER in 10/100/1000BASE-T mode) in order to be recognized by the I350 (even bad packets). Also, erred packets are not routed to the MNG even if this bit is set. |

| BAM   | 15     | 0b            | Broadcast Accept Mode.<br>0b = Ignore broadcast (unless it matches through exact or imperfect filters).<br>1b = Accept broadcast packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| BSIZE | 17:16  | 00b           | Receive Buffer Size<br>BSIZE controls the size of the receive buffers and permits software to trade-off descriptor performance versus required storage space. Buffers that are 2048 bytes require only one descriptor per receive packet maximizing descriptor efficiency.<br>00b = 2048 Bytes.<br>01b = 1024 Bytes.<br>10b = 512 Bytes.<br>11b = 256 Bytes.<br><b>Notes:</b><br>1. BSIZE should not be modified when RXEN is set to 1b. Set RXEN =0 when modifying the buffer size by changing this field.<br>2. BSIZE value only defines receive buffer size of queues with a <i>SRRCTL.BSIZEPACKET</i> value of 0. |
| VFE   | 18     | 0b            | VLAN Filter Enable<br>0b = Disabled (filter table does not decide packet acceptance).<br>1b = Enabled (filter table decides packet acceptance for 802.1Q packets).<br>Three bits [20:18] control the VLAN filter table. The first determines whether the table participates in the packet acceptance criteria. The next two are used to decide whether the CFI bit found in the 802.1Q packet should be used as part of the acceptance criteria.                                                                                                                                                                      |
| CFIEN | 19     | 0b            | Canonical Form Indicator Enable<br>0b = Disabled (CFI bit found in received 802.1Q packet's tag is not compared to decide packet acceptance).<br>1b = Enabled (CFI bit found in received 802.1Q packet's tag must match RCTL.CFI to accept 802.1Q type packet).                                                                                                                                                                                                                                                                                                                                                       |
| CFI   | 20     | 0b            | Canonical Form Indicator bit value<br>0b = 802.1Q packets with CFI equal to this field are accepted.<br>1b = 802.1Q packet is discarded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PSP   | 21     | 0b            | Pad Small Receive packets.<br>If this field is set, in virtualized operating mode, strip CRC ( <i>DVMOLR.CRC Strip</i> ) should be set for all functions otherwise <i>RCTL.SECRC</i> should be set.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DPF   | 22     | 0b            | Discard Pause Frames with Station MAC Address<br>Controls whether pause frames directly addressed to this station are forwarded to the host.<br>0b = incoming pause frames with station MAC address are forwarded to the host.<br>1b = incoming pause frames with station MAC address are discarded.<br><b>Note:</b> Pause frames with other MAC addresses (multicast address) are always discarded unless the specific address is added to the accepted MAC addresses (either multicast or unicast).                                                                                                                 |
| PMCF  | 23     | 0b            | Pass MAC Control Frames<br>Filters out unrecognized pause and other control frames.<br>0b = Filter MAC Control frames.<br>1b = Pass/forward MAC control frames to the Host that are not XON/XOFF Flow Control packets.<br>The <i>PMCF</i> bit controls the DMA function of the MAC control frames (other than flow control). A MAC control frame in this context must be addressed to either the MAC control frame multicast address or the station address, match the type field, and NOT match the PAUSE opcode of 0x0001. If <i>PMCF</i> = 1b then frames meeting this criteria are transferred to Host memory.    |

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Timestamp | 30     | 0b            | Timestamp Received packet<br>0 - Do not place timestamp at beginning of receive buffer.<br>1- Place timestamp at beginning of receive buffer. Timestamp is placed only in buffers of received packets that meet the criteria defined in the <i>TSYNCRXCTL.Type</i> field, 2-tuple filters or <i>ETQF</i> registers.<br>When set a 40 bit time stamp generated from the value in <i>SYSTIMH</i> and <i>SYSTIML</i> registers is placed in the receive buffer before the MAC header of the packets defined in the <i>TSYNCRXCTL.Type</i> field. |
| Drop_En   | 31     | 0b/1b         | Drop Enabled<br>If set, packets received to the queue when no descriptors are available to store them are dropped. The packet is dropped only if there are not enough free descriptors in the host descriptor ring to store the packet. If there are enough descriptors in the host, but they are not yet fetched by the I350, then the packet is not dropped and there are no release of packets until the descriptors are fetched.<br>Default is 0b for queue 0 and 1b for the other queues.                                                |

### 8.10.3 Packet Split Receive Type - PSRTYPE (0x5480 + 4\*n [n=0...7]; R/W)

This register enables or disables each type of header that needs to be split or replicated (refer to [Section 7.1.5](#) for additional information on header split support). Each register controls the behavior of 1 queue.

- Packet Split Receive Type Register (queue 0) - PSRTYPE0 (0x5480)
- Packet Split Receive Type Register (queue 1) - PSRTYPE1 (0x5484)
- Packet Split Receive Type Register (queue 2) - PSRTYPE2 (0x5488)
- Packet Split Receive Type Register (queue 3) - PSRTYPE3 (0x548C)
- Packet Split Receive Type Register (queue 4) - PSRTYPE4 (0x5490)
- Packet Split Receive Type Register (queue 5) - PSRTYPE5 (0x5494)
- Packet Split Receive Type Register (queue 6) - PSRTYPE6 (0x5498)
- Packet Split Receive Type Register (queue 7) - PSRTYPE7 (0x549C)

| Field      | Bit(s) | Initial Value | Description                                                 |

### 8.10.4 Replicated Packet Split Receive Type - RPLPSRTYPE (0x54C0; R/W)

This register enables or disables each type of header that needs to be split. This register controls the behavior of packets that are replicated to multiple queues.

| Field      | Bit(s) | Initial Value | Description                                                |
|------------|--------|---------------|------------------------------------------------------------|
| PSR_type0  | 0      | 0b            | Header includes MAC (VLAN/SNAP) only                       |
| PSR_type1  | 1      | 1b            | Header includes MAC, (VLAN/SNAP) IPv4 only                 |
| PSR_type2  | 2      | 1b            | Header includes MAC, (VLAN/SNAP) IPv4, TCP only            |
| PSR_type3  | 3      | 1b            | Header includes MAC, (VLAN/SNAP) IPv4, UDP only            |
| PSR_type4  | 4      | 1b            | Header includes MAC, (VLAN/SNAP) IPv4, IPv6 only           |
| PSR_type5  | 5      | 1b            | Header includes MAC, (VLAN/SNAP) IPv4, IPv6, TCP only      |
| PSR_type6  | 6      | 1b            | Header includes MAC, (VLAN/SNAP) IPv4, IPv6, UDP only      |
| PSR_type7  | 7      | 1b            | Header includes MAC, (VLAN/SNAP) IPv6 only                 |
| PSR_type8  | 8      | 1b            | Header includes MAC, (VLAN/SNAP) IPv6, TCP only            |
| PSR_type9  | 9      | 1b            | Header includes MAC, (VLAN/SNAP) IPv6, UDP only            |
| Reserved_1 | 10     | 1b            | Reserved<br>Write 1, ignore on read.                       |
| PSR_type11 | 11     | 1b            | Header includes MAC, (VLAN/SNAP) IPv4, TCP, NFS only       |
| PSR_type12 | 12     | 1b            | Header includes MAC, (VLAN/SNAP) IPv4, UDP, NFS only       |
| Reserved_1 | 13     | 1b            | Reserved<br>Write 1, ignore on read.                       |
| PSR_type14 | 14     | 1b            | Header includes MAC, (VLAN/SNAP) IPv4, IPv6, TCP, NFS only |
| PSR_type15 | 15     | 1b            | Header includes MAC, (VLAN/SNAP) IPv4, IPv6, UDP, NFS only |
| Reserved_1 | 16     | 1b            | Reserved<br>Write 1, ignore on read.                       |
| PSR_type17 | 17     | 1b            | Header includes MAC, (VLAN/SNAP) IPv6, TCP, NFS only       |
| PSR_type18 | 18     | 1b            | Header includes MAC, (VLAN/SNAP) IPv6, UDP, NFS only       |
| Reserved   | 31:19  | 0x0           | Reserved<br>Write 0, ignore on read.                       |

### 8.10.5 Receive Descriptor Base Address Low - RDBAL (0xC000 + 0x40\*n [n=0...7]; R/W)

This register contains the lower bits of the 64-bit descriptor base address. The lower four bits are always ignored. The Receive Descriptor Base Address must point to a 128 byte-aligned block of data.

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x2800, 0x2900, 0x2A00 & 0x2B00 respectively.

| Field <sup>1</sup> | Bit(s) | Initial Value | Description                                 |
|--------------------|--------|---------------|---------------------------------------------|
| Lower_0            | 6:0    | 0x0           | Ignored on writes.<br>Returns 0x0 on reads. |
| RDBAL              | 31:7   | X             | Receive Descriptor Base Address Low         |

1. Software should program *RDBAL[n]* register only when queue is disabled (*RXDCTL[n].Enable* = 0).

### 8.10.6 Receive Descriptor Base Address High - RDBAH (0xC004 + 0x40\*n [n=0...7]; R/W)

This register contains the upper 32 bits of the 64-bit descriptor base address.

| Field <sup>1</sup> | Bit(s) | Initial Value | Description                             |
|--------------------|--------|---------------|-----------------------------------------|
| RDBAH              | 31:0   | X             | Receive Descriptor Base Address [63:32] |

1. Software should program *RDBAH[n]* register only when queue is disabled (*RXDCTL[n].Enable* = 0).

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x2804, 0x2904, 0x2A04 & 0x2B04 respectively.

### 8.10.7 Receive Descriptor Ring Length - RDLEN (0xC008 + 0x40\*n [n=0...7]; R/W)

This register sets the number of bytes allocated for descriptors in the circular descriptor buffer. It must be 128-byte aligned.

| Field <sup>1</sup> | Bit(s) | Initial Value | Description                                                                                                                                  |
|--------------------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 0                  | 6:0    | 0x0           | Ignore on writes.<br>Bits 6:0 must be set to zero.<br>Bits 4:0 always read as zero.                                                          |
| LEN                | 19:7   | 0x0           | Descriptor Ring Length (number of 8 descriptor sets)<br>Note: maximum allowed value in <i>RDLEN</i> field 19:0 is 0x80000 (32K descriptors). |
| Reserved           | 31:20  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                         |

1. Software should program *RDLEN[n]* register only when queue is disabled (*RXDCTL[n].Enable* = 0).

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x2808, 0x2908, 0x2A08 & 0x2B08 respectively.

### 8.10.8 Receive Descriptor Head - RDH (0xC010 + 0x40\*n [n=0...7]; RO)

The value in this register might point to descriptors that are still not in host memory. As a result, the host cannot rely on this value in order to determine which descriptor to process.

| Field    | Bit(s) | Initial Value | Description                          |
|----------|--------|---------------|--------------------------------------|
| RDH      | 15:0   | 0x0           | Receive Descriptor Head              |
| Reserved | 31:16  | 0x0           | Reserved<br>Write 0, ignore on read. |

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x2810, 0x2910, 0x2A10 & 0x2B10 respectively.

### 8.10.9 Receive Descriptor Tail - RDT (0xC018 + 0x40\*n [n=0...7]; R/W)

This register contains the tail pointers for the receive descriptor buffer. The register points to a 16-byte datum. Software writes the tail register to add receive descriptors to the hardware free list for the ring.

**Note:** Writing the RDT register while the corresponding queue is disabled is ignored by the I350.  
In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x2818, 0x2918, 0x2A18 & 0x2B18 respectively.

| Field    | Bit(s) | Initial Value | Description                           |
|----------|--------|---------------|---------------------------------------|
| RDT      | 15:0   | 0x0           | Receive Descriptor Tail               |
| Reserved | 31:16  | 0x0           | Reserved.<br>Write 0, ignore on read. |

### 8.10.10 Receive Descriptor Control - RXDCTL (0xC028 + 0x40\*n [n=0...7]; R/W)

This register controls the fetching and write-back of receive descriptors. The three threshold values are used to determine when descriptors are read from and written to host memory. The values are in units of descriptors (each descriptor is 16 bytes).

| Field        | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTHRESH      | 4:0    | 0xC           | <p>Prefetch Threshold</p> <p>PTHRESH is used to control when a prefetch of descriptors is considered. This threshold refers to the number of valid, unprocessed receive descriptors the I350 has in its on-chip buffer. If this number drops below PTHRESH, the algorithm considers pre-fetching descriptors from host memory. This fetch does not happen unless there are at least HTHRESH valid descriptors in host memory to fetch.</p> <p><b>Note:</b> HTHRESH should be given a non zero value each time PTHRESH is used.</p> <p>Possible values for this field are 0 to 16.</p>                                                                                                                                                                                                                             |
| Reserved     | 7:5    | 0x0           | <p>Reserved</p> <p>Write 0, ignore on read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| HTHRESH      | 12:8   | 0xA           | <p>Host Threshold</p> <p>Field defines when receive descriptor prefetch is performed. Each time enough valid descriptors, as defined in the HTHRESH field, are available in host memory a prefetch is performed.</p> <p>Possible values for this field are 0 to 16.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Reserved     | 15:13  | 0x0           | <p>Reserved</p> <p>Write 0, ignore on read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| WTHRESH      | 20:16  | 0x1           | <p>Write-Back Threshold</p> <p>WTHRESH controls the write-back of processed receive descriptors. This threshold refers to the number of receive descriptors in the on-chip buffer that are ready to be written back to host memory. In the absence of external events (explicit flushes), the write-back occurs only after at least WTHRESH descriptors are available for write-back.</p> <p>Possible values for this field are 0 to 15.</p> <p><b>Note:</b> Since the default value for write-back threshold is 1b, the descriptors are normally written back as soon as one cache line is available. WTHRESH must contain a non-zero value to take advantage of the write-back bursting capabilities of the I350.</p> <p><b>Note:</b> It's recommended not to place a value above 0xC in the WTHRESH field.</p> |
| Reserved     | 24:21  | 0x0           | <p>Reserved</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ENABLE       | 25     | 0b            | <p>Receive Queue Enable</p> <p>When set, the <i>Enable</i> bit enables the operation of the specific receive queue.</p> <p>1b =Enables queue.<br/>0b =Disables queue.</p> <p>Setting this bit initializes Head and Tail registers (<i>RDH[n]</i> and <i>RDY[n]</i>) of the specific queue. Until then, the state of the queue is kept and can be used for debug purposes.</p> <p>When disabling a queue, this bit is cleared only after all activity in the queue has stopped.</p> <p><b>Note:</b> When receive queue is enabled and descriptors exist, descriptors are fetched immediately. Actual receive activity on port starts only if the <i>RCTL.RXEN</i> bit is set.</p>                                                                                                                                  |

| Reserved     | 31:27  | 0x0           | <p>Reserved</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Note:** In order to keep compatibility with 82575, for queues 0-3, these registers are aliased to addresses 0x2828, 0x2928, 0x2A28 & 0x2B28 respectively.

### 8.10.11 Receive Queue drop packet count - RQDPC (0xC030 + 0x40\*n [n=0...7]; RC)

| Field | Bit(s) | Initial Value | Description                                                                                                                                                                            |
|-------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RQDPC | 31:0   | 0x0           | Receive Queue drop packet count - counts the number of packets dropped by a queue due to lack of descriptors available.<br>Note: Counter is stuck when reaching a value of 0xFFFFFFFF. |

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x2830, 0x2930, 0x2A30 & 0x2B30 respectively.

Packets dropped due to the queue being disabled may not be counted by this register.

### 8.10.12 Receive Checksum Control - RXCSUM (0x5000; R/W)

The Receive Checksum Control register controls the receive checksum off loading features of the I350. The I350 supports the off loading of three receive checksum calculations: the Packet Checksum, the IP Header Checksum, and the TCP/UDP Checksum.

**Note:** This register should only be initialized (written) when the receiver is not enabled (only write this register when RCTL.RXEN = 0b)

| Field      | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PCSS       | 7:0    | 0x0           | <p>Packet Checksum Start</p> <p>Controls the packet checksum calculation. The packet checksum shares the same location as the RSS field and is reported in the receive descriptor when the <i>RXCSUM.PCSD</i> bit is cleared.</p> <p>If the <i>RXCSUM.IPPCSE</i> is set, the Packet checksum is aimed to accelerate checksum calculation of fragmented UDP packets. Please refer to section <a href="#">Section 7.1.7.2</a> for detailed explanation. If <i>RXCSUM.IPPCSE</i> is cleared (the default value), the checksum calculation that is reported in the Rx Packet checksum field is the unadjusted 16-bit ones complement of the packet.</p> <p>The packet checksum starts from the byte indicated by <i>RXCSUM.PCSS</i> (0b corresponds to the first byte of the packet), after VLAN stripping if enabled by the <i>CTRL.VME</i>. For example, for an Ethernet II frame encapsulated as an 802.3ac VLAN packet and with <i>RXCSUM.PCSS</i> set to 14, the packet checksum would include the entire encapsulated frame, excluding the 14-byte Ethernet header (DA, SA, Type/Length) and the 4-byte VLAN tag. The packet checksum does not include the Ethernet CRC if the <i>RCTL.SECRC</i> bit is set. Software must make the required offsetting computation (to back out the bytes that should not have been included and to include the pseudo-header) prior to comparing the packet checksum against the L4 checksum stored in the packet checksum. The partial checksum in the descriptor is aimed to accelerate checksum calculation of fragmented UDP packets.</p> <p><b>Note:</b> The PCSS value should point to a field that is before or equal to the IP header start. Otherwise the IP header checksum or TCP/UDP checksum is not calculated correctly.</p> |
| IPOFLD     | 8      | 1b            | <p>IP Checksum Off-load Enable</p> <p><i>RXCSUM.IPOFLD</i> is used to enable the IP Checksum off-loading feature. If <i>RXCSUM.IPOFLD</i> is set to 1b, the I350 calculates the IP checksum and indicates a pass/fail indication to software via the IP Checksum Error bit (<i>IPE</i>) in the <i>Error</i> field of the receive descriptor. Similarly, if <i>RXCSUM.TUOFLD</i> is set to 1b, the I350 calculates the TCP or UDP checksum and indicates a pass/fail indication to software via the TCP/UDP Checksum Error bit (<i>RDESC.L4E</i>).</p> <p>This applies to checksum off loading only. Supported frame types:</p> <ul style="list-style-type: none"><li>Ethernet II</li><li>Ethernet SNAP</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| TUOFLD     | 9      | 1b            | TCP/UDP Checksum Off-load Enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 8.10.15 Multicast Table Array - MTA (0x5200 + 4\*n [n=0...127]; R/W)

There is one register per 32 bits of the Multicast Address Table for a total of 128 registers. Software must mask to the desired bit on reads and supply a 32-bit word on writes. The first bit of the address used to access the table is set according to the RX\_CTRL.MO field.

**Note:** All accesses to this table must be 32 bit.

| Field      | Bit(s) | Initial Value | Description                                                                    |
|------------|--------|---------------|--------------------------------------------------------------------------------|
| Bit Vector | 31:0   | X             | Word wide bit vector specifying 32 bits in the multicast address filter table. |

Figure 8-1 shows the multicast lookup algorithm. The destination address shown represents the internally stored ordering of the received DA. Note that bit 0 indicated in this diagram is the first on the wire.

**Figure 8-1 Multicast Table Array**

### 8.10.16 Receive Address Low - RAL (0x5400 + 8\*n [n=0...15]; 0x54E0 + 8\*n [n=0...15]; R/W)

While "n" is the exact unicast/multicast address entry and it is equal to 0,1,...15.

These registers contain the lower bits of the 48 bit Ethernet address. All 32 bits are valid.

These registers are reset by a software reset or platform reset. If an EEPROM is present, the first register (RAL0) is loaded from the EEPROM after a software or platform reset.

**Note:** The RAL field should be written in network order.

| Field | Bit(s) | Initial Value | Description                                                                      |
|-------|--------|---------------|----------------------------------------------------------------------------------|
| RAL   | 31:0   | X             | Receive address low<br>Contains the lower 32-bit of the 48-bit Ethernet address. |

### 8.10.17 Receive Address High - RAH (0x5404 + 8\*n [n=0...15]; 0x54E4 + 8\*n [n=0...15]; R/W)

These registers contain the upper bits of the 48 bit Ethernet address. The complete address is [RAH, RAL]. The RAH.AV bit determines whether this address is compared against the incoming packet.

The RAH.ASEL field enables the I350 to perform special filtering on receive packets.

After reset, if an EEPROM is present, the first register (Receive Address Register 0) is loaded from the IA field in the EEPROM with its Address Select field set to 00b and its Address Valid field set to 1b. If no EEPROM is present, the Address Valid field is set to 0b and the Address Valid field for all of the other registers is set to 0b.

**Note:** The RAH field should be written in network order.

The first receive address register (RAH[0]) is also used for exact match pause frame checking (DA matches the first register). As a result, RAH[0] should always be used to store the individual Ethernet MAC address of the I350.

| Field    | Bit(s) | Initial Value                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                 |

This mode should not be used in virtualization mode.<br>10b = Reserved<br>11b = Reserved                                                                                                                                                                                 |
| POOLSEL  | 25:18  | 0x0                                                                 | Pool Select<br>In virtualization modes ( <i>MRQC.Multiple Receive Queues Enable</i> = 011b) indicates which Pool should get the packets matching this MAC address. This field is a bit map (bit per VM) where more than one bit can be set according to the limitations defined in <a href="#">Section 7.8.3.4</a> . If all the bits are zero, this address is used only for L2 filtering and is not used as part of the queueing decision. |
| Reserved | 29:26  | 0x0                                                                 | Reserved<br>Write 0, Ignore on reads.                                                                                                                                                                                                                                                                                                                                                                                                       |
| TRMCST   | 30     | 0x0                                                                 | Treat as Multicast. A transmit packet matching this destination address will be forwarded to the network even if forwarded also to a local pool.                                                                                                                                                                                                                                                                                            |
| AV       | 31     | 1b for RAH[0] if NVM is present, 0b otherwise<br>0b for all others. | Address Valid<br>Cleared after master reset. If an EEPROM is present, the <i>Address Valid</i> field of the Receive Address Register 0 is set to 1b after a software or PCI reset or EEPROM read.                                                                                                                                                                                                                                           |

### 8.10.18 VLAN Filter Table Array - VFTA (0x5600 + 4\*n [n=0...127]; R/W)

There is one register per 32 bits of the VLAN Filter Table. The size of the word array depends on the number of bits implemented in the VLAN Filter Table. Software must mask to the desired bit on reads and supply a 32-bit word on writes.

**Note:** All accesses to this table must be 32 bit.

The algorithm for VLAN filtering using the VFTA is identical to that used for the Multicast Table Array. Refer to [Section 8.10.15](#) for a block diagram of the algorithm. If VLANs are not used, there is no need to initialize the VFTA.

| Field      | Bit(s) | Initial Value | Description                                                              |
|------------|--------|---------------|--------------------------------------------------------------------------|
| Bit Vector | 31:0   | X             | Double-word wide bit vector specifying 32 bits in the VLAN Filter table. |

### 8.10.19 Multiple Receive Queues Command Register - MRQC (0x5818; R/W)

| Field                          | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multiple Receive Queues Enable | 2:0    | 0x0           | <p>Multiple Receive Queues Enable<br/>Enables support for Multiple Receive Queues and defines the mechanism that controls queue allocation.</p> <p>000b = Multiple receive queues as defined by filters (2-tuple filters, L2 Ether-type filters, SYN filter and Flex Filters).</p> <p>001b = Reserved. Reserved</p> <p>010b = Multiple receive queues as defined by filters and RSS for 8 queues<sup>1</sup>.</p> <p>011b = Multiple receive queues as defined by VMDq based on packet destination MAC address (<i>RAH.POOLSEL</i>) and Ether-type queuing decision filters.</p> <p>100b = Reserved</p> <p>101b = Reserved.</p> <p>110b = Reserved</p> <p>111b = Reserved.</p> <p>If VT is not supported, the only allowed values for this field are 000b, and 010b. Writing any other value is ignored.</p> <p>The allowed values for this field are 000b, 010b and 011b. Any other value is ignored.</p>                                                  |
| Def_Q                          | 5:3    | 0x0           | <p>Defines the default queue in non VMDq mode according to value of the <i>Multiple Receive Queues Enable</i> field.</p> <p>If Multiple Receive Queues Enable =</p> <p>000b: Def_Q defines the destination of all packets not forwarded by filters.</p> <p>001b: Def_Q field is ignored</p> <p>010b: Def_Q defines the destination of all packets not forwarded by RSS or filters.</p> <p>011b - Def_Q field is ignored. | Field            | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved         | 15:6   | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| RSS Field Enable | 31:16  | 0x0           | Each bit, when set, enables a specific field selection to be used by the hash function. Several bits can be set at the same time.<br>Bit[16] = Enable TcpIPv4 hash function<br>Bit[17] = Enable IPv4 hash function<br>Bit[18] = Enable TcpIPv6Ex hash function<br>Bit[19] = Enable IPv6Ex hash function<br>Bit[20] = Enable IPv6 hash function<br>Bit[21] = Enable TCPIPV6 hash function<br>Bit[22] = Enable UDPIPV4<br>Bit[23] = Enable UDPIPV6<br>Bit[24] = Enable UDPIPV6Ext<br>ReservedBits[31:26] - Reserved Zero |

1. Note that the *RXCSUM.PCSD* bit should be set to enable reception of the RSS hash value in the receive descriptor.

**Note:** The *MRQC.Multiple Receive Queues Enable* field is used to enable/disable RSS hashing and also to enable multiple receive queues. Disabling this feature is not recommended. Model usage is to reset the I350 after disabling the RSS.

### 8.10.20 RSS Random Key Register - RSSRK (0x5C80 + 4\*n [n=0...9]; R/W)

| Field | Bit(s) | Initial Value | Description                                    |
|-------|--------|---------------|------------------------------------------------|
| K0    | 7:0    | 0x0           | Byte n*4 of the RSS random key (n=0,1,...9).   |
| K1    | 15:8   | 0x0           | Byte n*4+1 of the RSS random key (n=0,1,...9). |
| K2    | 23:16  | 0x0           | Byte n*4+2 of the RSS random key (n=0,1,...9). |
| K3    | 31:24  | 0x0           | Byte n*4+3 of the RSS random key (n=0,1,...9). |

The RSS Random Key Register stores a 40 byte key used by the RSS hash function.

| 31    | 24 | 23   | 16 | 15   | 8 | 7     | 0 |
|-------|----|------|----|------|---|-------|---|
| K[3]  |    | K[2] |    | K[1] |   | K[0]  |   |
| ...   |    | ...  |    | ...  |   | ...   |   |
| K[39] |    | ...  |    | ...  |   | K[36] |   |

### 8.10.21 Redirection Table - RETA (0x5C00 + 4\*n [n=0...31]; R/W)

The redirection table is a 128-entry table with each entry being eight bits wide. Only 1 to 3 bits of each entry are used to store the queue index. The table is configured through the following R/W registers.

| Field   | Bit(s) | Initial Value | Description                                                                   |
|---------|--------|---------------|-------------------------------------------------------------------------------|
| Entry 0 | 7:0    | 0x0           | Determines the tag value and physical queue for index $4*n+0$ ( $n=0...31$ ). |
| Entry 1 | 15:8   | 0x0           | Determines the tag value and physical queue for index $4*n+1$ ( $n=0...31$ ). |
| Entry 2 | 23:16  | 0x0           | Determines the tag value and physical queue for index $4*n+2$ ( $n=0...31$ ). |
| Entry 3 | 31:24  | 0x0           | Determines the tag value and physical queue for index $4*n+3$ ( $n=0...31$ ). |

| 31      | 24 | 23    | 16 | 15    | 8 | 7     | 0 |
|---------|----|-------|----|-------|---|-------|---|
| Tag 3   |    | Tag 2 |    | Tag 1 |   | Tag 0 |   |
| ...     |    | ...   |    | ...   |   | ...   |   |
| Tag 127 |    | ...   |    | ...   |   | ...   |   |

Each entry (byte) of the redirection table contains the following:

| 7:3      | 2:0         |
|----------|-------------|
| Reserved | Queue index |

- Bits [7:3] - Reserved
- Bits [2:0] - Queue index for all pools or in regular RSS. In RSS only mode, all bits are used.

The contents of the redirection table are not defined following reset of the Memory Configuration Registers. System software must initialize the Table prior to enabling multiple receive queues. It can also update the redirection table during run time. Such updates of the table are not synchronized with the arrival time of received packets. Therefore, it is not guaranteed that a table update takes effect on a specific packet boundary.

**Note:** In case the operating system provides a redirection Table whose size is smaller than 128 bytes, the software usually replicates the operating system-provided redirection table to span the whole 128 bytes of the hardware's redirection table.

## 8.11 Filtering Register Descriptions

### 8.11.1 Immediate Interrupt RX - IMIR ( $0x5A80 + 4*n$ [ $n=0...7$ ]; R/W)

This  $IMIR[n]$  register,  $TTQF[n]$  register and the  $IMIREXT[n]$  register define the filtering required to indicate which packet triggers a low latency interrupt (immediate interrupt). The registers can also be used for queuing and deciding on timestamp of a packet.

#### Notes:

1. The *Port* field should be written in network order.

2. If one of the actions for this filter is set, then at least one of the *IMIR[n].PORT\_BP*, *IMIR[n].Size\_BP*, the Mask bits in the *TTQF[n]* register or the *IMIREXT.CtrlBit\_BP* bits should be cleared.
3. The value of the *IMIR* and *IMIREXT* registers after reset is unknown (apart from the *IMIR.Immediate Interrupt* bit which is guaranteed to be cleared). Therefore, both registers should be programmed before *IMIR.Immediate Interrupt* is set for a given flow.

| Field               | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Destination Port    | 15:0   | 0x0           | <p>Destination TCP port</p> <p>This field is compared with the Destination TCP port in incoming packets. Only a packet with a matching destination TCP port will trigger an immediate interrupt (if <i>IMIR[n].Immediate Interrupt</i> is set to 1b) and trigger the actions defined in the appropriate <i>TTQF[n]</i> register if all other filtering conditions are met.</p> <p><b>Note:</b> Enabled by the <i>IMIR.PORT_BP</i> bit.</p> |
| Immediate Interrupt | 16     | 0b            | <p>Enables issuing an immediate interrupt when the following conditions are met:</p> <ul style="list-style-type: none"> <li>• The 2-tuple filter associated with this register matches</li> <li>• The Length filter associated with this filter matches</li> <li>• The TCP flags filter associated with this filter matches</li> </ul>                                                                                                     |
| PORT_BP             | 17     | x             | <p>Port Bypass</p> <p>When set to 1b, the TCP port check is bypassed and only other conditions are checked.</p> <p>When set to 0b, the TCP port is checked to fit the port field.</p>                                                                                                                                                                                                                                                      |
| Reserved            | 28:18  | 0x0           | <p>Reserved</p> <p>Write 0, ignore on read.</p>                                                                                                                                                                                                                                                                                                                                                                                            |
| Filter Priority     | 31:29  | 000b          | <p>Defines the priority of the filter assuming two filters with same priority don't match. If two filters with the same priority match the incoming packet, the first filter (lowest ordinal number) is used in order to define the queue destination of this packet.</p>                                                                                                                                                                  |

## 8.11.2 Immediate Interrupt Rx Ext. - IMIREXT (0x5AA0 + 4\*n [n=0...7]; R/W)

| Field       | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Size_Thresh | 11:0   | X             | <p>Size Threshold</p> <p>These 12 bits define a size threshold. Only a packet with a length below this threshold will trigger an immediate interrupt (if <i>IMIR[n].Immediate Interrupt</i> is set to 1b) and trigger the actions defined in the appropriate <i>TTQF[n]</i> register (if <i>TTQF[n].Queue Enable</i> is set to 1b) if all other filtering conditions are met.</p> <p><b>Notes:</b></p> <ol style="list-style-type: none"> <li>1. Enabled by the <i>IMIREXT.Size_BP</i> bit.</li> <li>2. The size used for this comparison is the size of the packet as forwarded to the host and does not include any of the fields stripped by the MAC (VLAN or CRC). As a result, setting the <i>RCTL.SECRC</i> and <i>CTRL.VME</i> bits should be taken into account while calculating the size threshold.</li> <li>3. In virtualization mode, where <i>DVMOLR.CRC strip</i> and <i>DVMOLR.STRVLAN</i> are used, the <i>Size_thresh</i> should include the VLAN and the CRC.</li> </ol> |

| Field               | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                     |
|---------------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EType               | 15:0   | 0x0           | Identifies the protocol running on top of IEEE 802. Used to forward Rx packets containing this EType to a specific Rx queue.                                                                                                                    |
| Rx Queue            | 18:16  | 0x0           | Identifies the receive queue associated with this EType.                                                                                                                                                                                        |
| Reserved            | 25:19  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                            |
| Filter enable       | 26     | 0b            | When set, this filter is valid. Any of the actions controlled by the following fields are gated by this field.                                                                                                                                  |
| Reserved            | 28:27  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                            |
| Immediate Interrupt | 29     | 0x0           | When set, packets that match this filter generate an immediate interrupt.                                                                                                                                                                       |
| 1588 time stamp     | 30     | 0b            | When set, packets with this EType are time stamped according to the IEEE 1588 specification.<br><b>Note:</b> Packet will be time stamped only if it matches IEEE 1588 protocol according to the definition in the <i>TSYNCRXCTL.Type</i> field. |
| Queue Enable        | 31     | 0b            | When set, enables filtering of Rx packets by the EType defined in this register to the queue indicated in this register.                                                                                                                        |

## 8.12 Transmit Register Descriptions

### 8.12.1 Transmit Control Register - TCTL (0x0400; R/W)

This register controls all transmit functions for the I350.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved | 0      | 0b            | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| EN       | 1      | 0b            | Transmit Enable<br>The transmitter is enabled when this bit is set to 1b. Writing 0b to this bit stops transmission after any in progress packets are sent. Data remains in the transmit FIFO until the device is re-enabled. Software should combine this operation with reset if the packets in the TX FIFO should be flushed.                                                                                                                                                                                                                                                                                                                    |
| Reserved | 2      | 0b            | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PSP      | 3      | 1b            | Pad Short Packets<br>0b = Do not pad.<br>1b = Pad.<br>Padding makes the packet 64 bytes long. This is not the same as the minimum collision distance.<br>If padding of short packets is allowed, the total length of a packet not including FCS should be not less than 17 bytes.                                                                                                                                                                                                                                                                                                                                                                   |
| CT       | 11:4   | 0xF           | Collision Threshold<br>This determines the number of attempts at retransmission prior to giving up on the packet (not including the first transmission attempt). While this can be varied, it should be set to a value of 15 in order to comply with the IEEE specification requiring a total of 16 attempts. The Ethernet back-off algorithm is implemented and clamps to the maximum number of slot-times after 10 retries. This field only has meaning when in half-duplex operation.<br>Note: Software can choose to abort packet transmission in less than the Ethernet mandated 16 collisions. For this reason, hardware provides CT support. |
| BST      | 21:12  | 0x40          | Back-Off Slot Time<br>This value determines the back-off slot time value in byte time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| SWXOFF   | 22     | 0b            | Software XOFF Transmission<br>When set to 1b, the I350 schedules the transmission of an XOFF (PAUSE) frame using the current value of the PAUSE timer ( <i>FCTTV.TTV</i> ). This bit self-clears upon transmission of the XOFF frame.<br>Note: While 802.3x flow control is only defined during full duplex operation, the sending of PAUSE frames via the SWXOFF bit is not gated by the duplex settings within the I350. Software should not write a 1b to this bit while the I350 is configured for half-duplex operation.                                                                                                                       |
| Reserved | 23     | 0b            | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| RTLCL    | 24     | 0b            | Re-transmit on Late Collision<br>When set, enables the I350 to re-transmit on a late collision event.<br>Note: RTLCL configures the I350 to perform retransmission of packets when a late collision is detected. Note that the collision window is speed dependent: 64 bytes for 10/100 Mb/s and 512 bytes for 1000 Mb/s operation. If a late collision is detected when this bit is disabled, the transmit function assumes the packet has successfully transmitted. This bit is ignored in full-duplex mode.                                                                                                                                      |
| Reserved | 25     | 0b            | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## 8.12.2 Transmit Control Extended - TCTL\_EXT (0x0404; R/W)

This register controls late collision detection.

The COLD field is used to determine the latest time in which a collision indication is considered as a valid collision and not a late collision. When using the internal PHY, the default value of 0x40 provides a behavior consistent with the 802.3 spec requested behavior. However, when using an SGMII connected external PHY, the SGMII interface adds some delay on top of the time budget allowed by the specification (collisions in valid network topographies even after 512 bit time can be expected). In order to accommodate this condition, COLD should be updated to take the SGMII inbound and outbound delays.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                          |

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPGR     | 29:20  | 0x06          | <p>IPG After Deferral</p> <p>Specifies the total IPG time for non back-to-back transmissions (transmission following deferral) in half duplex.</p> <p>Measured in increments of the MAC clock:</p> <p>8 ns MAC clock when operating @ 1 Gb/s.</p> <p>80 ns MAC clock when operating @ 100 Mb/s</p> <p>800 ns MAC clock when operating @ 10 Mb/s.</p> <p>An offset of 5-byte times must be added to the programmed value to determine the total IPG after a defer event. A value of 7 is recommended to achieve a 12-byte effective IPG. Note that the IPGR must never be set to a value greater than IPGT. If IPGR is set to a value equal to or larger than IPGT, it overrides the IPGT IPG setting in half duplex resulting in inter-packet gaps that are larger than intended by IPGT. In this case, full duplex is unaffected and always relies on IPGT.</p> |
| Reserved | 31:30  | 00b           | <p>Reserved</p> <p>Write 0, ignore on read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## 8.12.4 Retry Buffer Control – RETX\_CTL (0x041C; RW)

This register controls the collision retry buffer.

| Field      | Bit(s) | Initial Value | Description                                                                                                                                              |
|------------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Water Mark | 3:0    | 0x3           | Retry buffer water mark. This parameters defines the minimal number of QWords that should be present in the retry buffer before transmission is started. |
| Reserved   | 31:4   | 0x0           | <p>Reserved.</p> <p>Write 0, ignore on read.</p>                                                                                                         |

## 8.12.5 DMA TX Control - DTXCTL (0x3590; R/W)

This register is used for controlling the DMA TX behavior.

| Field                   | Bit(s) | Initial Value | Description                                                                                                                                                                                      |

### 8.12.6 DMA TX TCP Flags Control Low - DTXTCPFLGL (0x359C; RW)

This register holds the buses that “AND” the control flags in TCP header for the first and middle segments of a TSO packet. Refer to [Section 7.2.4.7.1](#) and [Section 7.2.4.7.2](#) for details on the use of this register.

| Field             | Bit(s) | Initial Value | Description                                                                                                                           |
|-------------------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------|
| TCP_flg_first_seg | 11:0   | 0xFF6         | TCP Flags first segment. Bits that are used to execute an AND operation with the TCP flags in the TCP header in the first segment     |
| Reserved          | 15:12  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                  |
| TCP_Flg_mid_seg   | 27:16  | 0xF76         | TCP Flags middle segments. Bits that are used to execute an AND operation with the TCP flags in the TCP header in the middle segments |

### 8.12.7 DMA TX TCP Flags Control High - DTXTCPFLGH (0x35A0; RW)

This register holds the buses that “AND” the control flags in TCP header for the last segment of a TSO packet. Refer to [Section 7.2.4.7.3](#) for details of use of this register

| Field           | Bit(s) | Initial Value | Description                                                                                                                 |
|-----------------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------|
| TCP_Flg_lst_seg | 11:0   | 0xF7F         | TCP Flags last segment. Bits that are used to execute an AND operation with the TCP flags at TCP header in the last segment |
| Reserved        | 31:12  | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                       |

### 8.12.8 DMA TX Max Total Allow Size Requests - DTXMXSZRQ (0x3540; RW)

This register limits the allowable size of concurrent outstanding TX read requests from the host memory on the PCIe. Limiting the size of concurrent outstanding PCIe requests allows low latency packet read requests to be serviced in a timely manner, as the low latency request is serviced right after current outstanding requests are completed.

| Field             | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                          |
|-------------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max_bytes_num_req | 11:0   | 0x10          | Maximum allowable size of concurrent TX outstanding requests on PCIe. Field defines maximum size in 256 byte resolution of outstanding TX requests to be sent on PCIe. If total amount of outstanding TX requests is higher than defined in this field, no further TX outstanding requests are sent. |
| Reserved          | 31:12  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                 |

### 8.12.9 DMA TX Maximum Packet Size - DTXMXPKTSZ (0x355C; RW)

This register limits the total number of data bytes that might be transmitted in a single frame. Reducing packet size enables better utilization of transmit buffer.

| Field         | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAX_TPKT_SIZE | 8:0    | 0x98          | Maximum transmit packet size that is allowed to be transmitted by the driver. Value entered is in 64 Bytes resolution.<br><b>Notes:</b><br>1. Default value enables transmission of maximum sized 9,728 Byte Jumbo frames.<br>2. Values programmed in this field should not exceed 9,728 Bytes.<br>3. Value programmed should not exceed the TX buffer size programmed in the <i>ITPBS.TXPbsize</i> register. |
| Reserved      | 31:9   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                          |

### 8.12.10 Transmit Descriptor Base Address Low - TDBAL (0xE000 + 0x40\*n [n=0...7]; R/W)

These registers contain the lower 32 bits of the 64-bit descriptor base address. The lower 7 bits are ignored. The Transmit Descriptor Base Address must point to a 128-byte aligned block of data.

| Field <sup>1</sup> | Bit(s) | Initial Value | Description                                 |
|--------------------|--------|---------------|---------------------------------------------|
| Lower_0            | 6:0    | 0x0           | Ignored on writes.<br>Returns 0x0 on reads. |
| TDBAL              | 31:7   | X             | Transmit Descriptor Base Address Low        |

1. Software should program *TDBAL[n]* register only when queue is disabled (*TXDCTL[n].Enable* = 0).

**Note:** In order to keep compatibility with 82575, for queues 0-3, these registers are aliased to addresses 0x3800, 0x3900, 0x3A00 & 0x3B00 respectively.

### 8.12.11 Transmit Descriptor Base Address High - TDBAH (0xE004 + 0x40\*n [n=0...7]; R/W)

These registers contain the upper 32 bits of the 64-bit descriptor base address.

| Field <sup>1</sup> | Bit(s) | Initial Value | Description                              |
|--------------------|--------|---------------|------------------------------------------|
| TDBAH              | 31:0   | X             | Transmit Descriptor Base Address [63:32] |

1. Software should program *TDBAH[n]* register only when queue is disabled (*TXDCTL[n].Enable* = 0).

**Note:** In order to keep compatibility with 82575 for queues 0-3, these registers are aliased to addresses 0x3804, 0x3904, 0x3A04 & 0x3B04 respectively.

### 8.12.12 Transmit Descriptor Ring Length - TDLEN (0xE008 + 0x40\*n [n=0...7]; R/W)

These registers contain the descriptor ring length. The registers indicates the length in bytes and must be 128-byte aligned.

| Field <sup>1</sup> | Bit(s) | Initial Value | Description                                                                                                                                  |
|--------------------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 0                  | 6:0    | 0x0           | Ignore on writes.<br>Read back as 0x0.                                                                                                       |
| LEN                | 19:7   | 0x0           | Descriptor Ring Length (number of 8 descriptor sets)<br>Note: maximum allowed value in <i>TDLEN</i> field 19:0 is 0x80000 (32K descriptors). |
| Reserved           | 31:20  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                         |

1. Software should program *TDLEN[n]* register only when queue is disabled (*TXDCTL[n].Enable* = 0).

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x3808, 0x3908, 0x3A08 & 0x3B08 respectively.

### 8.12.13 Transmit Descriptor Head - TDH (0xE010 + 0x40\*n [n=0...7]; RO)

These registers contain the head pointer for the transmit descriptor ring. It points to a 16-byte datum. Hardware controls this pointer.

**Note:** The values in these registers might point to descriptors that are still not in host memory. As a result, the host cannot rely on these values in order to determine which descriptor to release.

| Field    | Bit(s) | Initial Value | Description                          |
|----------|--------|---------------|--------------------------------------|
| TDH      | 15:0   | 0x0           | Transmit Descriptor Head             |
| Reserved | 31:16  | 0x0           | Reserved<br>Write 0, ignore on read. |

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x3810, 0x3910, 0x3A10 & 0x3B10 respectively.

### 8.12.14 Transmit Descriptor Tail - TDT (0xE018 + 0x40\*n [n=0...7]; R/W)

These registers contain the tail pointer for the transmit descriptor ring and points to a 16-byte datum. Software writes the tail pointer to add more descriptors to the transmit ready queue. Hardware attempts to transmit all packets referenced by descriptors between head and tail.

| Field    | Bit(s) | Initial Value | Description                          |
|----------|--------|---------------|--------------------------------------|
| TDT      | 15:0   | 0x0           | Transmit Descriptor Tail             |
| Reserved | 31:16  | 0x0           | Reserved<br>Write 0, ignore on read. |

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x3818, 0x3918, 0x3A18 & 0x3B18 respectively.

### 8.12.15 Transmit Descriptor Control - TXDCTL (0xE028 + 0x40\*n [n=0...7]; R/W)

These registers control the fetching and write-back operations of transmit descriptors. The three threshold values are used to determine when descriptors are read from and written to host memory. The values are in units of descriptors (each descriptor is 16 bytes).

Since write-back of transmit descriptors is optional (under the control of *RS* bit in the descriptor), not all processed descriptors are counted with respect to *WTHRESH*. Descriptors start accumulating after a descriptor with *RS* set is processed. In addition, with transmit descriptor bursting enabled, some descriptors are written back that did not have *RS* set in their respective descriptors.

**Note:** When *WTHRESH* = 0x0, only descriptors with the *RS* bit set are written back.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTHRESH  | 4:0    | 0x0           | Prefetch Threshold<br>Controls when a prefetch of descriptors is considered. This threshold refers to the number of valid, unprocessed transmit descriptors the I350 has in its on-chip buffer. If this number drops below PTHRESH, the algorithm considers pre-fetching descriptors from host memory. However, this fetch does not happen unless there are at least HTHRESH valid descriptors in host memory to fetch.<br><b>Note:</b> When PTHRESH is 0x0 a Transmit descriptor fetch operation is done when any valid descriptors are available in Host memory and space is available in internal buffer. |
| Reserved | 7:5    | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| HTHRESH  | 12:8   | 0x0           | Host Threshold<br>Prefetch of transmit descriptors is considered when number of valid transmit descriptors in host memory is at least HTHRESH.<br><b>Note:</b> HTHRESH should be given a non zero value each time PTHRESH is used.                                                                                                                                                                                                                                                                                                                                                                           |
| Reserved | 15:13  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Field       | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WTHRESH     | 20:16  | 0x0           | <p>Write-Back Threshold</p> <p>Controls the write-back of processed transmit descriptors. This threshold refers to the number of transmit descriptors in the on-chip buffer that are ready to be written back to host memory. In the absence of external events (explicit flushes), the write-back occurs only after at least <i>WTHRESH</i> descriptors are available for write-back. Possible values for this field are 0 to 23.</p> <p><b>Note:</b> Since the default value for write-back threshold is 0b, descriptors are normally written back as soon as they are processed. <i>WTHRESH</i> must be written to a non-zero value to take advantage of the write-back bursting capabilities of the I350.</p> |
| Reserved    | 23:21  | 0x0           | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| ENABLE      | 25     | 0b            | <p>Transmit Queue Enable</p> <p>When set, this bit enables the operation of a specific transmit queue. Setting this bit initializes the Tail and Head registers (<i>TDH[n]</i> and <i>TDH[n]</i>) of a specific queue. Until then, the state of the queue is kept and can be used for debug purposes. When disabling a queue, this bit is cleared only after all transmit activity on this queue is stopped.</p> <p><b>Note:</b> When transmit queue is enabled and descriptors exist, descriptors and data are fetched immediately. Actual transmit activity on port starts only if the <i>TCTL.EN</i> bit is set.</p>                                                                                           |
| SWFLSH (WC) | 26     | 0b            | <p>Transmit Software Flush</p> <p>This bit enables software to trigger descriptor write-back flushing, independently of other conditions. This bit is self cleared by hardware. Bit will clear after write-back flush is triggered (may take a number of cycles).</p> <p><b>Note:</b> When working in head write-back mode (<i>TDWBAL.Head_WB_En</i> = 1) <i>TDWBAL.WB_on_EITR</i> bit should be set for transmit descriptor flush to occur.</p>                                                                                                                                                                                                                                                                  |
| Priority    | 27     | 0b            | <p>Transmit queue priority</p> <p>0 - Low priority<br/>1 - High priority</p> <p>When set, Transmit DMA resources are always allocated to the queue before low priority queues. Arbitration between transmit queues with same priority is done in a Round Robin fashion.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| HWBTHRESH   | 31:28  | 0x0           | <p>Transmit Head writeback threshold</p> <p>If value of field is greater than 0x0, head writeback to host will occur only when the amount of internal pending write backs exceeds this threshold. Refer to <a href="#">Section 7.2.3</a> for additional information.</p> <p><b>Note:</b> When activating this mode the <i>WB_on_EITR</i> bit in the <i>TDWBAL</i> register should be set to guarantee a write back after a timeout even if the threshold has not been reached.</p>                                                                                                                                                                                                                                |

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x3828, 0x3928, 0x3A28 and 0x3B28 respectively.

### 8.12.16 Tx Descriptor Completion Write – Back Address Low - TDWBAL (0xE038 + 0x40\*n [n=0...7]; R/W)

| Field <sup>1</sup> | Bit(s) | Initial Value | Description                                                                                                                                                                                                              |
|--------------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Head_WB_En         | 0      | 0b            | Head Write-Back Enable<br>1b = Head write-back is enabled.<br>0b = Head write-back is disabled.<br>When <i>head_WB_en</i> is set, <i>TXDCTL.SWFLSH</i> is ignored and no descriptor write-back is executed.              |
| WB_on_EITR         | 1      | 0b            | When set, a head write back is done upon EITR expiration.                                                                                                                                                                |
| HeadWB_Low         | 31:2   | 0x0           | Bits 31:2 of the head write-back memory location (DWORD aligned). Last 2 bits of this field are ignored and are always interpreted as 00b, meaning that the actual address is QWORD aligned.<br>Bits 1:0 are always 00b. |

1. Software should program TDWBAL[n] register only when queue is disabled (*TXDCTL[n].Enable* = 0).

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x3838, 0x3938, 0x3A38 & 0x3B38 respectively.

### 8.12.17 Tx Descriptor Completion Write-Back Address High - TDWBAH (0xE03C + 0x40\*n [n=0...7]; R/W)

| Field <sup>1</sup> | Bit(s) | Initial Value | Description                                             |
|--------------------|--------|---------------|---------------------------------------------------------|
| HeadWB_High        | 31:0   | 0x0           | Highest 32 bits of the head write-back memory location. |

1. Software should program TDWBAH[n] register only when queue is disabled (*TXDCTL[n].Enable* = 0).

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x383C, 0x393C, 0x3A3C & 0x3B3C respectively.

### 8.12.18 Transmit Queue drop packet count - TQDPC (0xE030 + 0x40\*n [n=0...7]; RW)

| Field | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                          |
|-------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TQDPC | 31:0   | 0x0           | Transmit Queue drop packet count - counts the number of packets dropped by a queue due to lack of space in the loopback buffer or due to security (anti - spoof) issues.<br>A multicast packet dropped by some of the destinations, but sent to others is counted by this counter<br>Note: Counter wraps around when reaching a value of 0xFFFFFFFF. |

## 8.13 DCA and TPH Register Descriptions

### 8.13.1 Rx DCA Control Registers - RXCTL (0xC014 + 0x40\*n [n=0...7]; R/W)

**Note:** RX data write no-snoop is activated when the NSE bit is set in the receive descriptor.

| Field                                       | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                               |

| CPUID                                   | 31:24  | 0x0           | Physical ID<br>Legacy DCA capable platforms - the device driver, upon discovery of the physical CPU ID and CPU Bus ID, programs the CPUID field with the Physical CPU and Bus ID associated with this Tx queue.<br>DCA 1.0 capable platforms - the device driver programs a value, based on the relevant APIC ID, associated with this Tx queue.<br>Refer to <a href="#">Table 3.1.3.1.2.3</a> for details<br>TPH capable platforms - the device driver programs a value, based on the relevant Socket ID, associated with this transmit queue.<br>Note that for TPH platforms, bits 31:27 of this field should always be set to zero. Refer to <a href="#">Section 7.7.2</a> for details. |

1. Both DCA Enable bit and TPH Enable bit should not be set for the same type of traffic.

**Note:** In order to keep compatibility with the 82575, for queues 0-3, these registers are aliased to addresses 0x3814, 0x3914, 0x3A14 & 0x3B14 respectively.

### 8.13.3 DCA Requester ID Information - DCA\_ID (0x5B70; RO)

The DCA requester ID field, composed of Device ID, Bus #, and Function # is set up in MMIO space for software to program the DCA Requester ID Authentication register.

| Field           | Bit(s) | Initial Value | Description                                                                                             |
|-----------------|--------|---------------|---------------------------------------------------------------------------------------------------------|
| Function Number | 2:0    | 000b          | Function Number<br>Function number assigned to the function based on BIOS/operating system enumeration. |
| Device Number   | 7:3    | 0x0           | Device Number<br>Device number assigned to the function based on BIOS/operating system enumeration.     |
| Bus Number      | 15:8   | 0x0           | Bus Number<br>Bus number assigned to the function based on BIOS/operating system enumeration.           |
| Reserved        | 31:16  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                    |

### 8.13.4 DCA Control - DCA\_CTRL (0x5B74; R/W)

This CSR is common to all functions.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|----------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DCA_DIS  | 0      | 1b            | DCA Disable<br>0b = DCA tagging is enabled.<br>1b = DCA tagging is disabled.                                                                                                                                                                                                                                                                                                                       |
| DCA_MODE | 4:1    | 0x0           | DCA Mode<br>000b = Legacy DCA is supported. The TAG field in the TLP header is based on the following coding: bit 0 is DCA enable; bits 3:1 are CPU ID).<br>001b = DCA 1.0 is supported. When DCA is disabled for a given message, the TAG field is 0000,0000b. If DCA is enabled, the TAG is set per queue as programmed in the relevant DCA Control register.<br>All other values are undefined. |
| Reserved | 8:5    | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                               |
| Desc_PH  | 10:9   | 00b           | Descriptor PH - defines the PH field used when a TPH hint is given for descriptor associated traffic (descriptor fetch, descriptor write back or head write back).                                                                                                                                                                                                                                 |
| Data_PH  | 12:11  | 10b           | Data PH - defines the PH field used when a TPH hint is given for data associated traffic (Tx data read, Rx data write).                                                                                                                                                                                                                                                                            |
| Reserved | 31:13  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                               |

## 8.14 Virtualization Register Descriptions

### 8.14.1 VMDq Control Register – VT\_CTL (0x581C; R/W)

| Field        | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                     |
|--------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved     | 6:0    | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                            |
| DEF_PL       | 9:7    | 000b          | Default pool - used to queue packets that did not pass any VM queuing decision.                                                                                                                                                                                                                 |
| Reserved     | 26:10  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                            |
| FLP          | 27     | 0b            | Filter local packets - filter incoming packets whose MAC source address matches one of the LAN port DA MAC addresses. If the SA of the received packet matches one of the DA in the RAH/RAL registers, then the VM tied to this DA does not receive the packet. Other VMs can still receive it. |
| IGMAC        | 28     | 0b            | If set, MAC address is ignored during pool decision. Pooling is based on VLAN only. This bit can be set only if the RCTL.VFE bit is set.                                                                                                                                                        |
| Dis_Def_Pool | 29     | 0b            | Drop if no pool is found. If this bit is asserted, then in a RX switching virtualized environment, if there is no destination pool, the packet is discarded and not sent to the default pool. Otherwise, it is sent to the pool defined by the DEF_PL field.                                    |
| Rpl_En       | 30     | 0b            | Replication Enable                                                                                                                                                                                                                                                                              |
| Reserved     | 31     | 0b            | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                            |

### 8.14.2 Physical Function Mailbox - PFMailbox (0x0C00 + 4\*n[n=0...7]; RW)

| Field     | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                    |
|-----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sts (WO)  | 0      | 0b            | Status/Command from PF ready. Setting this bit, causes an interrupt to the relevant VF. This bit always read as zero. Setting this bit sets the PFSTS bit in VFMailbox.                                                                        |
| Ack (WO)  | 1      | 0b            | VF message received. Setting this bit, causes an interrupt to the relevant VF. This bit always read as zero. Setting this bit sets the PFACK bit in VFMailbox.                                                                                 |
| VFU       | 2      | 0b            | Buffer is taken by VF. This bit is RO for the PF and is a mirror of the VFU bit of the VFMailbox register.                                                                                                                                     |
| PFU       | 3      | 0b            | Buffer is taken by PF. This bit can be set only if the VFU bit is cleared and is mirrored in the PFU bit of the VFMailbox register.                                                                                                            |
| RVFU (WO) | 4      | 0b            | Reset VFU - setting this bit clears the VFU bit in the corresponding VFMailbox register - this bit should be used only if the VF driver is stuck. Setting this bit is also reset the corresponding bits in the MBVFICR VFREQ and VFACK fields. |
| Reserved  | 31:5   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                           |

The usage of the mailbox register set is described in [Section 7.8.2.9.1](#).

### 8.14.3 Virtual Function Mailbox - VFMailbox (0x0C40 + 4\*n [n=0...7]; RW)

| Field      | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                           |
|------------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Req (WO)   | 0      | 0b            | Request for PF ready. Setting this bit, causes an interrupt to the PF. This bit always read as zero. Setting this bit sets the corresponding bit in <i>VFREQ</i> field in <i>MBVFICR</i> register.                                                                                                                                                                                    |
| Ack (WO)   | 1      | 0b            | PF message received. Setting this bit, causes an interrupt to the PF. This bit always read as zero. Setting this bit sets the corresponding bit in <i>VFACK</i> field in <i>MBVFICR</i> register.                                                                                                                                                                                     |
| VFU        | 2      | 0b            | Buffer is taken by VF. This bit can be set only if the PFU bit is cleared and is mirrored in the VFU bit of the PFMailbox register.                                                                                                                                                                                                                                                   |
| PFU        | 3      | 0b            | Buffer is taken by PF. This bit is RO for the VF and is a mirror of the PFU bit of the PFMailbox register.                                                                                                                                                                                                                                                                            |
| PFSTS (RC) | 4      | 0b            | PF wrote a message in the mailbox.                                                                                                                                                                                                                                                                                                                                                    |
| PFACK (RC) | 5      | 0b            | PF acknowledged the VF previous message.                                                                                                                                                                                                                                                                                                                                              |
| RSTI (RO)  | 6      | 1b            | Indicates that the PF has reset the shared resources and the reset sequence is in progress.<br><b>Notes:</b><br>1. Refer to <a href="#">Section 4.6.11.2.3</a> for additional information on <i>RSTI</i> usage.<br>2. When <i>CTRL_EXT.PFRSTD</i> is set, the <i>RSTI</i> bit in all the VFMailbox registers is cleared and the <i>RSTD</i> bit in all the VFMailbox register is set. |
| RSTD (RC)  | 7      | 0b            | Indicates that a PF software reset completed and the VF can start to use the device.<br><b>Note:</b> When <i>CTRL_EXT.PFRSTD</i> is set, the <i>RSTI</i> bit in all the VFMailbox registers is cleared and the <i>RSTD</i> bit in all the VFMailbox register is set.                                                                                                                  |
| Reserved   | 31:8   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                  |

### 8.14.4 Virtualization Mailbox Memory - VMBMEM (0x0800:0x083C + 0x40\*n [n=0...7]; R/W)

Mailbox memory for PF and VF drivers communication. Locations can be accessed as 32-bit or 64-bit words.

The memory is accessible to the PF and the VFs according to the following mapping.

| RAM address | Function | PF BAR 0 mapping <sup>1</sup> | VF BAR 0 mapping   |
|-------------|----------|-------------------------------|--------------------|
| 0 - 63      | VF0 ↔ PF | 0 - 63                        | VMBMEM:VMBMEM + 63 |
| 64 - 127    | VF1 ↔ PF | 64 - 127                      | VMBMEM:VMBMEM + 63 |
| ....        |          |                               |                    |
| 448 - 511   | VF7 ↔ PF | 448 - 511                     | VMBMEM:VMBMEM + 63 |

1. Relative to VMBMEM register.

| Field        | Bit(s) | Initial Value | Description  |
|--------------|--------|---------------|--------------|
| Mailbox Data | 31:0   | X             | Mailbox Data |

### 8.14.5 Mailbox VF Interrupt Causes Register - MBVFICR (0x0C80; R/W1C)

| Field    | Bit(s) | Initial Value | Description                          |
|----------|--------|---------------|--------------------------------------|
| VFREQ    | 7:0    | 0x0           | VF #n wrote a message.               |
| Reserved | 15:8   | 0x0           | Reserved<br>Write 0, ignore on read. |
| VFACK    | 23:16  | 0x0           | VF #n acknowledged a PF message.     |
| Reserved | 31:24  | 0x0           | Reserved<br>Write 0, ignore on read. |

### 8.14.6 Mailbox VF Interrupt Mask Register - MBVFIMR (0x0C84; RW)

| Field    | Bit(s) | Initial Value | Description                                                     |
|----------|--------|---------------|-----------------------------------------------------------------|
| VFIM     | 7:0    | 0xFF          | Mailbox indication from VF #n can cause an interrupt to the PF. |
| Reserved | 31:8   | 0x0           | Reserved<br>Write 0, ignore on read.                            |

### 8.14.7 FLR Events - VFLRE (0x0C88; R/W1C)

This register reflects the VFLR events of the different VFs. It is accessible only to the PF. These bits are cleared by writing 1.

| Field    | Bit(s) | Initial Value | Description                                       |
|----------|--------|---------------|---------------------------------------------------|
| VFLR     | 7:0    | X             | Reflects a VFLR event in VF7 to VF0 respectively. |
| Reserved | 31:8   | 0x0           | Reserved<br>Write 0, ignore on read.              |

### 8.14.8 VF Receive Enable- VFRE (0x0C8C; RW)

| Field    | Bit(s) | Initial Value | Description                                                                                                                            |
|----------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------|
| VFRE     | 7:0    | 0xFF          | Enables filtering process to forward packets to VF7 to VF0 respectively. Each bit is cleared by the relevant VFLR or by a VF SW reset. |
| Reserved | 31:8   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                   |

### 8.14.9 VF Transmit Enable - VFTE (0x0C90; RW)

| Field    | Bit(s) | Initial Value | Description                                                                                                                              |
|----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------|
| VFTE     | 7:0    | 0xFF          | Enables transmit process to forward packets from VF7 to VF0 respectively. Each bit is cleared by the relevant VF LR or by a VF SW reset. |
| Reserved | 31:8   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                     |

**Note:** Clearing one of VFTE bits may cause a transmit packet drop from the disabled queue.

### 8.14.10 Wrong VM Behavior Register - WVBR (0x3554; RC)

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                           |
|----------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WVM      | 7:0    | 0x0           | Bitmap indicating against which queue an anti spoof action or malicious action was taken. Once the register is read, the indication is cleared, but the queue is still blocked. The queue will be released only by a reset of the VF. |
| Reserved | 31:8   | 0x0           | Reserved                                                                                                                                                                                                                              |

### 8.14.11 Malicious Driver Free Block - MDFB (0x3558; RO)

| Field       | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                      |
|-------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Block Queue | 7:0    | 0x0           | Indicates queue that was blocked due to malicious behavior. When bit is set, to commence activity on offending queue, Software should toggle the corresponding bit in VFTE to release the queue. After that, the queue should be re-initialized. |
| Reserved    | 31:8   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                             |

### 8.14.12 VM Error Count Mask – VMECM (0x3510; RW)

| Field    | Bit(s) | Initial Value | Description                                                                                 |
|----------|--------|---------------|---------------------------------------------------------------------------------------------|
| Filter   | 7:0    | 0x0           | Defines if a packet dropped from pools 0 to 7 respectively is counted in the SSVPC counter. |
| Reserved | 31:8   | 0x0           | Reserved<br>Write 0, ignore on read.                                                        |

### 8.14.13 Last VM Misbehavior Cause – LVMMC (0x3548; RC)

Bits in LVMMC register define the cause for blocking the malicious queue that was reported in the *MDFB.Block Queue* field when *DTXCTL.MDP\_EN* is set. Refer to [Section 7.8.3.8.3](#) for details of the different bits.

**Note:** Only the first malicious event is registered for each packet, so if a bit is not set it doesn't mean that this event didn't occur, only that another malicious behavior was detected first.

| Field              | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                    |
|--------------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mac Header         | 0      | 0b            | Illegal MAC header size.                                                                                                                                                                                                                                                                       |
| IPv4 Header        | 1      | 0b            | Illegal IPv4 header size.                                                                                                                                                                                                                                                                      |

### 8.14.14 Queue Drop Enable Register - QDE (0x2408;RW)

This register allows the PF to override the *SRRCTL.drop\_en* bit set by the VF, to avoid head of line blocking issues if an un-trusted VF does not provide a receive descriptor to the hardware.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                     |
|----------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QDE      | 7:0    | 0x0           | Enable drop packets from queue 7 to 0 respectively. This bit overrides the <i>SRRCTL.drop_en</i> bit of each queue. If either of the bits is set, a packet received when no is descriptor available is dropped. |

### 8.14.15 TX Switch Control - TXSWC (0x5ACC; R/W)

This register controls the security settings of the switch and enables the loopback mode.

| Field       | Bit(s) | Initial Value | Description                                                                                                                                |
|-------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| MACAS       | 7:0    | 0x0           | Enable anti spoofing filter on MAC addresses for VF7 to VF0 respectively.                                                                  |
| VLANAS      | 15:8   | 0x0           | Enable anti spoofing filter on VLAN tags for VF7 to VF0 respectively.                                                                      |
| LLE         | 23:16  | 0x0           | Local loopback enable - when set, a packet originating from pool N and destined to pool N is looped back. If clear, the packet is dropped. |
| Reserved    | 30:24  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                       |
| Loopback_en | 31     | 0b            | Enable VMDQ loopback.                                                                                                                      |

### 8.14.16 VM VLAN Insert Register – VMVIR (0x3700 + 4 \* n [n=0...7]; RW)

| Field        | Bit(s) | Initial Value | Description                                                                                                                                                               |
|--------------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Port VLAN ID | 15:0   | 0x0           | Port VLAN tag to insert when VLAN action is to always insert default VLAN ( <i>VMVIR[n].vlana</i> = 01b).                                                                 |
| Reserved     | 29:16  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                      |
| vlana        | 31:30  | 0x0           | VLAN action:<br>00b = Use descriptor command (Refer to <a href="#">Section 7.2.2</a> ).<br>01b = Always insert Default VLAN<br>10b = Never insert VLAN<br>11b = Reserved. |

### 8.14.17 VM Offload Register - VMOLR (0x5AD0 + 4\*n [n=0...7]; RW)

This register controls part of the offload and queueing options applied to each pool (VM).

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rlpml    | 13:0   | 0x2600        | Long packet size (9k default)<br>If the packet is longer than a legal Ethernet packet, packet is removed from the pool list all the pools for which the <i>VMOLR.LPE</i> bit is not set or the packet length is larger than the value stated in the <i>VMOLR.RLPML</i> field (Refer to <a href="#">Section 7.8.3.4</a> for additional information).<br><b>Note:</b> Packet is longer than length of a legal Ethernet Packet if:<br>1. The packet is longer than 1518 bytes and there are no VLAN tags in the packet.<br>2. The packet is longer than 1522 bytes and there is one VLAN tag in the packet.<br>3. The packet is longer than 1526 bytes and there are two VLAN tags in the packet. |
| Reserved | 15:14  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### 8.14.18 DMA VM Offload Register - DVMOLR (0xC038 + 0x40\*n[n=0...7]; RW)

This register controls part of the offload and queueing options applied to each pool (VM).

| Field     | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                |
|-----------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved  | 28:0   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                       |
| Hide VLAN | 29     | 0b            | If this bit is set, a value of zero is written in the <i>RDESC.VLAN tag</i> and in the <i>RDESC.STATUS.VP</i> fields of the received descriptor.<br>If this bit is set for a VM, the <i>DVMOLR.STRVLAN</i> bit for this VM should be set also.                                             |
| STRVLAN   | 30     | 0b            | VLAN strip<br>If this bit is set, the VLAN is removed from the packet, and may be inserted in the receive descriptor (depending on the value of the Hide VLAN field).<br><b>Note:</b> If this bit is set the <i>DVMOLR[n].CRC strip</i> bit should be set as the CRC is not valid anymore. |

| Field     | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CRC strip | 31     | 1b            | CRC strip<br>If this bit is set, the CRC is removed from the packet.<br><b>Notes:</b> <ol style="list-style-type: none"> <li>1. If the <i>DVMOLR[n].STRVLAN</i> bit is set the <i>DVMOLR[n].CRC strip</i> bit should also be set as the CRC is not valid anymore.</li> <li>2. Even when bit is set, CRC strip is not done on runt packets (smaller than 64 Bytes).</li> <li>3. These bits should be cleared in non virtualized mode.</li> </ol> |

### 8.14.19 VLAN VM Filter - VLVF (0x5D00 + 4\*n [n=0...31]; RW)

This register set describes which VLANs the local VMs are part of. Each of the 32 registers contains a VLAN tag and a list of the VMs (VFs) which are part of it. Only packets with a VLAN matching one of the VLAN tags of which the VM is member of are forwarded to this VM.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                    |
|----------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN_Id  | 11:0   | 0x0           | Defines a VLAN tag, to which each VM whose bit is set in the POOLSEL field, belongs to.                                                                                                                        |
| POOLSEL  | 19:12  | 0x0           | Pool Select (bitmap)<br>Field defines to which VMs a packet with the VLAN_Id should be forwarded to. A bit is allocated to each of the 8 VMs, enabling forwarding the packet with the VLAN_Id to multiple VMs. |
| LVLAN    | 20     | 0x0           | This VLAN is local and packets with this VLAN should not be forwarded to the external NIC.                                                                                                                     |
| Reserved | 30:21  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                           |
| VI_En    | 31     | 0b            | VLAN Id Enable - this filter is valid.<br>Note: If <i>RCTL.VFE</i> is 0 all VLVF filters are disabled.                                                                                                         |

### 8.14.20 Unicast Table Array - UTA (0xA000 + 4\*n [n=0...127]; R/W)

There is one register per 32 bits of the Unicast Address Table for a total of 128 registers (the UTA[127:0] designation). Software must mask to the desired bit on reads and supply a 32-bit word on writes. The first bit of the address used to access the table is set according to the *RCTL.MO* field.

**Note:** All accesses to this table must be 32 bit.  
 The lookup algorithm is the same one used for the MTA table.  
 This table should be zeroed by software before start of work.

| Field      | Bit(s) | Initial Value | Description                                                                              |
|------------|--------|---------------|------------------------------------------------------------------------------------------|
| Bit Vector | 31:0   | X             | Word wide bit vector specifying 32 bits in the unicast destination address filter table. |

### 8.14.21 Storm Control - Control Register- SCCRL (0x5DB0; RW)

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                             |
|----------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MDIPW    | 0      | 0b            | Drop multicast packets (excluding flow control and manageability packets) if multicast threshold is exceeded in previous window                                                                                                                                                                                                         |
| MDICW    | 1      | 0b            | Drop multicast packets (excluding flow control and manageability packets) if multicast threshold is exceeded in current window                                                                                                                                                                                                          |

| Reserved | 31:19  | 0x0           | Reserved<br>Write 0, ignore on read.                                                      |

### 8.14.24 Multicast Storm Control Threshold - MSCTRH (0x5DBC; RW)

| Field    | Bit(s) | Initial Value | Description                                                                               |
|----------|--------|---------------|-------------------------------------------------------------------------------------------|
| UTRESH   | 18:0   | 0x0           | Traffic Upper Threshold-size: Represents the upper threshold for multicast storm control. |
| Reserved | 31:19  | 0x0           | Reserved<br>Write 0, ignore on read.                                                      |

### 8.14.25 Broadcast Storm Control Current Count - BSCCNT (0x5DC0; RO)

| Field    | Bit(s) | Initial Value | Description                                                                                                                               |
|----------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| CCOUNT   | 24:0   | 0x0           | IBSC Traffic Current Count: Represents the count of broadcast traffic received in the current time interval in units of 64-byte segments. |
| Reserved | 31:25  | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                                     |

### 8.14.26 Multicast Storm Control Current Count - MSCCNT (0x5DC4; RO)

| Field    | Bit(s) | Initial Value | Description                                                                                                                               |
|----------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| CCOUNT   | 24:0   | 0x0           | IMSC Traffic Current Count: Represents the count of multicast traffic received in the current time interval in units of 64-byte segments. |
| Reserved | 31:25  | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                                     |

### 8.14.27 Storm Control Time Counter - SCTC (0x5DC8; RO)

This register keeps track of the number of time units elapsed since the end of last time interval.

| Field    | Bit(s) | Initial Value | Description                                                                                            |
|----------|--------|---------------|--------------------------------------------------------------------------------------------------------|
| COUNT    | 9:0    | 0x0           | SC Time Counter: The counter for number of time units elapsed since the end of the last time interval. |
| Reserved | 31:10  | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                  |

### 8.14.28 Storm Control Basic Interval- SCBI (0x5DCC; RW)

This register defines the basic interval used as the base for the *SCCRL.Interval* counting in 10 Mb/s speed.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                      |
|----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BI       | 24:0   | 0x5F5E10      | Basic interval in 10 Mb/s port link rate in 16 ns clock cycles.<br><b>Notes:</b><br>1. Initial value defines a basic interval of 100 mS at 10 Mbps link speed.<br>2. The interval in 1Gb/s and 100Mb/s port link rates is 100 and 10 times smaller respectively. |
| Reserved | 31:25  | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                                            |

### 8.14.29 Virtual Mirror Rule Control - VMRCTL (0x5D80 + 0x4\*n [n= 0...3]; RW)

This register controls the rules to be applied and the destination port.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VPME     | 0      | 0b            | Virtual pool mirroring enable- reflects all the packets sent to a set of given VMs.                                                                                                                                                                                                                                                                                                                                                                 |
| UPME     | 1      | 0b            | Uplink port mirroring enable - reflects all the traffic received from the network.                                                                                                                                                                                                                                                                                                                                                                  |
| DPME     | 2      | 0b            | Downlink port mirroring enable - reflects all the traffic transmitted to the network.                                                                                                                                                                                                                                                                                                                                                               |
| VLME     | 3      | 0b            | VLAN mirroring enable - reflects all the traffic received in a set of given VLANs. bit enables mirroring operation based Either from the network or from local VMs.                                                                                                                                                                                                                                                                                 |
| Reserved | 7:4    | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                |
| MP       | 10:8   | 0x0           | VM Mirror port destination.<br>Packets destined to certain VLAN groups, are mirrored to the queue defined by the MP field, according to the <i>VMRVLAN</i> register. Packets destined to certain VMs, are mirrored to the queue defined by the MP field, according to the <i>VMRVM</i> register.<br>Note: If the <i>VMRCTL.UPME</i> bit is set to 1 all packets received on the port will be forwarded to the queue defined in the <i>MP</i> field. |
| Reserved | 31:11  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                |

### 8.14.30 Virtual Mirror Rule VLAN - VMRVLAN (0x5D90 + 0x4\*n [n= 0...3]; RW)

This register controls the VLAN tags as listed in the VLVF table taking part in the VLAN mirror rule.

| Field | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                 |
|-------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN  | 31:0   | 0x0           | Bitmap listing that defines which of the 32 VLANs defined in the VLVF registers participate in the mirror rule.<br>Packets that have a matching Vlan_ID as defined by the VLVF registers will also be forwarded (mirrored) to the queue defined in the VMRCTL.MP field, if the VMRCTL.VLME bit is set to 1. |

### 8.14.31 Virtual Mirror Rule VM - VMRVM (0x5DA0 + 0x4\*n [n= 0...3]; RW)

This register controls the VM as listed in the RAH registers taking part in the VM mirror rule.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                           |
|----------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VM       | 7:0    | 0x0           | Bitmap listing of VMs participating in the mirror rule.<br>Packets that are forwarded to the queues defined in the VMRVM.VM field, will also be forwarded (mirrored) to the queue defined in the VMRCTL.MP field, if the VMRCTL.VPME bit is set to 1. |
| Reserved | 31:8   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                  |

## 8.15 Timer Registers Description

### 8.15.1 Watchdog Setup - WDSTP (0x1040; R/W)

| Field                     | Bit(s) | Initial Value    | Description                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|--------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WD_Enable                 | 0      | 0b <sup>1</sup>  | Enable Watchdog Timer                                                                                                                                                                                                                                                                                                                                                 |
| WD_Timer_Load_enable (SC) | 1      | 0b               | Enables the load of the watchdog timer by writing to WD_Timer field. If this bit is not set, the WD_Timer field is loaded by the value of WD_Timeout.<br><b>Note:</b> Writing to this field is only for DFX purposes.                                                                                                                                                 |
| Reserved                  | 15:2   | 0x0              | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                  |
| WD_Timer (RWS)            | 23:16  | WD_Timeout       | Indicates the current value of the timer. Resets to the timeout value each time the I350 functional bit in Software Device Status register is set. If this timer expires, the WD interrupt to the firmware and the WD SDP is asserted. As a result, this timer is stuck at zero until it is re-armed.<br><b>Note:</b> Writing to this field is only for DFX purposes. |
| WD_Timeout                | 31:24  | 0x2 <sup>1</sup> | Defines the number of seconds until the watchdog expires. The granularity of this timer is 1 sec. The minimal value allowed for this register when the watchdog mechanism is enabled is two. Setting this field to 1b might cause the watchdog to expire immediately.<br><b>Note:</b> Only 4 LSB bits loaded from EEPROM.                                             |

1. Value read from the EEPROM.

## 8.15.2 Watchdog Software Device Status - WDSWSTS (0x1044; R/W)

| Field               | Bit(s) | Initial Value | Description                                                                                                                                                                                                                           |
|---------------------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dev_Functional (SC) | 0      | 0b            | Each time this bit is set, the watchdog timer is re-armed. This bit is self clearing.                                                                                                                                                 |
| Force_WD (SC)       | 1      | 0b            | Setting this bit causes the WD timer to expire immediately. The WD_timer field is set to 0b. It can be used by software in order to indicate some fatal error detected in the software or in the hardware. This bit is self clearing. |
| Reserved            | 23:2   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                  |
| Stuck Reason        | 31:24  | 0x0           | This field can be used by software to indicate to the firmware the reason the I350 is malfunctioning. The encoding of this field is software/firmware dependent. A value of 0 indicates a functional the I350.                        |

## 8.15.3 Free Running Timer - FRTIMER (0x1048; RWS)

This register reflects the value of a free running timer that can be used for various timeout indications. The register is reset by a PCI reset and/or software reset.

**Note:** Writing to this register is for DFX purposes only.

| Field       | Bit(s) | Initial Value | Description                                                  |
|-------------|--------|---------------|--------------------------------------------------------------|
| Microsecond | 9:0    | X             | Number of microseconds in the current millisecond.           |
| Millisecond | 19:10  | X             | Number of milliseconds in the current second.                |
| Seconds     | 31:20  | X             | Number of seconds from the timer start (up to 4095 seconds). |

## 8.15.4 TCP Timer - TCPTIMER (0x104C; R/W)

| Field          | Bit(s) | Initial Value | Description                                                                                                                                                                |
|----------------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Duration       | 7:0    | 0x0           | Duration<br>Duration of the TCP interrupt interval in msec.                                                                                                                |
| KickStart (WS) | 8      | 0b            | Counter Kick-Start<br>Writing a 1b to this bit kick-starts the counter down-count from the initial value defined in the <i>Duration</i> field. Writing a 0b has no effect. |

| Field               | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCPCountEn          | 9      | 0b            | <p>TCP Count Enable</p> <p>1b = TCP timer counting enabled.<br/>0b = TCP timer counting disabled.</p> <p>Once enabled, the TCP counter counts from its internal state. If the internal state is equal to 0b, the down-count does not restart until KickStart is activated. If the internal state is not 0b, the down-count continues from internal state.</p> <p>This enables a pause in the counting for debug purpose.</p> |
| TCPCountFinish (WS) | 10     | 0b            | <p>TCP Count Finish</p> <p>This bit enables software to trigger a TCP timer interrupt, regardless of the internal state.</p> <p>Writing a 1b to this bit triggers an interrupt and resets the internal counter to its initial value. Down-count does not restart until either KickStart is activated or Loop is set.</p> <p>Writing a 0b has no effect.</p>                                                                  |
| Loop                | 11     | 0b            | <p>TCP Loop</p> <p>When set to 1b, the TCP counter reloads duration each time it reaches zero, and continues down-counting from this point without kick-starting.</p> <p>When set to 0b, the TCP counter stops at a zero value and does not restart until KickStart is activated.</p> <p><b>Note:</b> Setting this bit alone is not enough to start the timer activity. The KickStart bit should also be set.</p>            |
| Reserved            | 31:12  | 0x0           | <p>Reserved.</p> <p>Write 0, ignore on read.</p>                                                                                                                                                                                                                                                                                                                                                                             |

## 8.16 Time Sync Register Descriptions

## 8.16.1 RX Time Sync Control Register - TSYNCRXCTL (0xB620;RW)

| Field     | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## 8.16.28 Time Sync Interrupt Registers

### 8.16.28.1 Time Sync Interrupt Cause Register - TSICR (0xB66C; RC/W1C)

**Note:** Once ICR.Time\_Sync is set, TSICR should be read to determine the actual interrupt cause and to enable reception of an additional ICR.Time\_Sync interrupt.

| Field    | Bit(s) | Initial Value | Description                                                                                                                                  |
|----------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| SYS WARP | 0      | 0b            | SYSTIM Warp around.<br>Set when SYSTIM Warp Around occurs. Warp around occurrence can be used by Software to update software time sync time. |
| TXTS     | 1      | 0b            | Transmit Time Stamp<br>Set when new timestamp is loaded into <i>TXSTMP</i> register                                                          |
| RXTS     | 2      | 0b            | Receive Time Stamp<br>Set when new timestamp is loaded into <i>RXSTMP</i> register                                                           |
| TT0      | 3      | 0b            | Target time 0 trigger.<br>Set when Target Time 0 ( <i>TRGTTIML/H0</i> ) trigger occurs.                                                      |
| TT1      | 4      | 0b            | Target time 1 trigger.<br>Set when Target Time 1 ( <i>TRGTTIML/H1</i> ) trigger occurs.                                                      |
| AUTT0    | 5      | 0b            | Auxiliary timestamp 0 taken.<br>Set when new timestamp is loaded into <i>AUXSTMP</i> 0 (auxiliary timestamp 0) register.                     |
| AUTT1    | 6      | 0b            | Auxiliary timestamp 1 taken.<br>Set when new timestamp is loaded into <i>AUXSTMP</i> 1 (auxiliary timestamp 1) register.                     |
| TADJ     | 7      | 0b            | Time Adjust 0 done<br>Set when Time Adjust to clock out 0 or 1 completed                                                                     |
| Reserved | 31:8   | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                                        |

### 8.16.28.2 Time Sync Interrupt Mask Register - TSIM (0xB674; RW)

| Field    | Bit(s) | Initial Value | Description                                                                                                                                      |
|----------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| SYS WARP | 0      | 0b            | SYSTIM Warp around Mask<br>0 – No Interrupt generated when <i>TSICR.SWARP</i> is set.<br>1 – Interrupt generated when <i>TSICR.SWARP</i> is set. |
| TXTS     | 1      | 0b            | Transmit Time Stamp Mask<br>0 – No Interrupt generated when <i>TSICR.TXTS</i> is set.<br>1 – Interrupt generated when <i>TSICR.TXTS</i> is set.  |
| RXTS     | 2      | 0b            | Receive Time Stamp Mask<br>0 – No Interrupt generated when <i>TSICR.RXTS</i> is set.<br>1 – Interrupt generated when <i>TSICR.RXTS</i> is set.   |
| TT0      | 3      | 0b            | Target time 0 Trigger Mask<br>0 – No Interrupt generated when <i>TSICR.TT0</i> is set.<br>1 – Interrupt generated when <i>TSICR.TT0</i> is set.  |

| Field    | Bit(s) | Initial Value | Description                                                                                                                                               |
|----------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| TT1      | 4      | 0b            | Target time 1 Trigger Mask<br>0 – No Interrupt generated when <i>TSICR.TT1</i> is set.<br>1 – Interrupt generated when <i>TSICR.TT1</i> is set.           |
| AUTT0    | 5      | 0b            | Auxiliary timestamp 0 taken Mask<br>0 – No Interrupt generated when <i>TSICR.AUTT0</i> is set.<br>1 – Interrupt generated when <i>TSICR.AUTT0</i> is set. |
| AUTT1    | 6      | 0b            | Auxiliary timestamp 1 taken Mask<br>0 – No Interrupt generated when <i>TSICR.AUTT1</i> is set.<br>1 – Interrupt generated when <i>TSICR.AUTT1</i> is set. |
| TADJ     | 7      | 0b            | Time Adjust 0 done mask<br>0 – No Interrupt generated when <i>TSICR.TADJ</i> is set.<br>1 – Interrupt generated when <i>TSICR.TADJ</i> is set.            |
| Reserved | 31:8   | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                                                     |

### 8.16.28.3 Time Sync Interrupt Set Register - TSIS (0xB670; WO)

*TSIS* register is Write Only. Writing 1 to a bit sets respective interrupt bit in *TSICR* register. Write operation causes a single interrupt event and bit is cleared internally.

| Field         | Bit(s) | Initial Value | Description                                                                                                                    |
|---------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| SYS WARP (SC) | 0      | 0b            | Set SYSTIM Warp Around Interrupt<br>0 – No <i>TSICR.SWARP</i> Interrupt set.<br>1 – <i>TSICR.SWARP</i> interrupt set.          |
| TXTS (SC)     | 1      | 0b            | Set Transmit Time Stamp Interrupt<br>0 – No <i>TSICR.TXTS</i> Interrupt set.<br>1 – <i>TSICR.TXTS</i> interrupt set.           |
| RXTS (SC)     | 2      | 0b            | Set Receive Time Stamp Interrupt<br>0 – No <i>TSICR.RXTS</i> Interrupt set.<br>1 – <i>TSICR.RXTS</i> Interrupt set.            |
| TT0 (SC)      | 3      | 0b            | Set Target Time 0 Trigger Interrupt<br>0 – No <i>TSICR.TT0</i> Interrupt set.<br>1 – <i>TSICR.TT0</i> Interrupt set.           |
| TT1 (SC)      | 4      | 0b            | Set Target Time 1 Trigger Interrupt<br>0 – No <i>TSICR.TT1</i> Interrupt set.<br>1 – <i>TSICR.TT1</i> Interrupt set.           |
| AUTT0 (SC)    | 5      | 0b            | Set Auxiliary Timestamp 0 Taken Interrupt<br>0 – No <i>TSICR.AUTT0</i> Interrupt set.<br>1 – <i>TSICR.AUTT0</i> Interrupt set. |
| AUTT1 (SC)    | 6      | 0b            | Set Auxiliary Timestamp 1 Taken Interrupt<br>0 – No <i>TSICR.AUTT1</i> Interrupt set.<br>1 – <i>TSICR.AUTT1</i> Interrupt set. |
| TADJ (SC)     | 7      | 0b            | Set Time Adjust 0 done Interrupt<br>0 – No <i>TSICR.TADJ</i> interrupt set.<br>1 – <i>TSICR.TADJ</i> interrupt set.            |
| Reserved      | 31:8   | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                          |

## 8.17 PCS Register Descriptions

These registers are used to configure the SerDes, SGMII and 1000BASE-KX PCS logic. Usage of these registers is described in [Section 3.7.4.1](#) & [Section 3.7.4.3](#).

### 8.17.1 PCS Configuration - PCS\_CFG (0x4200; R/W)

| Field       | Bit(s) | Initial Value | Description                                                                                                                                                                                                                               |
|-------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved    | 2:0    | 000b          | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                      |
| PCS Enable  | 3      | 1b            | PCS Enable<br>Enables the PCS logic of the MAC. Should be set in SGMII, 1000BASE-KX and SerDes mode for normal operation.<br>Clearing this bit disables RX/TX of both data and control codes. Use this to force link down at the far end. |
| Reserved    | 29:4   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                      |
| PCS Isolate | 30     | 0b            | PCS Isolate<br>Setting this bit isolates the PCS logic from the MAC's data path. PCS control codes are still sent and received.                                                                                                           |
| SRESET      | 31     | 0b            | Soft Reset<br>Setting this bit puts all modules within the MAC in reset except the Host Interface. The Host Interface is reset via HRST. This bit is NOT self clearing; GMAC is in a reset state until this bit is cleared.               |

### 8.17.2 PCS Link Control - PCS\_LCTL (0x4208; RW)

| Field | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                         |
|-------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FLV   | 0      | 0b            | Forced Link Value<br>This bit denotes the link condition when force link is set.<br>0b = Forced link down.<br>1b = Forced link up.                                                                                                                                                                  |
| FSV   | 2:1    | 10b           | Forced Speed Value<br>These bits denote the speed when force speed and duplex (PCS_LCTL.FSD) bit is set. This value is also used when AN is disabled or when in SerDes mode.<br>00b = 10 Mb/s (SGMII).<br>01b = 100 Mb/s (SGMII).<br>10b = 1000 Mb/s (SerDes/SGMII/1000BASE-KX).<br>11b = Reserved. |
| FDV   | 3      | 1b            | Forced Duplex Value<br>This bit denotes the duplex mode when force speed and duplex (PCS_LCTL.FSD) bit is set. This value is also used when AN is disabled or when in SerDes mode.<br>1b = Full duplex (SerDes/SGMII/1000BASE-KX).<br>0b = Half duplex (SGMII).                                     |
| FSD   | 4      | 0b            | Force Speed and Duplex<br>If this bit is set, then speed and duplex mode is forced to forced speed value and forced duplex value, respectively. Otherwise, speed and duplex mode are decided by internal AN/SYNC state machines.                                                                    |

| Field               | Bit(s) | Initial Value   | Description                                                                                                                                                                                                                                                                                                                                     |
|---------------------|--------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Force Link          | 5      | 0b              | Force Link<br>If this bit is set, then the internal LINK_OK variable is forced to forced link value (bit 0 of this register).<br>Otherwise, LINK_OK is decided by internal AN/SYNC state machines.                                                                                                                                              |
| LINK LATCH LOW (LL) | 6      | 0b              | Link Latch Low Enable<br>If this bit is set, then link OK going LOW (negative edge) is latched until a processor read. Afterwards, link OK is continuously updated until link OK again goes LOW (negative edge is seen).                                                                                                                        |
| Force Flow Control  | 7      | 0b              | 0 = Flow control mode is set according to the AN process by following Table 37-4 in the IEEE 802.3 spec.<br>1 = Flow control is set according to FC_TX_EN / FC_RX_EN bits in CTRL register.                                                                                                                                                     |
| Reserved            | 15:8   | 0x0             | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                            |
| AN_ENABLE           | 16     | 0b <sup>1</sup> | AN Enable<br>Setting this bit enables the AN process in SerDes operating mode.<br>Note: When link-up is forced (CTRL.SLU=1) the AN_ENABLE bit should be 0.                                                                                                                                                                                      |
| AN RESTART (SC)     | 17     | 0b              | AN Restart<br>Used to reset/restart the link auto-negotiation process when using SerDes mode. Setting this bit restarts the Auto-negotiation process.<br>This bit is self clearing.                                                                                                                                                             |
| AN TIMEOUT EN       | 18     | 1b <sup>1</sup> | AN Timeout Enable<br>This bit enables the AN Timeout feature. During AN, if the link partner does not respond with AN pages, but continues to send good IDLE symbols, then LINK UP is assumed. (This enables LINK UP condition when link partner is not AN-capable and does not affect otherwise).<br>This bit should not be set in SGMII mode. |
| AN SGMII BYPASS     | 19     | 0b              | AN SGMII Bypass<br>If this bit is set, then IDLE detect state is bypassed during AN in SGMII mode. This reduces the acknowledge time in SGMII mode.                                                                                                                                                                                             |
| AN SGMII TRIGGER    | 20     | 1b              | AN SGMII Trigger<br>If this bit is cleared, then AN is not automatically triggered in SGMII mode even if SYNC fails. AN is triggered only in response to PHY messages or by a manual setting like changing the AN Enable/Restart bits.                                                                                                          |
| Reserved            | 23:21  | 000b            | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                            |

### 8.17.7 Link Partner Ability Next Page - PCS\_LPABNP (0x4224; RO)

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CODE     | 10:0   | -             | Message/Un-formatted Code Field<br>The Message Field is an 11-bit wide field that encodes 2048 possible messages. Un-formatted Code Field is an 11-bit wide field that might contain an arbitrary value.                                                                                                                                                                                                                                                                                                                                                                          |
| TOGGLE   | 11     | -             | Toggle<br>This bit is used to ensure synchronization with the Link Partner during Next Page exchange. This bit always takes the opposite value of the <i>Toggle</i> bit in the previously exchanged Link Code Word. The initial value of the <i>Toggle</i> bit in the first Next Page transmitted is the inverse of bit 11 in the base Link Code Word and, therefore, can assume a value of 0b or 1b. The <i>Toggle</i> bit is set as follows:<br>0b = Previous value of the transmitted Link Code Word when 1b<br>1b = Previous value of the transmitted Link Code Word when 0b. |
| ACK2     | 12     | -             | Acknowledge 2<br>Used to indicate that a device has successfully received its Link Partners' Link Code Word.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| MSGPG    | 13     | -             | Message Page<br>This bit is used to differentiate a Message Page from an Un-formatted Page. The encoding is:<br>0b = Un-formatted page.<br>1b = Message page.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ACK      | 14     | -             | Acknowledge<br>The Link Partner has acknowledged Next Page reception.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Reserved | 31:16  | -             | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### 8.17.8 SFP I2C Command- I2CCMD (0x1028; R/W)

This register is used by software to read or write to the configuration registers in an SFP module when the *CTRL\_EXT.I2C Enabled* bit is set to 1.

**Note:** According to the SFP specification, only reads are allowed from this interface; however, SFP vendors also provide a writable register through this interface (for example, PHY registers). As a result, write capability is also supported.

| Field  | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                         |
|--------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DATA   | 15:0   | X             | Data<br>In a write command, software places the data bits and then the MAC shifts them out to the I <sup>2</sup> C bus. In a read command, the MAC reads these bits serially from the I <sup>2</sup> C bus and then software reads them from this location.<br><b>Note:</b> This field is read in byte order and not in word order. |
| REGADD | 23:16  | 0x0           | I <sup>2</sup> C Register Address<br>For example, register 0, 1, 2... 255.                                                                                                                                                                                                                                                          |
| PHYADD | 26:24  | 0x0           | Device Address bits 3 -1<br>The actual address used is b{1010, PHYADD[2:0], 0}.                                                                                                                                                                                                                                                     |
| OP     | 27     | 0b            | Op Code<br>0b = I <sup>2</sup> C write.<br>1b = I <sup>2</sup> C read.                                                                                                                                                                                                                                                              |

| R      | 29     | 0b            | Ready Bit<br>Set to 1b by the I350 at the end of the I <sup>2</sup> C transaction. For example, indicates a read or write has completed.<br>Reset by a software write of a command.                                                                                                                                                 |
| IE     | 30     | 0b            | Interrupt Enable<br>When set to 1b by software, it causes an Interrupt to be asserted to indicate the end of an I <sup>2</sup> C cycle (ICR.MDAC).Reserved                                                                                                                                                                          |
| E      | 31     | 0b            | Error<br>This bit set is to 1b by hardware when it fails to complete an I <sup>2</sup> C read. Reset by a software write of a command.<br>Note: Bit is valid only when Ready bit is set.                                                                                                                                            |

### 8.17.9 SFP I2C Parameters - I2CPARAMS (0x102C; R/W)

This register is used to set the parameters for the I<sup>2</sup>C access to the SFP module and to allow bit banging access to the I<sup>2</sup>C interface.

| Field      | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                     |
|------------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Write Time | 4:0    | 110b          | Write Time<br>Defines the delay between a write access and the next access. The value is in milliseconds. A value of zero is not valid.                                                                                                                                         |
| Read Time  | 7:5    | 010b          | Read Time<br>Defines the delay between a read access and the next access. The value is in microseconds. A value of Zero is not valid                                                                                                                                            |
| I2CBB_EN   | 8      | 0b            | I <sup>2</sup> C Bit Bang Enable<br>If set, the I <sup>2</sup> C_CLK and I <sup>2</sup> C_DATA lines are controlled via the CLK, DATA and DATA_OE_N fields of this register. Otherwise, they are controlled by the hardware machine activated via the I2CCMD or MDIC registers. |

| Field           | Bit(s) | Initial Value | Description                                                                                                                                                                               |
|-----------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLK             | 9      | 0b            | I <sup>2</sup> C Clock<br>While in bit bang mode, controls the value driven on the I2C_CLK pad of this port.                                                                              |
| DATA_OUT        | 10     | 0b            | I <sup>2</sup> C_DATA<br>While in bit bang mode and when the DATA_OE_N field is zero, controls the value driven on the I2C_DATA pad of this port.                                         |
| DATA_OE_N       | 11     | 0b            | I <sup>2</sup> C_DATA_OE_N<br>While in bit bang mode, controls the direction of the I2C_DATA pad of this port.<br>0b = Pad is output.<br>1b = Pad is input.                               |
| DATA_IN (RO)    | 12     | X             | I <sup>2</sup> C_DATA_IN<br>Reflects the value of the I2C_DATA pad. While in bit bang mode when the DATA_OE_N field is zero, this field reflects the value set in the DATA_OUT field.     |
| CLK_OE_N        | 13     | 0b            | I <sup>2</sup> C Clock Output Enable<br>While in bit bang mode, controls the direction of the I2C_CLK pad of this port.<br>0b = Pad is output.<br>1b = Pad is input.                      |
| CLK_IN (RO)     | 14     | X             | I <sup>2</sup> C Clock In Value<br>Reflects the value of the I2C_CLK pad. While in bit bang mode when the CLK_OE_N field is zero, this field reflects the value set in the CLK_OUT field. |
| clk_stretch_dis | 15     | 0b            | 0b - Enable slave clock stretching support in I <sup>2</sup> C access.<br>1b - Disable clock stretching support in I <sup>2</sup> C access.                                               |
| Reserved        | 31:16  | 0x0           | Reserved                                                                                                                                                                                  |

## 8.18 Statistics Register Descriptions

All Statistics registers reset when read. In addition, they stick at 0xFFFF\_FFFF when the maximum value is reached.

For the receive statistics it should be noted that a packet is indicated as received if it passes the I350's filters and is placed into the packet buffer memory. A packet does not have to be transferred to host memory in order to be counted as received.

Due to divergent paths between interrupt-generation and logging of relevant statistics counts, it might be possible to generate an interrupt to the system for a noteworthy event prior to the associated statistics count actually being increased. This is extremely unlikely due to expected delays associated with the system interrupt-collection and ISR delay, but might be observed as an interrupt for which statistics values do not quite make sense. Hardware guarantees that any event noteworthy of inclusion in a statistics count is reflected in the appropriate count within 1  $\mu$ s; a small time-delay prior to a read of statistics might be necessary to avoid the potential for receiving an interrupt and observing an inconsistent statistics count as part of the ISR.

### 8.18.1 CRC Error Count - CRCERRS (0x4000; RC)

Counts the number of receive packets with CRC errors. In order for a packet to be counted in this register, it must pass address filtering and must be 64 bytes or greater (from <Destination Address> through <CRC>, inclusively) in length. If receives are not enabled, then this register does not increment.

| Field | Bit(s) | Initial Value | Description     |
|-------|--------|---------------|-----------------|
| CEC   | 31:0   | 0x0           | CRC error count |

### 8.18.2 Alignment Error Count - ALGNERRC (0x4004; RC)

Counts the number of receive packets with alignment errors (the packet is not an integer number of bytes in length). In order for a packet to be counted in this register, it must pass address filtering and must be 64 bytes or greater (from <Destination Address> through <CRC>, inclusive) in length. If receives are not enabled, then this register does not increment. This register is valid only in MII mode during 10/100 Mb/s operation.

| Field | Bit(s) | Initial Value | Description           |
|-------|--------|---------------|-----------------------|
| AEC   | 31:0   | 0x0           | Alignment error count |

### 8.18.3 Symbol Error Count - SYMERRS (0x4008; RC)

Counts the number of symbol errors between reads. The count increases for every bad symbol received, whether or not a packet is currently being received and whether or not the link is up. When working in SerDes/SGMII/1000BASE-KX mode these statistics can be read from the SCVPC register.

| Field   | Bit(s) | Initial Value | Description        |
|---------|--------|---------------|--------------------|
| SYMERRS | 31:0   | 0x0           | Symbol Error Count |

### 8.18.4 RX Error Count - RXERRC (0x400C; RC)

Counts the number of packets received in which RX\_ER was asserted by the PHY. In order for a packet to be counted in this register, it must pass address filtering and must be 64 bytes or greater (from <Destination Address> through <CRC>, inclusive) in length. If receives are not enabled, then this register does not increment.

This register is not available in SerDes/SGMII/1000BASE-KX modes.

| Field | Bit(s) | Initial Value | Description    |
|-------|--------|---------------|----------------|
| RXEC  | 31:0   | 0x0           | RX error count |

### 8.18.5 Missed Packets Count - MPC (0x4010; RC)

Counts the number of missed packets. Packets are missed when the receive FIFO has insufficient space to store the incoming packet. This can be caused because of too few buffers allocated, or because there is insufficient bandwidth on the PCI bus. Events setting this counter causes *ICR.Rx Miss*, the Receiver Overrun Interrupt, to be set. This register does not increment if receives are not enabled.

These packets are also counted in the Total Packets Received register as well as in Total Octets Received.

| Field | Bit(s) | Initial Value | Description          |
|-------|--------|---------------|----------------------|
| MPC   | 31:0   | 0x0           | Missed Packets Count |

### 8.18.6 Single Collision Count - SCC (0x4014; RC)

This register counts the number of times that a successfully transmitted packet encountered a single collision. This register only increments if transmits are enabled (*TCTL.EN* is set) and the I350 is in half-duplex mode.

| Field | Bit(s) | Initial Value | Description                                                |
|-------|--------|---------------|------------------------------------------------------------|
| SCC   | 31:0   | 0x0           | Number of times a transmit encountered a single collision. |

### 8.18.7 Excessive Collisions Count - ECOL (0x4018; RC)

When 16 or more collisions have occurred on a packet, this register increments, regardless of the value of collision threshold. If collision threshold is set below 16, this counter won't increment. This register only increments if transmits are enabled (*TCTL.EN* is set) and the I350 is in half-duplex mode.

| Field | Bit(s) | Initial Value | Description                                     |
|-------|--------|---------------|-------------------------------------------------|
| ECC   | 31:0   | 0x0           | Number of packets with more than 16 collisions. |

### 8.18.8 Multiple Collision Count - MCC (0x401C; RC)

This register counts the number of times that a transmit encountered more than one collision but less than 16. This register only increments if transmits are enabled (*TCTL.EN* is set) and the I350 is in half-duplex mode.

| Field | Bit(s) | Initial Value | Description                                                            |
|-------|--------|---------------|------------------------------------------------------------------------|
| MCC   | 31:0   | 0x0           | Number of times a successful transmit encountered multiple collisions. |

## 8.18.9 Late Collisions Count - LATECOL (0x4020; RC)

Late collisions are collisions that occur after one slot time. This register only increments if transmits are enabled (*TCTL.EN* is set) and the I350 is in half-duplex mode.

| Field | Bit(s) | Initial Value | Description                             |
|-------|--------|---------------|-----------------------------------------|
| LCC   | 31:0   | 0x0           | Number of packets with late collisions. |

## 8.18.10 Collision Count - COLC (0x4028; RC)

This register counts the total number of collisions seen by the transmitter. This register only increments if transmits are enabled (*TCTL.EN* is set) and the I350 is in half-duplex mode.

| Field | Bit(s) | Initial Value | Description                                                |
|-------|--------|---------------|------------------------------------------------------------|
| CCC   | 31:0   | 0x0           | Total number of collisions experienced by the transmitter. |

## 8.18.11 Defer Count - DC (0x4030; RC)

This register counts defer events. A defer event occurs when the transmitter cannot immediately send a packet due to the medium being busy either because another device is transmitting, the IPG timer has not expired, half-duplex deferral events, reception of XOFF frames, or the link is not up. This register only increments if transmits are enabled (*TCTL.EN* is set). This counter does not increment for streaming transmits that are deferred due to TX IPG.

| Field | Bit(s) | Initial Value | Description             |
|-------|--------|---------------|-------------------------|
| CDC   | 31:0   | 0x0           | Number of defer events. |

## 8.18.12 Transmit with No CRS - TNCRS (0x4034; RC)

This register counts the number of successful packet transmissions in which the CRS input from the PHY was not asserted within one slot time of start of transmission from the MAC. Start of transmission is defined as the assertion of TX\_EN to the PHY.

The PHY should assert CRS during every transmission. Failure to do so might indicate that the link has failed, or the PHY has an incorrect link configuration. This register only increments if transmits are enabled (*TCTL.EN* is set). This register is not valid in SGMII mode and is only valid when the I350 is operating at half duplex.

| Field | Bit(s) | Initial Value | Description                                                   |
|-------|--------|---------------|---------------------------------------------------------------|
| TNCRS | 31:0   | 0x0           | Number of transmissions without a CRS assertion from the PHY. |

### 8.18.13 Host Transmit Discarded Packets by MAC Count - HTDPMC (0x403C; RC)

This register counts the number of packets sent by the host (and not the manageability engine) that are dropped by the MAC. This can include packets dropped because of excessive collisions or link fail events.

| Field  | Bit(s) | Initial Value | Description                                                 |
|--------|--------|---------------|-------------------------------------------------------------|
| HTDPMC | 31:0   | 0x0           | Number of packets sent by the host but discarded by the MAC |

### 8.18.14 Receive Length Error Count - RLEC (0x4040; RC)

This register counts receive length error events. A length error occurs if an incoming packet passes the filter criteria but is undersized or oversized. Packets less than 64 bytes are undersized. Packets over 1518, 1522 or 1526 bytes (according to the number of VLAN tags present) are oversized if Long Packet Enable (*RCTL.LPE*) is 0b. If *LPE* is 1b, then an incoming, packet is considered oversized if it exceeds the size defined in *RLPML.RLPML* field.

If receives are not enabled, this register does not increment. These lengths are based on bytes in the received packet from <Destination Address> through <CRC>, inclusive. Packets sent to the manageability engine are included in this counter.

**Note:** Runt packets smaller than 25 bytes may not be counted by this counter.

| Field | Bit(s) | Initial Value | Description                                   |
|-------|--------|---------------|-----------------------------------------------|
| RLEC  | 31:0   | 0x0           | Number of packets with receive length errors. |

### 8.18.15 XON Received Count - XONRXC (0x4048; RC)

This register counts the number of valid XON packets received. XON packets can use the global address, or the station address. This register only increments if receives are enabled (*RCTL.RXEN* is set).

| Field  | Bit(s) | Initial Value | Description                     |
|--------|--------|---------------|---------------------------------|
| XONRXC | 31:0   | 0x0           | Number of XON packets received. |

### 8.18.16 XON Transmitted Count - XONTXC (0x404C; RC)

This register counts the number of XON packets transmitted. These can be either due to a full queue or due to software initiated action (using *TCTL.SWXOFF*). This register only increments if transmits are enabled (*TCTL.EN* is set).

| Field  | Bit(s) | Initial Value | Description                        |
|--------|--------|---------------|------------------------------------|
| XONTXC | 31:0   | 0x0           | Number of XON packets transmitted. |

### 8.18.17 XOFF Received Count - XOFFRXC (0x4050; RC)

This register counts the number of valid XOFF packets received. XOFF packets can use the global address or the station address. This register only increments if receives are enabled (*RCTL.RXEN* is set).

| Field   | Bit(s) | Initial Value | Description                      |
|---------|--------|---------------|----------------------------------|
| XOFFRXC | 31:0   | 0x0           | Number of XOFF packets received. |

### 8.18.18 XOFF Transmitted Count - XOFFTXC (0x4054; RC)

This register counts the number of XOFF packets transmitted. These can be either due to a full queue or due to software initiated action (using *TCTL.SWXOFF*). This register only increments if transmits are enabled (*TCTL.EN* is set).

| Field   | Bit(s) | Initial Value | Description                         |
|---------|--------|---------------|-------------------------------------|
| XOFFTXC | 31:0   | 0x0           | Number of XOFF packets transmitted. |

### 8.18.19 FC Received Unsupported Count - FCRUC (0x4058; RC)

This register counts the number of unsupported flow control frames that are received.

The *FCRUC* counter increments when a flow control packet is received that matches either the reserved flow control multicast address (in the *FCAH/L* register) or the MAC station address, and has a matching flow control type field match (value in the *FCT* register), but has an incorrect opcode field. This register only increments if receives are enabled (*RCTL.RXEN* is set).

**Note:** When the *RCTL.PMCF* bit is set to 1b then the *FCRUC* counter will increment on reception of packets that don't match standard address filtering.

| Field | Bit(s) | Initial Value | Description                                         |
|-------|--------|---------------|-----------------------------------------------------|
| FCRUC | 31:0   | 0x0           | Number of unsupported flow control frames received. |

### 8.18.20 Packets Received [64 Bytes] Count - PRC64 (0x405C; RC)

This register counts the number of good packets received that are exactly 64 bytes (from <Destination Address> through <CRC>, inclusive) in length. Packets that are counted in the Missed Packet Count register are not counted in this register. Packets sent to the manageability engine are included in this counter. This register does not include received flow control packets and increments only if receives are enabled (*RCTL.RXEN* is set).

| Field | Bit(s) | Initial Value | Description                                             |
|-------|--------|---------------|---------------------------------------------------------|
| PRC64 | 31:0   | 0x0           | Number of packets received that are 64 bytes in length. |

### 8.18.21 Packets Received [65–127 Bytes] Count - PRC127 (0x4060; RC)

This register counts the number of good packets received that are 65-127 bytes (from <Destination Address> through <CRC>, inclusive) in length. Packets that are counted in the Missed Packet Count register are not counted in this register. Packets sent to the manageability engine are included in this counter. This register does not include received flow control packets and increments only if receives are enabled (*RCTL.RXEN* is set).

| Field  | Bit(s) | Initial Value | Description                                                 |
|--------|--------|---------------|-------------------------------------------------------------|
| PRC127 | 31:0   | 0x0           | Number of packets received that are 65-127 bytes in length. |

### 8.18.22 Packets Received [128–255 Bytes] Count - PRC255 (0x4064; RC)

This register counts the number of good packets received that are 128-255 bytes (from <Destination Address> through <CRC>, inclusive) in length. Packets that are counted in the Missed Packet Count register are not counted in this register. Packets sent to the manageability engine are included in this counter. This register does not include received flow control packets and increments only if receives are enabled (*RCTL.RXEN* is set).

| Field  | Bit(s) | Initial Value | Description                                                  |
|--------|--------|---------------|--------------------------------------------------------------|
| PRC255 | 31:0   | 0x0           | Number of packets received that are 128-255 bytes in length. |

### 8.18.23 Packets Received [256–511 Bytes] Count - PRC511 (0x4068; RC)

This register counts the number of good packets received that are 256-511 bytes (from <Destination Address> through <CRC>, inclusive) in length. Packets that are counted in the Missed Packet Count register are not counted in this register. Packets sent to the manageability engine are included in this counter. This register does not include received flow control packets and increments only if receives are enabled (*RCTL.RXEN* is set).

| Field  | Bit(s) | Initial Value | Description                                                  |
|--------|--------|---------------|--------------------------------------------------------------|
| PRC511 | 31:0   | 0x0           | Number of packets received that are 256-511 bytes in length. |

### 8.18.24 Packets Received [512–1023 Bytes] Count - PRC1023 (0x406C; RC)

This register counts the number of good packets received that are 512-1023 bytes (from <Destination Address> through <CRC>, inclusive) in length. Packets that are counted in the Missed Packet Count register are not counted in this register. Packets sent to the manageability engine are included in this counter. This register does not include received flow control packets and increments only if receives are enabled (*RCTL.RXEN* is set).

| Field   | Bit(s) | Initial Value | Description                                                   |
|---------|--------|---------------|---------------------------------------------------------------|
| PRC1023 | 31:0   | 0x0           | Number of packets received that are 512-1023 bytes in length. |

### 8.18.25 Packets Received [1024 to Max Bytes] Count - PRC1522 (0x4070; RC)

This register counts the number of good packets received that are from 1024 bytes to the maximum (from <Destination Address> through <CRC>, inclusive) in length. The maximum is dependent on the current receiver configuration (for example, *RCTL.LPE*, etc.) and the type of packet being received. If a packet is counted in Receive Oversized Count, it is not counted in this register (refer to [Section 8.18.37](#)). This register does not include received flow control packets and only increments if the packet has passed address filtering and receives are enabled (*RCTL.RXEN* is set). Packets sent to the manageability engine are included in this counter.

Due to changes in the standard for maximum frame size for VLAN tagged frames in 802.3, the I350 accepts packets that have a maximum length of 1522 bytes. The RMON statistics associated with this range has been extended to count 1522 byte long packets. If *CTRL\_EXT.EXT\_VLAN* is set, packets up to 1526 bytes are counted by this counter.

| Field   | Bit(s) | Initial Value | Description                                                   |
|---------|--------|---------------|---------------------------------------------------------------|
| PRC1522 | 31:0   | 0x0           | Number of packets received that are 1024-Max bytes in length. |

## 8.18.26 Good Packets Received Count - GPRC (0x4074; RC)

This register counts the number of good packets received of any legal length. The legal length for the received packet is defined by the value of Long Packet Enable (*RCTL.LPE*) (refer to [Section 8.18.37](#)). This register does not include received flow control packets and only counts packets that pass filtering. This register only increments if receives are enabled (*RCTL.RXEN* is set). This register does not count packets counted by the Missed Packet Count (*MPC*) register. Packets sent to the manageability engine (*MNGPRC*) or dropped by the VMDq queueing process (*SDPC*) are included in this counter.

**Note:** GPRC can count packets interrupted by a link disconnect although they have a CRC error.

| Field | Bit(s) | Initial Value | Description                                      |
|-------|--------|---------------|--------------------------------------------------|
| GPRC  | 31:0   | 0x0           | Number of good packets received (of any length). |

## 8.18.27 Broadcast Packets Received Count - BPRC (0x4078; RC)

This register counts the number of good (no errors) broadcast packets received. This register does not count broadcast packets received when the broadcast address filter is disabled. This register only increments if receives are enabled (*RCTL.RXEN* is set). This register does not count packets counted by the Missed Packet Count (*MPC*) register. Packets sent to the manageability engine (*MNGPRC*) or dropped by the VMDq queueing process (*SDPC*) are included in this counter.

| Field | Bit(s) | Initial Value | Description                           |
|-------|--------|---------------|---------------------------------------|
| BPRC  | 31:0   | 0x0           | Number of broadcast packets received. |

## 8.18.28 Multicast Packets Received Count - MPRC (0x407C; RC)

This register counts the number of good (no errors) multicast packets received. This register does not count multicast packets received that fail to pass address filtering nor does it count received flow control packets. This register only increments if receives are enabled (*RCTL.RXEN* is set). This register does not count packets counted by the Missed Packet Count (*MPC*) register. Packets sent to the manageability engine (*MNGPRC*) or dropped by the VMDq queueing process (*SDPC*) are included in this counter.

| Field | Bit(s) | Initial Value | Description                           |
|-------|--------|---------------|---------------------------------------|
| MPRC  | 31:0   | 0x0           | Number of multicast packets received. |

### 8.18.29 Good Packets Transmitted Count - GPTC (0x4080; RC)

This register counts the number of good (no errors) packets transmitted. A good transmit packet is considered one that is 64 or more bytes in length (from <Destination Address> through <CRC>, inclusively) in length. This does not include transmitted flow control packets. This register only increments if transmits are enabled (*TCTL.EN* is set).

| Field | Bit(s) | Initial Value | Description                         |
|-------|--------|---------------|-------------------------------------|
| GPTC  | 31:0   | 0x0           | Number of good packets transmitted. |

### 8.18.30 Good Octets Received Count - GORCL (0x4088; RC)

These registers make up a 64-bit register that counts the number of good (no errors) octets received. This register includes bytes received in a packet from the <Destination Address> field through the <CRC> field, inclusive; *GORCL* must be read before *GORCH*.

In addition, it sticks at 0xFFFF\_FFFF\_FFFF\_FFFF when the maximum value is reached. Only octets of packets that pass address filtering are counted in this register. This register does not count octets of packets counted by the Missed Packet Count (*MPC*) register. Octets of packets sent to the manageability engine are included in this counter. This register only increments if receives are enabled (*RCTL.RXEN* is set).

These octets do not include octets of received flow control packets.

| Field | Bit(s) | Initial Value | Description                                     |
|-------|--------|---------------|-------------------------------------------------|
| GORCL | 31:0   | 0x0           | Number of good octets received – lower 4 bytes. |

### 8.18.31 Good Octets Received Count - GORCH (0x408C; RC)

| Field | Bit(s) | Initial Value | Description                                     |
|-------|--------|---------------|-------------------------------------------------|
| GORCH | 31:0   | 0x0           | Number of good octets received – upper 4 bytes. |

### 8.18.32 Good Octets Transmitted Count - GOTCL (0x4090; RC)

These registers make up a 64-bit register that counts the number of good (no errors) packets transmitted. This register must be accessed using two independent 32-bit accesses; *GOTCL* must be read before *GOTCH*.

In addition, it sticks at 0xFFFF\_FFFF\_FFFF\_FFFF when the maximum value is reached. This register includes bytes transmitted in a packet from the <Destination Address> field through the <CRC> field, inclusive. This register counts octets in successfully transmitted packets that are 64 or more bytes in length. This register only increments if transmits are enabled (*TCTL.EN* is set).

These octets do not include octets in transmitted flow control packets.

| Field | Bit(s) | Initial Value | Description                                        |
|-------|--------|---------------|----------------------------------------------------|
| GOTCL | 31:0   | 0x0           | Number of good octets transmitted – lower 4 bytes. |

### 8.18.33 Good Octets Transmitted Count - GOTCH (0x4094; RC)

| Field | Bit(s) | Initial Value | Description                                        |
|-------|--------|---------------|----------------------------------------------------|
| GOTCH | 31:0   | 0x0           | Number of good octets transmitted – upper 4 bytes. |

### 8.18.34 Receive No Buffers Count - RNBC (0x40A0; RC)

This register counts the number of times that frames were received when there were no available buffers in host memory to store those frames (receive descriptor head and tail pointers were equal). The packet is still received if there is space in the FIFO. This register only increments if receives are enabled (*RCTL.RXEN* is set).

#### Notes:

1. This register does not increment when flow control packets are received.
2. If a packet is replicated, this counter counts each replication of the packet that is dropped.

| Field | Bit(s) | Initial Value | Description                             |
|-------|--------|---------------|-----------------------------------------|
| RNBC  | 31:0   | 0x0           | Number of receive no buffer conditions. |

### 8.18.35 Receive Undersize Count - RUC (0x40A4; RC)

This register counts the number of received frames that passed address filtering, and were less than minimum size (64 bytes from <Destination Address> through <CRC>, inclusive), and had a valid CRC. This register only increments if receives are enabled (*RCTL.RXEN* is set). Packets sent to the manageability engine are included in this counter.

**Note:** Runt packets smaller than 25 bytes may not be counted by this counter.

| Field | Bit(s) | Initial Value | Description                         |
|-------|--------|---------------|-------------------------------------|
| RUC   | 31:0   | 0x0           | Number of receive undersize errors. |

### 8.18.36 Receive Fragment Count - RFC (0x40A8; RC)

This register counts the number of received frames that passed address filtering, and were less than minimum size (64 bytes from <Destination Address> through <CRC>, inclusive), but had a bad CRC (this is slightly different from the Receive Undersize Count register). This register only increments if receives are enabled (*RCTL.RXEN* is set). Packets sent to the manageability engine are included in this counter.

**Note:** Runt packets smaller than 25 bytes may not be counted by this counter.

| Field | Bit(s) | Initial Value | Description                        |
|-------|--------|---------------|------------------------------------|
| RFC   | 31:0   | 0x0           | Number of receive fragment errors. |

### 8.18.37 Receive Oversize Count - ROC (0x40AC; RC)

This register counts the number of received frames with valid CRC field that passed address filtering, and were greater than maximum size. For definition of oversized packets, refer to [Section 7.1.1.4](#).

If receives are not enabled, this register does not increment. These lengths are based on bytes in the received packet from <Destination Address> through <CRC>, inclusive. Packets sent to the manageability engine are included in this counter.

| Field | Bit(s) | Initial Value | Description                        |
|-------|--------|---------------|------------------------------------|
| ROC   | 31:0   | 0x0           | Number of receive oversize errors. |

### 8.18.38 Receive Jabber Count - RJC (0x40B0; RC)

This register counts the number of received frames that passed address filtering, and were greater than maximum size and had a bad CRC (this is slightly different from the Receive Oversize Count register). For definition of oversized packets, refer to [Section 7.1.1.4](#).

If receives are not enabled, this register does not increment. These lengths are based on bytes in the received packet from <Destination Address> through <CRC>, inclusive. Packets sent to the manageability engine are included in this counter.

| Field | Bit(s) | Initial Value | Description                      |
|-------|--------|---------------|----------------------------------|
| RJC   | 31:0   | 0x0           | Number of receive jabber errors. |

### 8.18.39 Management Packets Received Count - MNGPRC (0x40B4; RC)

This register counts the total number of packets received that pass the management filters as described in [Section 10.3](#). Any packets with errors are not counted, except packets that are dropped because the management receive FIFO is full.

Packets sent to both the host and the management interface are not counted by this counter.

| Field  | Bit(s) | Initial Value | Description                            |
|--------|--------|---------------|----------------------------------------|
| MNGPRC | 31:0   | 0x0           | Number of management packets received. |

### 8.18.40 Management Packets Dropped Count - MPDC (0x40B8; RC)

This register counts the total number of packets received that pass the management filters as described in [Section 10.3](#), that are dropped because the management receive FIFO is full. Management packets include any packet directed to the manageability console (for example, BMC and ARP packets).

| Field | Bit(s) | Initial Value | Description                           |
|-------|--------|---------------|---------------------------------------|
| MPDC  | 31:0   | 0x0           | Number of management packets dropped. |

### 8.18.41 Management Packets Transmitted Count - MNGPTC (0x40BC; RC)

This register counts the total number of transmitted packets originating from the manageability path.

| Field | Bit(s) | Initial Value | Description                               |
|-------|--------|---------------|-------------------------------------------|
| MPTC  | 31:0   | 0x0           | Number of management packets transmitted. |

### 8.18.42 BMC2OS Packets Sent by BMC - B2OSPC (0x8FE0; RC)

This register counts the total number of transmitted packets sent from the manageability path that were sent to host. This includes packets received by the host and packet dropped in the I350 due to congestion conditions.

Counter is cleared when read by driver. Counter is also cleared by PCIe reset and Software reset. When reaching maximum value counter does not wrap-around.

| Field  | Bit(s) | Initial Value | Description                 |
|--------|--------|---------------|-----------------------------|
| B2OSPC | 31:0   | 0x0           | BMC2OS packets sent by BMC. |

### 8.18.43 BMC2OS Packets Received by host - B2OGPRC (0x4158; RC)

This register counts the total number of packets originating from the BMC that reached the host.

If a packet is replicated, this counter counts each replication of the packet.

Counter is cleared when read by driver. Counter is also cleared by PCIe reset and Software reset. When reaching maximum value counter does not wrap-around.

| Field   | Bit(s) | Initial Value | Description                      |
|---------|--------|---------------|----------------------------------|
| B2OGPRC | 31:0   | 0x0           | BMC2OS packets received by host. |

### 8.18.44 OS2BMC Packets Received by BMC - O2BGPTC (0x8FE4; RC)

This register counts the total number of packets originating from the host that reached the NC-SI interface.

Counter is cleared when read by driver. Counter is also cleared by PCIe reset and Software reset. When reaching maximum value counter does not wrap-around.

| Field   | Bit(s) | Initial Value | Description                         |
|---------|--------|---------------|-------------------------------------|
| O2BGPTC | 31:0   | 0x0           | OS2BMC good packets received count. |

### 8.18.45 OS2BMC Packets Transmitted by Host - O2BSPC (0x415C; RC)

This register counts the total number of packets originating from the function that were sent to the manageability path. This includes packets received by the BMC and packet dropped in the I350 due to congestion conditions.

Packets dropped due to security reasons, for example anti spoofing, are not counted by this counter.

Counter is cleared when read by driver. Counter is also cleared by PCIe reset and Software reset. When reaching maximum value counter does not wrap-around.

| Field  | Bit(s) | Initial Value | Description                         |
|--------|--------|---------------|-------------------------------------|
| O2BSPC | 31:0   | 0x0           | OS2BMC good packets received count. |

### 8.18.46 Total Octets Received - TORL (0x40C0; RC)

These registers make up a logical 64-bit register which counts the total number of octets received. This register must be accessed using two independent 32-bit accesses; TORL must be read before TORH. This register sticks at 0xFFFF\_FFFF\_FFFF\_FFFF when the maximum value is reached.

All packets received have their octets summed into this register, regardless of their length, whether they are erred, or whether they are flow control packets. This register includes bytes received in a packet from the <Destination Address> field through the <CRC> field, inclusive. This register only increments if receives are enabled (*RCTL.RXEN* is set).

**Note:** Broadcast rejected packets are counted in this counter (as opposed to all other rejected packets that are not counted).

| Field | Bit(s) | Initial Value | Description                                      |
|-------|--------|---------------|--------------------------------------------------|
| TORL  | 31:0   | 0x0           | Number of total octets received – lower 4 bytes. |

### 8.18.47 Total Octets Received - TORH (0x40C4; RC)

| Field | Bit(s) | Initial Value | Description                                      |
|-------|--------|---------------|--------------------------------------------------|
| TORH  | 31:0   | 0x0           | Number of total octets received – upper 4 bytes. |

### 8.18.48 Total Octets Transmitted - TOTL (0x40C8; RC)

These registers make up a 64-bit register that counts the total number of octets transmitted. This register must be accessed using two independent 32-bit accesses; TOTL must be read before TOTH. This register sticks at 0xFFFF\_FFFF\_FFFF\_FFFF when the maximum value is reached.

All transmitted packets have their octets summed into this register, regardless of their length or whether they are flow control packets. This register includes bytes transmitted in a packet from the <Destination Address> field through the <CRC> field, inclusive.

Octets transmitted as part of partial packet transmissions (for example, collisions in half-duplex mode) are not included in this register. This register only increments if transmits are enabled (*TCTL.EN* is set).

| Field | Bit(s) | Initial Value | Description                                         |
|-------|--------|---------------|-----------------------------------------------------|
| TOTL  | 31:0   | 0x0           | Number of total octets transmitted – lower 4 bytes. |

### 8.18.49 Total Octets Transmitted - TOTH (0x40CC; RC)

| Field | Bit(s) | Initial Value | Description                                         |
|-------|--------|---------------|-----------------------------------------------------|
| TOTH  | 31:0   | 0x0           | Number of total octets transmitted – upper 4 bytes. |

### 8.18.50 Total Packets Received - TPR (0x40D0; RC)

This register counts the total number of all packets received. All packets received are counted in this register, regardless of their length, whether they have errors, or whether they are flow control packets. This register only increments if receives are enabled (*RCTL.RXEN* is set).

**Notes:**

1. Broadcast rejected packets are counted in this counter (as opposed to all other rejected packets that are not counted).
2. Runt packets smaller than 25 bytes may not be counted by this counter.
3. *TPR* can count packets interrupted by a link disconnect although they have a CRC error.

| Field | Bit(s) | Initial Value | Description                     |
|-------|--------|---------------|---------------------------------|
| TPR   | 31:0   | 0x0           | Number of all packets received. |

### 8.18.51 Total Packets Transmitted - TPT (0x40D4; RC)

This register counts the total number of all packets transmitted. All packets transmitted are counted in this register, regardless of their length, or whether they are flow control packets.

Partial packet transmissions (collisions in half-duplex mode) are not included in this register. This register only increments if transmits are enabled (*TCTL.EN* is set). This register counts all packets, including standard packets, packets received over the SMBus, and packets generated by the PT function.

| Field | Bit(s) | Initial Value | Description                        |
|-------|--------|---------------|------------------------------------|
| TPT   | 31:0   | 0x0           | Number of all packets transmitted. |

### 8.18.52 Packets Transmitted [64 Bytes] Count - PTC64 (0x40D8; RC)

This register counts the number of packets transmitted that are exactly 64 bytes (from <Destination Address> through <CRC>, inclusive) in length. Partial packet transmissions (collisions in half-duplex mode) are not included in this register. This register does not include transmitted flow control packets (which are 64 bytes in length). This register only increments if transmits are enabled (*TCTL.EN* is set). This register counts all packets, including standard packets, packets received over the SMBus, and packets generated by the PT function.

| Field | Bit(s) | Initial Value | Description                                                |
|-------|--------|---------------|------------------------------------------------------------|
| PTC64 | 31:0   | 0x0           | Number of packets transmitted that are 64 bytes in length. |

### 8.18.53 Packets Transmitted [65–127 Bytes] Count - PTC127 (0x40DC; RC)

This register counts the number of packets transmitted that are 65-127 bytes (from <Destination Address> through <CRC>, inclusive) in length. Partial packet transmissions (for example, collisions in half-duplex mode) are not included in this register. This register only increments if transmits are enabled (*TCTL.EN* is set). This register counts all packets, including standard packets, packets received over the SMBus, and packets generated by the PT function.

| Field  | Bit(s) | Initial Value | Description                                                    |
|--------|--------|---------------|----------------------------------------------------------------|
| PTC127 | 31:0   | 0x0           | Number of packets transmitted that are 65-127 bytes in length. |

### 8.18.54 Packets Transmitted [128–255 Bytes] Count - PTC255 (0x40E0; RC)

This register counts the number of packets transmitted that are 128-255 bytes (from <Destination Address> through <CRC>, inclusive) in length. Partial packet transmissions (collisions in half-duplex mode) are not included in this register. This register only increments if transmits are enabled (*TCTL.EN* is set). This register counts all packets, including standard packets, packets received over the SMBus, and packets generated by the PT function.

| Field  | Bit(s) | Initial Value | Description                                                     |
|--------|--------|---------------|-----------------------------------------------------------------|
| PTC255 | 31:0   | 0x0           | Number of packets transmitted that are 128-255 bytes in length. |

### 8.18.55 Packets Transmitted [256–511 Bytes] Count - PTC511 (0x40E4; RC)

This register counts the number of packets transmitted that are 256-511 bytes (from <Destination Address> through <CRC>, inclusive) in length. Partial packet transmissions (for example, collisions in half-duplex mode) are not included in this register. This register only increments if transmits are enabled (*TCTL.EN* is set). This register counts all packets. Management packets must never be more than 200 bytes.

| Field  | Bit(s) | Initial Value | Description                                                     |
|--------|--------|---------------|-----------------------------------------------------------------|
| PTC511 | 31:0   | 0x0           | Number of packets transmitted that are 256-511 bytes in length. |

### 8.18.56 Packets Transmitted [512–1023 Bytes] Count - PTC1023 (0x40E8; RC)

This register counts the number of packets transmitted that are 512-1023 bytes (from <Destination Address> through <CRC>, inclusive) in length. Partial packet transmissions (for example, collisions in half-duplex mode) are not included in this register. This register only increments if transmits are enabled (*TCTL.EN* is set). This register counts all packets. Management packets must never be more than 200 bytes.

| Field   | Bit(s) | Initial Value | Description                                                      |
|---------|--------|---------------|------------------------------------------------------------------|
| PTC1023 | 31:0   | 0x0           | Number of packets transmitted that are 512-1023 bytes in length. |

### 8.18.57 Packets Transmitted [1024 Bytes or Greater] Count - PTC1522 (0x40EC; RC)

This register counts the number of packets transmitted that are 1024 or more bytes (from <Destination Address> through <CRC>, inclusive) in length. Partial packet transmissions (for example, collisions in half-duplex mode) are not included in this register. This register only increments if transmits are enabled (*TCTL.EN* is set).

Due to changes in the standard for maximum frame size for VLAN tagged frames in 802.3, the I350 transmits packets that have a maximum length of 1522 bytes. The RMON statistics associated with this range has been extended to count 1522 byte long packets. This register counts all packets. Management packets must never be more than 200 bytes. If *CTRL.EXT\_VLAN* is set, packets up to 1526 bytes are counted by this counter.

| Field   | Bit(s) | Initial Value | Description                                                          |
|---------|--------|---------------|----------------------------------------------------------------------|
| PTC1522 | 31:0   | 0x0           | Number of packets transmitted that are 1024 or more bytes in length. |

### 8.18.58 Multicast Packets Transmitted Count - MPTC (0x40F0; RC)

This register counts the number of multicast packets transmitted. This register does not include flow control packets and increments only if transmits are enabled (*TCTL.EN* is set).

| Field | Bit(s) | Initial Value | Description                              |
|-------|--------|---------------|------------------------------------------|
| MPTC  | 31:0   | 0x0           | Number of multicast packets transmitted. |

### 8.18.59 Broadcast Packets Transmitted Count - BPTC (0x40F4; RC)

This register counts the number of broadcast packets transmitted. This register only increments if transmits are enabled (*TCTL.EN* is set). This register counts all packets. Management packets must never be more than 200 bytes.

| Field | Bit(s) | Initial Value | Description                                    |
|-------|--------|---------------|------------------------------------------------|
| BPTC  | 31:0   | 0x0           | Number of broadcast packets transmitted count. |

### 8.18.60 TCP Segmentation Context Transmitted Count - TSCTC (0x40F8; RC)

This register counts the number of TCP segmentation offload transmissions and increments once the last portion of the TCP segmentation context payload is segmented and loaded as a packet into the on-chip transmit buffer. Note that it is not a measurement of the number of packets sent out (covered by other registers). This register only increments if transmits and TCP segmentation offload are enabled.

This counter only counts pure TSO transmissions.

| Field | Bit(s) | Initial Value | Description                                            |
|-------|--------|---------------|--------------------------------------------------------|
| TSCTC | 31:0   | 0x0           | Number of TCP Segmentation contexts transmitted count. |

### 8.18.61 Interrupt Assertion Count - IAC (0x4100; RC)

This counter counts the total number of LAN interrupts generated in the system. In case of MSI-X systems, this counter reflects the total number of MSI-X messages that are emitted.

| Field | Bit(s) | Initial Value | Description                                                             |
|-------|--------|---------------|-------------------------------------------------------------------------|
| IAC   | 31:0   | 0x0           | This is a count of all the LAN interrupt assertions that have occurred. |

### 8.18.62 Rx Packets to Host Count - RPTHC (0x4104; RC)

| Field | Bit(s) | Initial Value | Description                                                   |
|-------|--------|---------------|---------------------------------------------------------------|
| RPTHC | 31:0   | 0x0           | This is a count of all the received packets sent to the host. |

### 8.18.63 EEE TX LPI Count - TLPIC (0x4148; RC)

This register counts EEE TX LPI entry events. A EEE TX LPI event occurs when the transmitter enters EEE (IEEE802.3az) LPI state. This register only increments if transmits are enabled (*TCTL.EN* is set) and Link Mode is internal Copper PHY (*CTRL\_EXT.LINK\_MODE* = 00b).

| Field  | Bit(s) | Initial Value | Description                  |
|--------|--------|---------------|------------------------------|
| ETLPIC | 31:0   | 0x0           | Number of EEE TX LPI events. |

### 8.18.64 EEE RX LPI Count - RLPIC (0x414C; RC)

This register counts EEE RX LPI entry events. A EEE RX LPI event occurs when the receiver detects link partner entry into EEE (IEEE802.3az) LPI state. This register only increments if receives are enabled (*RCTL.RXEN* is set) and Link Mode is internal Copper PHY (*CTRL\_EXT.LINK\_MODE* = 00b).

| Field  | Bit(s) | Initial Value | Description                  |
|--------|--------|---------------|------------------------------|
| ERLPIC | 31:0   | 0x0           | Number of EEE RX LPI events. |

### 8.18.65 Host Good Packets Transmitted Count-HGPTC (0x4118; RC)

| Field | Bit(s) | Initial Value | Description                                     |
|-------|--------|---------------|-------------------------------------------------|
| HGPTC | 31:0   | 0x0           | Number of good packets transmitted by the host. |

This register counts the number of good (non-erred) packets transmitted sent by the host. A good transmit packet is considered one that is 64 or more bytes in length (from <Destination Address> through <CRC>, inclusively) in length. This does not include transmitted flow control packets or packets sent by the manageability engine. This register only increments if transmits are enabled (*TCTL.EN* is set).

### 8.18.66 Receive Descriptor Minimum Threshold Count-RXDMTC (0x4120; RC)

| Field  | Bit(s) | Initial Value | Description                                                        |
|--------|--------|---------------|--------------------------------------------------------------------|
| RXDMTC | 31:0   | 0x0           | This is a count of the receive descriptor minimum threshold events |

This register counts the number of events where the number of descriptors in one of the Rx queues was lower than the threshold defined for this queue.

### 8.18.67 Host Good Octets Received Count - HGORCL (0x4128; RC)

| Field  | Bit(s) | Initial Value | Description                                            |
|--------|--------|---------------|--------------------------------------------------------|
| HGORCL | 31:0   | 0x0           | Number of good octets received by host – lower 4 bytes |

### 8.18.68 Host Good Octets Received Count - HGORCH (0x412C; RC)

| Field  | Bit(s) | Initial Value | Description                                            |
|--------|--------|---------------|--------------------------------------------------------|
| HGORCH | 31:0   | 0x0           | Number of good octets received by host – upper 4 bytes |

These registers make up a logical 64-bit register which counts the number of good (non-erred) octets received. This register includes bytes received in a packet from the <Destination Address> field through the <CRC> field, inclusive. This register must be accessed using two independent 32-bit accesses.; HGORCL must be read before HGORCH.

In addition, it sticks at 0xFFFF\_FFFF\_FFFF\_FFFF when the maximum value is reached. Only packets that pass address filtering are counted in this register. This register counts only octets of packets that reached the host. The only exception is packets dropped by the DMA because of lack of descriptors in one of the queues. These packets are included in this counter.

This register only increments if receives are enabled (*RCTL.RXEN* is set).

### 8.18.69 Host Good Octets Transmitted Count - HGOTCL (0x4130; RC)

| Field  | Bit(s) | Initial Value | Description                                               |
|--------|--------|---------------|-----------------------------------------------------------|
| HGOTCL | 31:0   | 0x0           | Number of good octets transmitted by host – lower 4 bytes |

### 8.18.70 Host Good Octets Transmitted Count - HGOTCH (0x4134; RC)

| Field  | Bit(s) | Initial Value | Description                                               |
|--------|--------|---------------|-----------------------------------------------------------|
| HGOTCH | 31:0   | 0x0           | Number of good octets transmitted by host – upper 4 bytes |

These registers make up a logical 64-bit register which counts the number of good (non-erred) packets transmitted. This register must be accessed using two independent 32-bit accesses. This register resets whenever the upper 32 bits are read (HGOTCH).

In addition, it sticks at 0xFFFF\_FFFF\_FFFF\_FFFF when the maximum value is reached. This register includes bytes transmitted in a packet from the <Destination Address> field through the <CRC> field, inclusive. This register counts octets in successfully transmitted packets which are 64 or more bytes in length. This register only increments if transmits are enabled (*TCTL.EN* is set).

These octets do not include octets in transmitted flow control packets or manageability packets.

### 8.18.71 Length Error Count - LENERRS (0x4138; RC)

| Field   | Bit(s) | Initial Value | Description         |
|---------|--------|---------------|---------------------|
| LENERRS | 31:0   | 0x0           | Length error count. |

Counts the number of receive packets with Length errors. For example, valid packets (no CRC error) with a length/Type field with a value smaller or equal to 1500 greater than the frame size. In order for a packet to be counted in this register, it must pass address filtering and must be 64 bytes or greater (from <Destination Address> through <CRC>, inclusive) in length. If receives are not enabled, then this register does not increment.

### 8.18.72 SerDes/SGMII/KX Code Violation Packet Count - SCVPC (0x4228; RW)

This register contains the number of code violation packets received. Code violation is defined as an invalid received code in the middle of a packet.

| Field   | Bit(s) | Initial Value | Description                                                                                                                                                       |
|---------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CODEVIO | 31:0   | 0x0           | Code Violation Packet Count: At any point of time this field specifies number of unknown protocol packets received. Valid only in SGMII/SerDes/1000BASE-KX modes. |

### 8.18.73 Switch Security Violation Packet Count - SSVPC (0x41A0; RC)

This register counts Tx packets dropped due to switch security violations such as an SA anti spoof filtering. Relevant only in VMDq or IOV mode.

| Field | Bit(s) | Initial Value | Description                                                                                                                                           |
|-------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| SSVPC | 31:0   | 0x0           | Switch Security Violation Packet Count: This register counts Tx packets dropped due to switch security violations such as an SA anti spoof filtering. |

### 8.18.74 Switch Drop Packet Count - SDPC (0x41A4; RC/W)

| Field | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                      |
|-------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SDPC  | 31:0   | 0x0           | Switch Drop Packet Count: This register counts Rx packets dropped at the pool selection stage of the switch or by the storm control mechanism. For example, packets that were not routed to any of the pools and the <code>VT_CTL.Dis_Def_Pool</code> is set. Relevant only in VMDq or IOV mode. |

### 8.18.75 Loopback Full Buffer Drop Packet Count - LPBKFDPC (0x4150; RC/W)

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                              |
|----------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LPBKFDPC | 31:0   | 0x0           | Loopback buffer full drop packet count - counts the number of packets destined to the VM to VM loopback buffer that were dropped due to lack of space in the Loopback buffer.<br>Note: Counter does not wrap around when reaching a value of 0xFFFFFFFF. |

### 8.18.76 Management Full Buffer Drop Packet Count - MNGFBDPC (0x4154; RC/W)

| Field   | Bit(s) | Initial Value | Description                                                                                                                                                                                                                               |
|---------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MNGFDPC | 31:0   | 0x0           | Management buffer full drop packet count - counts the number of packets destined to Management that were dropped due to lack of space in the Management buffer.<br>Note: Counter does not wrap around when reaching a value of 0xFFFFFFFF |

## 8.18.77 Statistical Counters Per Queue

The I350 supports 9 statistical counters per queue to reduce processing overhead in virtualization operating mode.

These counters are reset only when the physical function is reset. When a VF is enabled, the PF should initialize these registers to zero.

### 8.18.77.1 Per Queue Good Packets Received Count - VFGPRC (0x10010 + n\*0x100 [n=0...7]; RW)

This register counts the number of legal length good packets received in queue[n]. The legal length for the received packet is defined by the value of Long Packet Enable (RCTL.LPE) (refer to [Section 8.18.37](#)). This register does not include received flow control packets and only counts packets that pass filtering. This register only increments if receive is enabled.

**Note:** VFGPRC may count packets interrupted by a link disconnect although they have a CRC error. Unlike some other statistics registers that are not allocated per VM, this register is not cleared on read. Furthermore, the register wraps around back to 0x0000 on the next increment when reaching a value of 0xFFFF and then continues normal count operation.

| Field | Bit(s) | Initial Value | Description                                      |
|-------|--------|---------------|--------------------------------------------------|
| GPRC  | 31:0   | 0x0           | Number of good packets received (of any length). |

### 8.18.77.2 Per Queue Good Packets Transmitted Count - VFGPTC (0x10014 + n\*0x100 [n=0...7]; RW)

This register counts the number of good (no errors) packets transmitted on queue[n]. A good transmit packet is considered one that is 64 or more bytes in length (from <Destination Address> through <CRC>, inclusively) in length. This does not include transmitted flow control packets. This register only increments if transmits are enabled (TCTL.EN is set). This counter includes loopback packets or packets later dropped by the MAC.

A multicast packet dropped by some of the destinations, but sent to others is counted by this counter

**Note:** Unlike some other statistic registers that are not allocated per VM, this register is not cleared on read. Furthermore, the register wraps around back to 0x0000 on the next increment when reaching a value of 0xFFFF and then continues normal count operation.

| Field | Bit(s) | Initial Value | Description                         |
|-------|--------|---------------|-------------------------------------|
| GPTC  | 31:0   | 0x0           | Number of good packets transmitted. |

### 8.18.77.3 Per Queue Good Octets Received Count - VFGORC (0x10018 + n\*0x100 [n=0...7]; RW)

This register counts the number of good (no errors) octets received on queue[n]. This register includes bytes received in a packet from the <Destination Address> field through the <CRC> field, inclusive.

Only octets of packets that pass address filtering are counted in this register. This register only increments if receive is enabled.

**Note:** VLAN tag is part of the byte count only if reported to the VM. I.e. if the DVMOLR.HIDE VLAN is not set for this VM. CRC is part of the byte count if DTXCTL.Count CRC is set.

Unlike some other statistic registers that are not allocated per VM, this register is not cleared on read. Furthermore, the register wraps around back to 0x0000 on the next increment when reaching a value of 0xFFFF and then continues normal count operation.

| Field | Bit(s) | Initial Value | Description                     |
|-------|--------|---------------|---------------------------------|
| GORC  | 31:0   | 0x0           | Number of good octets received. |

### 8.18.77.4 Per Queue Good Octets Transmitted Count - VFGOTC (0x10034 + n\*0x100 [n=0...7]; RW)

This register counts the number of good (no errors) packets transmitted on queue[n]. This register includes bytes transmitted in a packet from the <Destination Address> field through the <CRC> field, inclusive. Register also counts any padding that were added by the hardware. This register counts octets in successfully transmitted packets that are 64 or more bytes in length. Octets counted do not include octets in transmitted flow control packets. This register only increments if transmit is enabled.

A multicast packet dropped by some of the destinations, but sent to others is counted by this counter

**Note:** VLAN tag is part of the byte count only if inserted by the VM. I.e. if the VMVIR[n].VLANA field for the VM equals 00 (use descriptor command) and the packet contains a VLAN either in the packet or in the descriptor. CRC is part of the byte count if DTXCTL.Count CRC is set.

Unlike some other statistic registers that are not allocated per VM, this register is not cleared on read. Furthermore, the register wraps around back to 0x0000 on the next increment when reaching a value of 0xFFFF and then continues normal count operation.

| Field | Bit(s) | Initial Value | Description                                        |
|-------|--------|---------------|----------------------------------------------------|
| GOTC  | 31:0   | 0x0           | Number of good octets transmitted – lower 4 bytes. |

### 8.18.77.5 Per Queue Multicast Packets Received Count - VFMPRC (0x10038 + n\*0x100 [n=0...7]; RO)

This register counts the number of good (no errors) multicast packets received on queue[n]. This register does not count multicast packets received that fail to pass address filtering nor does it count received flow control packets. This register only increments if receive is enabled.

**Note:** Unlike some other statistic registers that are not allocated per VM, this register is not cleared on read. Furthermore, the register wraps around back to 0x0000 on the next increment when reaching a value of 0xFFFF and then continues normal count operation.

| Field | Bit(s) | Initial Value | Description                           |
|-------|--------|---------------|---------------------------------------|
| MPRC  | 31:0   | 0x0           | Number of multicast packets received. |

### 8.18.77.6 Good TX Octets loopback Count - VFGOTLBC (0x10050 + n\*0x100 [n=0...7]; RW)

This register counts the number of good (no errors) octets transmitted by the queues allocated to this VF that were sent to local VF. This counter includes packets that are sent to the LAN and to a local VM.

This register includes bytes transmitted in a packet from the <Destination Address> field through the <CRC> field, inclusive, including any padding added by the hardware. The VLAN tag added by the hardware is counted as part of the packet.

**Note:** VLAN tag is part of the byte count only if inserted by the VM. I.e. if the VMVIR[n].VLANA field for the VM equals 00 (use descriptor command) and the packet contains a VLAN either in the packet or in the descriptor. CRC is part of the byte count if DTXCTL.Count CRC is set.

Unlike some other statistics registers that are not allocated per VF, this register is not cleared on read. Furthermore, the register continues to count from 0x0000 on stepping beyond 0xFFFF.

| Field  | Bit(s) | Initial Value | Description                                   |
|--------|--------|---------------|-----------------------------------------------|
| GOTLBC | 31:0   | 0x0           | Number of good octets transmitted to loopback |

### 8.18.77.7 Good TX packets loopback Count - VFGPTLBC (0x10044+ n\*0x100 [n=0...7]; RW)

This register counts the number of good (no errors) packets transmitted by the queues allocated to this VF that were sent to local VF. This counter includes packets that are sent to the LAN and to a local VM.

**Note:** Unlike some other statistics registers that are not allocated per VF, this register is not cleared on read. Furthermore, the register continues to count from 0x0000 on stepping beyond 0xFFFF.

| Field  | Bit(s) | Initial Value | Description                                    |
|--------|--------|---------------|------------------------------------------------|
| GPTLBC | 31:0   | 0x0           | Number of good packets transmitted to loopback |

### 8.18.77.8 Good RX Octets loopback Count - VFGORLBC (0x10048+ n\*0x100 [n=0...7]; RW)

This register counts the number of good (no errors) octets received by the queues allocated to this VF that were sent from some local VFs.

**Note:** VLAN tag is part of the byte count only if reported to the VM. I.e. if the DVMOLR.HIDE VLAN is not set for this VM. CRC is part of the byte count if DTXCTL.Count CRC is set.  
Unlike some other statistics registers that are not allocated per VF, this register is not cleared on read. Furthermore, the register continues to count from 0x0000 on stepping beyond 0xFFFF.

| Field  | Bit(s) | Initial Value | Description                                  |
|--------|--------|---------------|----------------------------------------------|
| GORLBC | 31:0   | 0x0           | Number of good octets received from loopback |

### 8.18.77.9 Good RX Packets loopback Count - VFGPRLBC (0x10040+ n\*0x100 [n=0...7]; RW)

This register counts the number of good (no errors) packets received by the queues allocated to this VF that were sent from some local VFs.

**Note:** Unlike some other statistics registers that are not allocated per VF, this register is not cleared on read. Furthermore, the register continues to count from 0x0000 on stepping beyond 0xFFFF.

| Field  | Bit(s) | Initial Value | Description                                   |
|--------|--------|---------------|-----------------------------------------------|
| GPRLBC | 31:0   | 0x0           | Number of good packets received from loopback |

## 8.19 Manageability Statistics

This section describes a set of statistics counters used by the NC-SI interface and are not accessible to the host driver.

### 8.19.1 BMC Management Receive Packets Dropped Count - BMRPDC (0x4140; RC)

This register counts the total number of packets received that pass the management filters as described in [Section 10.3](#), that are dropped because the management receive FIFO is full. Management packets include any packet directed to the manageability console (for example, BMC and ARP packets). This register is available to the firmware only.

| Field | Bit(s) | Initial Value | Description                           |
|-------|--------|---------------|---------------------------------------|
| MPDC  | 31:0   | 0x0           | Number of management packets dropped. |

### 8.19.2 BMC Management Transmit Packets Dropped Count - BMTPDC (0x8FDC; RC)

This register counts the total number of packets received from the Out of Band Management interface, that are dropped because the management transmit FIFO is full or if the relevant NC-SI channel is disabled. This counter increases only if the packet is not sent to any destination (Host or Network).

**Note:** This register is available to Firmware only and is shared for BMC TX traffic destined to any of the ports.

| Field  | Bit(s) | Initial Value | Description                           |
|--------|--------|---------------|---------------------------------------|
| BMTPDC | 31:0   | 0x0           | Number of management packets dropped. |

### 8.19.3 BMC Management Packets Transmitted Count - BMNGPTC (0x4144; RC)

This register counts the total number of transmitted packets originating from the manageability path. This counter increases once if the packet is sent to any destination (host or network).

This register is available to the firmware only.

| Field | Bit(s) | Initial Value | Description                               |
|-------|--------|---------------|-------------------------------------------|
| MPTC  | 31:0   | 0x0           | Number of management packets transmitted. |

### 8.19.4 BMC Management Packets Received Count - BMNGPRC (0x413C; RC)

This register counts the total number of packets received that pass the management filters as described in [Section 10.3](#). Any packets with errors are not counted, except packets that are dropped because the management receive FIFO is full.

This register is available to the firmware only.

| Field  | Bit(s) | Initial Value | Description                            |
|--------|--------|---------------|----------------------------------------|
| MNGPRC | 31:0   | 0x0           | Number of management packets received. |

### 8.19.5 BMC Total Unicast Packets Received - BUPRC (0x4400; RC)

This register counts the number of good (no errors) unicast packets received. This register does not count unicast packets received that fail to pass address filtering. This register does not count packets counted by the Missed Packet Count (MPC) register. Packets sent to the manageability engine are included in this counter.

This register is available to the firmware only.

| Field | Bit(s) | Initial Value | Description                         |
|-------|--------|---------------|-------------------------------------|
| BUPRC | 31:0   | 0x0           | Number of Unicast packets received. |

### 8.19.6 BMC Total Multicast Packets Received - BMPRC (0x4404; RC)

This register counts the same events as the MPRC register ([Section 8.18.28](#)) for the BMC usage. This register is available to the firmware only.

### 8.19.7 BMC Total Broadcast Packets Received - BBPRC (0x4408; RC)

This register counts the same events as the BPRC register ([Section 8.18.27](#)) for the BMC usage. This register is available to the firmware only.

### 8.19.8 BMC Total Unicast Packets Transmitted - BUPTC (0x440C; RC)

This register counts the number of unicast packets transmitted. This register is available to the firmware only.

| Field | Bit(s) | Initial Value | Description                            |
|-------|--------|---------------|----------------------------------------|
| BUPTC | 31:0   | 0x0           | Number of unicast packets transmitted. |

### **8.19.9 BMC Total Multicast Packets Transmitted - BMPTC (0x4410; RC)**

This register counts the same events as the *MPTC* register ([Section 8.18.58](#)) for the BMC usage. This register is available to the firmware only.

### **8.19.10 BMC Total Broadcast Packets Transmitted - BBPTC (0x4414; RC)**

This register counts the same events as the *BPTC* register ([Section 8.18.59](#)) for the BMC usage. This register is available to the firmware only.

### **8.19.11 BMC FCS Receive Errors - BCRERRS (0x4418; RC)**

This register counts the same events as the *CRCERRS* register ([Section 8.18.1](#)) for the BMC usage. This register is available to the firmware only.

### **8.19.12 BMC Alignment Errors - BALGNERRC (0x441C; RC)**

This register counts the same events as the *ALGNERRC* register ([Section 8.18.2](#)) for the BMC usage. This register is available to the firmware only.

### **8.19.13 BMC Pause XON Frames Received - BXONRXC (0x4420; RC)**

This register counts the same events as the *XONRXC* register ([Section 8.18.15](#)) for the BMC usage. This register is available to the firmware only.

### **8.19.14 BMC Pause XOFF Frames Received - BXOFFRXC (0x4424; RC)**

This register counts the same events as the *XOFFRXC* register ([Section 8.18.17](#)) for the BMC usage. This register is available to the firmware only.

### 8.19.15 BMC Pause XON Frames Transmitted - BXONTXC (0x4428; RC)

This register counts the same events as the *XONTXC* register ([Section 8.18.16](#)) for the BMC usage. This register is available to the firmware only.

### 8.19.16 BMC Pause XOFF Frames Transmitted - BXOFFTXC (0x442C; RC)

This register counts the same events as the *XOFFTXC* register ([Section 8.18.18](#)) for the BMC usage. This register is available to the firmware only.

### 8.19.17 BMC Single Collision Transmit Frames- BSCC (0x4430; RC)

This register counts the same events as the *SCC* register ([Section 8.18.6](#)) for the BMC usage. This register is available to the firmware only.

### 8.19.18 BMC Multiple Collision Transmit Frames - BMCC (0x4434; RC)

This register counts the same events as the *MCC* register ([Section 8.18.8](#)) for the BMC usage. This register is available to the firmware only.

## 8.20 Wake Up Control Register Descriptions

### 8.20.1 Wakeup Control Register - WUC (0x5800; R/W)

The *PME\_En* and *PME\_Status* bits of this register are reset when *LAN\_PWR\_GOOD* is 0b. When *AUX\_PWR* = 0b, these register bits also reset by de-asserting *PE\_RST\_N* and during a D3 to D0 transition.

| Field              | Bit(s) | Initial Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| APME               | 0      | 0b <sup>1</sup> | Advance Power Management Enable<br>If set to 1b, APM Wakeup is enabled.<br>If this bit is set and the <i>APMPME</i> bit is cleared, reception of a magic packet asserts the <i>WUS.MAG</i> bit but does not assert a PME.<br><b>Note:</b> Bit is reset on Power on reset only.                                                                                                                                                                                                                                                                                                                                                                       |
| PME_En             | 1      | 0b              | PME_En<br>This read/write bit is used by the software device driver to enable generation of a PME event without writing to the Power Management Control / Status Register ( <i>PMCSR</i> ) in the PCIe configuration space.<br>Note: Bit reflects value of <i>PMCSR.PME_En</i> bit when the bit in the <i>PMCSR</i> register is modified. However when value of <i>WUC.PME_En</i> bit is modified by software device driver, value is not reflected in the <i>PMCSR.PME_En</i> bit.<br><b>Note:</b> Bit is reset only on power-on reset When <i>AUX_PWR</i> = 0 bit is reset also on de-assertion of <i>PE_RST_N</i> and during D3 to D0 transition. |
| PME_Status (R/W1C) | 2      | 0b              | PME_Status<br>This bit is set when the I350 receives a wakeup event. It is the same as the <i>PME_Status</i> bit in the Power Management Control / Status Register ( <i>PMCSR</i> ). Writing a 1b to this bit clears also the <i>PME_Status</i> bit in the <i>PMCSR</i> .<br><b>Note:</b> Bit is reset only on power-on reset When <i>AUX_PWR</i> = 0 bit is reset also on de-assertion of <i>PE_RST_N</i> and during D3 to D0 transition.                                                                                                                                                                                                           |
| APMPME             | 3      | 0b <sup>1</sup> | Assert PME On APM Wakeup<br>If set to 1b, the I350 sets the <i>PME_Status</i> bit in the Power Management Control / Status Register ( <i>PMCSR</i> ) and asserts <i>PE_WAKE_N</i> and sends a <i>PM_PME</i> PCIe message when APM Wakeup is enabled ( <i>WUC.APME</i> = 1) and the I350 receives a matching Magic Packet.<br><b>Notes:</b><br>1. When <i>WUC.APMPME</i> is set <i>PE_WAKE_N</i> is asserted and a <i>PM_PME</i> message is sent even if <i>PMCSR.PME_En</i> is cleared.<br>2. Bit is reset on Power on reset only.                                                                                                                   |

1. Loaded from the EEPROM.

## 8.20.2 Wakeup Filter Control Register - WUFC (0x5808; R/W)

This register is used to enable each of the pre-defined and flexible filters for wakeup support. A value of 1b means the filter is turned on.; A value of 0b means the filter is turned off.

If the *NoTCO* bit is set, then any packet that passes the manageability packet filtering as described in [Section 10.3](#), does not cause a Wake Up event.

1. If the *RCTL.UPE* is set, and the EX bit is set also, any unicast packet wakes up the system.

## 8.20.3 Wakeup Status Register - WUS (0x5810; R/W1C)

This register is used to record statistics about all wakeup packets received. If a packet matches multiple criteria then multiple bits could be set. Writing a 1b to any bit clears that bit.

This register is not cleared when RST# is asserted. It is only cleared when LAN\_PWR\_GOOD is de-asserted or when cleared by the software device driver.

**Note:** If additional packets are received that match one of the wakeup filters, after the original wakeup packet is received, the WUS register is not updated with the new match detection until the register is cleared.

| Field             | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                           |

1. Bit is set only when flex filter match is detected and *WUFC.FLEX\_HQ* is 0.

## 8.20.4 Wakeup Packet Length - WUPL (0x5900; RO)

This register indicates the length of the first wakeup packet received. It is valid if one of the bits in the Wakeup Status register (WUS) is set. It is not cleared by any reset.

| Field    | Bit(s) | Initial Value | Description                                                                                                              |
|----------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------|
| LEN      | 11:0   | X             | Length of wakeup packet. (If jumbo frames are enabled and the packet is longer than 2047 bytes then this field is 2047.) |
| Reserved | 31:12  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                     |

## 8.20.5 Wakeup Packet Memory - WUPM (0x5A00 + 4\*n [n=0...31]; RO)

This register is read-only and it is used to store the first 128 bytes of the wakeup packet for software retrieval after system wakeup. It is not cleared by any reset.

| Field | Bit(s) | Initial Value | Description        |
|-------|--------|---------------|--------------------|
| WUPD  | 31:0   | X             | Wakeup Packet Data |

## 8.20.6 Proxying Filter Control Register - PROXYFC (0x5F60; R/W)

This register is used to enable each of the pre-defined and flexible filters for Proxying support. A value of 1b means the filter is turned on. A value of 0b means the filter is turned off.

If the *NoTCO* bit is set, then any packet that passes the manageability packet filtering as described in [Section 10.3](#), is not forwarded to management for protocol offload even if it passes one of the Proxying Filters.

| Field        | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |

1. If the *RCTL.UPE* is set, and the EX bit is set also, any unicast packet is sent to Management for proxying.

## 8.20.7 Proxying Status Register - PROXYS (0x5F64; R/W1C)

This register is used to record statistics about all Proxying packets received. If a packet matches multiple criteria then multiple bits could be set. Writing a 1b to any bit clears that bit.

This register is not cleared when RST# is asserted. It is only cleared when LAN\_PWR\_GOOD is de-asserted or when cleared by the software device driver.

**Note:** If additional packets are received that matches one of the wakeup filters, after the original wakeup packet is received, the *PROXYS* register is updated with the matching filters accordingly.

| Field             | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                              |

| Reserved          | 31:24  | 0b            | Reserved.<br>Write 0, ignore on read. |

1. Bit is set only when flex filter match is detected and *WUFC.FLEX\_HQ* is 0.

## 8.20.8 IP Address Valid - IPAV (0x5838; R/W)

The IP Address Valid indicates whether the IP addresses in the IP Address Table are valid.

| Field    | Bit(s) | Initial Value | Description                           |
|----------|--------|---------------|---------------------------------------|
| V40      | 0      | 0b            | IPv4 Address 0 Valid.                 |
| V41      | 1      | 0b            | IPv4 Address 1 Valid.                 |
| V42      | 2      | 0b            | IPv4 Address 2 Valid.                 |
| V43      | 3      | 0b            | IPv4 Address 3 Valid.                 |
| Reserved | 15:4   | 0x0           | Reserved.<br>Write 0, ignore on read. |
| V60      | 16     | 0b            | IPv6 Address 0 Valid.                 |
| Reserved | 31:17  | 0b            | Reserved.<br>Write 0, ignore on read. |

## 8.20.9 IPv4 Address Table - IP4AT (0x5840 + 8\*n [n=0...3]; R/W)

The IPv4 Address Table is used to store the four IPv4 addresses for the ARP/IPv4 Request packet and Directed IP packet wakeup.

| Field      | Bit(s) | Initial Value | Description                                                                                                                                    |
|------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| IP Address | 31:0   | X             | IPv4 Address n<br>Note: These registers are written in Big Endian order (LS byte is first on the wire and is the MS byte of the IPV4 Address). |

| Field     | Dword # | Address | Bit(s) | Initial Value | Description    |
|-----------|---------|---------|--------|---------------|----------------|
| IPV4ADDR0 | 0       | 0x5840  | 31:0   | X             | IPv4 Address 0 |
| IPV4ADDR1 | 2       | 0x5848  | 31:0   | X             | IPv4 Address 1 |
| IPV4ADDR2 | 4       | 0x5850  | 31:0   | X             | IPv4 Address 2 |
| IPV4ADDR3 | 6       | 0x5858  | 31:0   | X             | IPv4 Address 3 |

## 8.20.10 IPv6 Address Table - IP6AT (0x5880 + 4\*n [n=0...3]; R/W)

The IPv6 Address Table is used to store the IPv6 addresses for neighbor Discovery packet filtering and Directed IP packet wakeup.

| Field      | Bit(s) | Initial Value | Description                                                                                                                                                            |
|------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP Address | 31:0   | X             | IPv6 Address bytes 4*n+1:4*n +4<br>Note: These registers appear in Big Endian order (LS byte, LS address is first on the wire and is the MS byte of the IPV6 Address). |

| Field     | Dword # | Address | Bit(s) | Initial Value | Description                 |
|-----------|---------|---------|--------|---------------|-----------------------------|
| IPV6ADDR0 | 0       | 0x5880  | 31:0   | X             | IPv6 Address 0, bytes 1-4   |
|           | 1       | 0x5884  | 31:0   | X             | IPv6 Address 0, bytes 5-8   |
|           | 2       | 0x5888  | 31:0   | X             | IPv6 Address 0, bytes 9-12  |
|           | 3       | 0x588C  | 31:0   | X             | IPv6 Address 0, bytes 16-13 |

## 8.20.11 Flexible Host Filter Table Registers - FHFT (0x9000 - 0x93FC; RW)

Each of the 4 Flexible Host Filters Table registers (FHFT) contains a 128 byte pattern and a corresponding 128-bit mask array. If enabled, the first 128 bytes of the received packet are compared against the non-masked bytes in the FHFT register.

Each 128 byte filter is composed of 32 DW entries, where each 2 DWs are accompanied by an 8-bit mask, one bit per filter byte. When a bit in the 8-bit mask field is set the corresponding Byte in the filter is compared.

The 8 LSB bits of the last DW of each filter contains a length field defining the number of bytes from the beginning of the packet compared by this filter, the length field should be 8 bytes aligned value. If actual packet length is less than (length - 8) (length is the value specified by the length field), the filter fails. Otherwise, it depends on the result of actual byte comparison. The value should not be greater than 128.

**Note:** The length field must be 8 bytes aligned. For filtering packets shorter than 8 bytes aligned the values should be rounded up to the next 8 bytes aligned value, the hardware implementation compares 8 bytes at a time so it should get extra zero masks (if needed) until the end of the length value.

Bits 31:8 of the last DW of each filter also includes a Queueing field (refer to [Section 8.20.11.1](#)). When the I350 is in D0 state, the *WUFC.FLEX\_HQ* bit is set to 1, *MRQC.Multiple Receive Queues* = 010b or 000b and the packet matches the flex filter, the Queueing field defines the receive queue for the packet, priority of the filter and actions to be initiated.

|          |   |          |   |            |   |      |   |      |   |
|----------|---|----------|---|------------|---|------|---|------|---|
| 31       | 0 | 31       | 8 | 7          | 0 | 31   | 0 | 31   | 0 |
| Reserved |   | Reserved |   | Mask [7:0] |   | DW 1 |   | DW 0 |   |

|          |          |              |      |      |
|----------|----------|--------------|------|------|
| Reserved | Reserved | Mask [15:8]  | DW 3 | DW 2 |
| Reserved | Reserved | Mask [23:16] | DW 5 | DW 4 |
| Reserved | Reserved | Mask [31:24] | DW 7 | DW 6 |

....

|           |          |          |                |           |          |          |          |           |          |           |          |
|-----------|----------|----------|----------------|-----------|----------|----------|----------|-----------|----------|-----------|----------|
| <b>31</b> | <b>8</b> | <b>7</b> | <b>0</b>       | <b>31</b> | <b>8</b> | <b>7</b> | <b>0</b> | <b>31</b> | <b>0</b> | <b>31</b> | <b>0</b> |
| Reserved  | Reserved | Reserved | Mask [119:112] | DW 29     | DW 28    |          |          |           |          |           |          |
| Queueing  | Length   | Reserved | Mask [127:120] | DW 31     | DW 30    |          |          |           |          |           |          |

Accessing the *FHFT* registers during filter operation can result in a packet being mis-classified if the write operation collides with packet reception. It is therefore advised that the flex filters are disabled prior to changing their setup.

### 8.20.11.1 Flex Filter Queueing Field

Queueing field resides in bits 31:8 of last DW (DW 63) of flex filter. The queueing field defines the receive queue to forward the packet (*RQUEUE*), the filter priority (*FLEX\_PRIO*) and additional filter actions. Operations defined in queueing field are enabled when the I350 is in D0 state, *MRQC.Multiple Receive Queues* = 010b or 000b, *WUFC.FLEX\_HQ* is 1 and relevant *WUFC.FLX[n]* bit is set.

| Field               | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                         |
|---------------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Length              | 7:0    | X             | Length<br>Filter Length in bytes. Should be 8 bytes aligned and not greater than 128 bytes.                                                                                                                                                                                         |
| RQUEUE              | 10:8   | X             | Receive Queue<br>Defines receive queue associated with this Flex filter. When match occurs in D0 state, packet is forwarded to the receive queue.                                                                                                                                   |
| Reserved            | 15:11  | X             | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                |
| FLEX_PRIO           | 18:16  | X             | Flex filter Priority<br>Defines the priority of the filter assuming two filters with same priority don't match. If two filters with the same priority match the incoming packet, the first filter (lowest address) is used in order to define the queue destination of this packet. |
| Reserved            | 23:19  | X             | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                |
| Immediate Interrupt | 24     | X             | Enables issuing an immediate interrupt when the Flex filter matches incoming packet.                                                                                                                                                                                                |
| Reserved            | 31:25  | X             | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                                                |

### 8.20.11.2 Flex Filter 0 - Example

| Field                  | Dword | Address | Bit(s) | Initial Value |

| Filter 0 Queueing      | 63    | 0x90FC  | 31:8   | X             |

### 8.20.12 Flexible Host Filter Table Extended Registers - FHFT\_EXT (0x9A00 - 0x9DFC; RW)

Each of the 4 additional Flexible Host Filters Table extended registers (FHFT\_EXT) contains a 128 Byte pattern and a corresponding 128-bit mask array. If enabled, the first 128 Bytes of the received packet are compared against the non-masked bytes in the FHFT\_EXT register. The layout and access rules of this table are the same as in FHFT.

## 8.21 Management Register Descriptions

All management registers are controlled by the remote BMC for both read and write. Host accesses to the management registers are blocked for write. The attributes for the fields in this chapter refer to the BMC access rights.

**Note:** All the registers described in this section can get their default values from EEPROM when manageability pass through works in legacy SMBus mode. The only exception being the MANC register where part of the bits are masked. The specific MANC bits that can be loaded from EEPROM are indicated in the register description.

### 8.21.1 Management VLAN TAG Value - MAVTV (0x5010 +4\*n [n=0...7]; RW)

Where “n” is the VLAN filter serial number, equal to 0,1,...7.

| Field    | Bit(s) | Initial Value | Description                                                                                                           |
|----------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------|
| VID      | 11:0   | 0x0           | Contains the VLAN ID that should be compared with the incoming packet if the corresponding bit in <i>MDEF</i> is set. |
| Reserved | 31:12  | 0x0           | Reserved<br>Write 0, ignore on read                                                                                   |

The *MAVTV* registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets as described in the Management chapter.

## 8.21.2 Management Flex UDP/TCP Ports - MFUTP (0x5030 + 4\*n [n=0...3]; RW)

Where each 32-bit register (n=0,...,3) refers to two UDP/TCP port filters (register at address offset n=0 refers to UDP/TCP ports 0 and 1, register at address offset n=1 refers to UDP/TCP ports 2 and 3, etc.).

| Field      | Bit(s) | Initial Value | Description                        |
|------------|--------|---------------|------------------------------------|
| MFUTP_even | 15:0   | 0x0           | 2*n Management Flex UDP/TCP port   |
| MFUTP_odd  | 31:16  | 0x0           | 2*n+1 Management Flex UDP/TCP port |

The *MFUTP* registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets. See [section 10.3](#).

Reset - The *MFUTP* registers are cleared on LAN\_PWR\_GOOD only. The initial values for this register can be loaded from the EEPROM after power-up reset.

**Note:** The *MFUTP\_even* and *MFUTP\_odd* fields should be written in network order.

## 8.21.3 Management Ethernet Type Filters- METF (0x5060 + 4\*n [n=0...3]; RW)

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                        |
|----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| METF     | 15:0   | 0x0           | EtherType value to be compared against the L2 EtherType field in the Rx packet.                                                                                                    |
| Reserved | 29:16  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                               |
| Polarity | 30     | 0b            | 0b = Positive filter - forward packets matching this filter to the manageability block.<br>1b = Negative filter - block packets matching this filter from the manageability block. |
| Reserved | 31     | 0b            | Reserved<br>Write 0, ignore on read.                                                                                                                                               |

The *METF* registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets. See [section 10.3](#).

Reset - The *METF* registers are cleared on LAN\_PWR\_GOOD only. The initial values for this register might be loaded from the EEPROM after power-up reset.

## 8.21.4 Management Control Register - MANC (0x5820; RW)

The *MANC* register can be written by the BMC and is not accessible to the host for writing.

| Field             | Bit(s)  | Initial Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|---------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved          | 13:0    | 0x0             | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| FW_RESET (R/W1C)  | 14      | 0b              | FW Reset occurred.<br>Set to 1b on a TCO Firmware Reset.<br>Cleared by write 1b.                                                                                                                                                                                                                                                                                                                                                                                               |
| TCO_Isolate (RO)  | 15      | 0b              | Set to 1 on a TCO Isolate command. When the "TCO_Isolate" bit is set. Host write cycles are completed successfully on the PCIe but silently ignored by internal logic.<br>Note that when FW initiates the TCO Isolate command it also initiates a FW interrupt via the <i>ICR.MNG</i> bit to the host and writes a value of 0x22 to the <i>FWSM.Ext_Err_Ind</i> field.<br>This bit is Read Only and mirrors the value of the Isolate bit in the internal Management registers. |
| TCO_RESET (R/W1C) | 16      | 0b              | TCO Reset occurred.<br>Set to 1b on a TCO Reset, to reset LAN port by BMC.<br>Cleared by write 1b.                                                                                                                                                                                                                                                                                                                                                                             |
| RCV_TCO_EN        | 17      | 0b <sup>1</sup> | TCO Receive Traffic Enabled.<br>When bit is set receive traffic to the manageability is enabled.<br>This bit should be set only if either the <i>MANC.EN_BMC2OS</i> or <i>MANC.EN_BMC2NET</i> bits are set.                                                                                                                                                                                                                                                                    |
| KEEP_PHY_LINK_UP  | 18      | 0b <sup>1</sup> | Block PHY reset and power state changes.<br>When this bit is set the PHY reset and power state changes do not effect the PHY. This bit can not be written to unless the <i>Keep_PHY_Link_Up_En</i> EEPROM bit is set.                                                                                                                                                                                                                                                          |
| Reserved          | 22:2019 | 0b              | Reserved.<br>Write 0 ignore on read.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| EN_XSUM_FILTER    | 23      | 0b <sup>1</sup> | Enable checksum filtering to MNG<br>When this bit is set, only packets that pass L3, L4 checksum are sent to the MNG block.                                                                                                                                                                                                                                                                                                                                                    |
| EN_IPv4_FILTER    | 24      | 0b <sup>1</sup> | Enable IPv4 address Filters – when set, the last 128 bits of the MIPAF register are used to store 4 IPv4 addresses for IPv4 filtering. When cleared, these bits store a single IPv6 filter.                                                                                                                                                                                                                                                                                    |
| FIXED_NET_TYPE    | 25      | 0b <sup>1</sup> | Fixed net type: If set, only packets matching the net type defined by the <i>NET_TYPE</i> field passes to manageability. Otherwise, both tagged and un-tagged packets can be forwarded to the manageability engine.                                                                                                                                                                                                                                                            |

| Field           | Bit(s) | Initial Value   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

1. Bit loaded from EEPROM in legacy SMBus mode.

## 8.21.5 Management Only Traffic Register - MNGONLY (0x5864; RW)

The MNGONLY register allows exclusive filtering of certain type of traffic to the BMC. Exclusive filtering enables the BMC to define certain packets that are forwarded to the BMC but not to the host. The packets will not be forwarded to the host even if they pass the host L2 filtering process.

Each manageability decision filter (*MDEF* and *MDEF\_EXT*) has a corresponding bit in the *MNGONLY* register. When a manageability decision filter (*MDEF* and *MDEF\_EXT*) forwards a packet to manageability, it may also block the packet from being forwarded to the host if the corresponding *MNGONLY* bit is set.

| Field            | Bit(s) | Initial Value <sup>1</sup> | Description                                                                                                                                                                                                                                         |
|------------------|--------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Exclusive to MNG | 7:0    | 0x0                        | Exclusive to MNG – when set, indicates that packets forwarded by the manageability filters to manageability are not sent to the host. Bits 0...7 correspond to decision rules defined in registers <i>MDEF</i> [0...7] and <i>MDEF_EXT</i> [0...7]. |
| Reserved         | 31:8   | 0x0                        | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                |

1. The initial values for this register can be loaded from the EEPROM after power-up reset or firmware reset.

## 8.21.6 Manageability Decision Filters- MDEF (0x5890 + 4\*n [n=0...7]; RW)

Where “n” is the decision filter

| Field         | Bit(s) | Initial Value <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                 |
|---------------|--------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Exact AND     | 3:0    | 0x0                        | Exact - Controls the inclusion of Exact MAC address 0 to 3<br>In the manageability filter decision (AND section). Bit 0 corresponds to exact MAC address 0 (MMAL0 and MMAH0), etc.                                                                                                                          |
| Broadcast AND | 4      | 0b                         | Broadcast - Controls the inclusion of broadcast address filtering in the manageability filter decision (AND section).                                                                                                                                                                                       |
| VLAN AND      | 12:5   | 0x0                        | VLAN - Controls the inclusion of VLAN tag 0 to 7 respectively<br>In the manageability filter decision (AND section). Bit 5 corresponds to VLAN tag 0, etc.                                                                                                                                                  |
| IPv4 Address  | 16:13  | 0x0                        | IPv4 Address - Controls the inclusion of IPV4 address 0 to 3 respectively in the manageability filter decision (AND section). Bit 13 corresponds to IPV4 address 0, etc.<br><b>Notes:</b><br>1. This field is relevant only if <i>MANC.EN_IPv4_FILTER</i> is set.<br>2. Supported only for Network traffic. |
| IPv6 Address  | 20:17  | 0b                         | IPv6 Address - Controls the inclusion of IPV6 address 0 to 3 respectively in the manageability filter decision (AND section). Bit 17 corresponds to IPV6 address 0, etc<br><b>Notes:</b><br>1. Bit 20 is relevant only if <i>MANC.EN_IPv4_FILTER</i> is cleared.<br>2. Supported only for Network traffic.  |
| Exact OR      | 24:21  | 0x0                        | Exact - Controls the inclusion of exact MAC address 0 to 3<br>In the manageability filter decision (OR section). Bit 21 corresponds to exact MAC address 0 (MMAL0 and MMAH0), etc.                                                                                                                          |
| Broadcast OR  | 25     | 0b                         | Broadcast - Controls the inclusion of broadcast address filtering in the manageability filter decision (OR section).                                                                                                                                                                                        |
| Multicast AND | 26     | 0b                         | Multicast - Controls the inclusion of Multicast address filtering in the manageability filter decision (AND section). Broadcast packets are not included by this bit.                                                                                                                                       |
| ARP Request   | 27     | 0b                         | ARP Request - Controls the inclusion of ARP Request filtering in the manageability filter decision (OR section).<br><b>Note:</b> Supported only for Network traffic.                                                                                                                                        |
| ARP Response  | 28     | 0b                         | ARP Response - Controls the inclusion of ARP Response filtering in the manageability filter decision (OR section).<br><b>Note:</b> Supported only for Network traffic.                                                                                                                                      |

| Field              | Bit(s) | Initial Value <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                                                                                            |

1. Default values are read from EEPROM.

## 8.21.8 Manageability IP Address Filter - MIPAF (0x58B0 + 4\*n [n=0...15]; RW)

The Manageability IP Address Filter register stores IP addresses for manageability filtering. The *MIPAF* register can be used in two configurations, depending on the value of the *MANC.EN\_IPv4\_FILTER* bit:

- *EN\_IPv4\_FILTER* = 0: the last 128 bits of the register store a single IPv6 address (*IPV6ADDR3*)
- *EN\_IPv4\_FILTER* = 1: the last 128 bits of the register store 4 IPv4 addresses (*IPV4ADDR[3:0]*)

*MANC.EN\_IPv4\_FILTER* = 0:

| DWORD# | Address | 31        | 0 |
|--------|---------|-----------|---|
| 0      | 0x58B0  | IPV6ADDR0 |   |
| 1      | 0x58B4  |           |   |
| 2      | 0x58B8  |           |   |
| 3      | 0x58BC  |           |   |
| 4      | 0x58C0  | IPV6ADDR1 |   |
| 5      | 0x58C4  |           |   |
| 6      | 0x58C8  |           |   |

1. The initial values for these registers can be loaded from the EEPROM after power-up reset. The registers are written by the BMC and not accessible to the host for writing.

Initial value:

| Field           | Bit(s) | Initial Value <sup>1</sup> | Description                                                                                                                                                                                                      |
|-----------------|--------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP_ADDR 4 bytes | 31:0   | X                          | 4 bytes of IP (v6 or v4) address.<br>i mod 4 = 0 to bytes 1 – 4<br>i mod 4 = 1 to bytes 5 – 8<br>i mod 4 = 0 to bytes 9 – 12<br>i mod 4 = 0 to bytes 13 – 16<br>where i div 4 is the index of IP address (0...3) |

1. The initial values for these registers can be loaded from the EEPROM after power-up reset. The registers are written by the BMC and not accessible to the host for writing.

Reset - The registers are cleared on LAN\_PWR\_GOOD only.

**Note:** These registers should be written in network order.

## 8.21.9 Manageability MAC Address Low - MMAL (0x5910 + 8\*n [n= 0...3]; RW)

Where “n” is the exact unicast/Multicast address entry, equal to 0...3.

| Field | Bit(s) | Initial Value <sup>1</sup> | Description                                                                      |
|-------|--------|----------------------------|----------------------------------------------------------------------------------|
| MMAL  | 31:0   | X                          | Manageability MAC Address Low. The lower 32 bits of the 48 bit Ethernet address. |

1. The initial values for these registers can be loaded from the EEPROM after power-up reset. The registers are written by the BMC and not accessible to the host for writing.

These registers contain the lower bits of the 48 bit Ethernet address. The *MMAL* registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets. See [section 10.3](#).

Reset - The *MMAL* registers are cleared on LAN\_PWR\_GOOD only. The initial values for this register can be loaded from the EEPROM after power-up reset.

**Note:** The *MMAL.MMAL* field should be written in network order.

### 8.21.10 Manageability MAC Address High - MMAH (0x5914 + 8\*n [n=0...3]; RW)

Where “n” is the exact unicast/Multicast address entry, equal to 0...3.

| Field    | Bit(s) | Initial Value <sup>1</sup> | Description                                                                       |
|----------|--------|----------------------------|-----------------------------------------------------------------------------------|
| MMAH     | 15:0   | X                          | Manageability MAC Address High. The upper 16 bits of the 48 bit Ethernet address. |
| Reserved | 31:16  | 0x0                        | Reserved. Write 0, ignore on read.                                                |

1. The initial values for these registers can be loaded from the EEPROM after power-up reset. The registers are written by the BMC and not accessible to the host for writing.

These registers contain the upper bits of the 48 bit Ethernet address. The complete address is {*MMAH*, *MMAL*}. The *MMAH* registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets. See [section 10.3](#).

Reset - The *MMAL* registers are cleared on LAN\_PWR\_GOOD only. The initial values for this register can be loaded from the EEPROM after power-up reset or firmware reset.

**Note:** The *MMAH.MMAH* field should be written in network order.

### 8.21.11 Flexible TCO Filter Table registers - FTFT (0x9400 - 0x94FC; RW)

The Flexible TCO Filter Table registers (*FTFT*) contains a 128 byte pattern and a corresponding 128-bit mask array. If enabled, the first 128 bytes of the received packet are compared against the non-masked bytes in the *FTFT* register.

The 128 byte filter is composed of 32 DW entries, where each 2 DWs are accompanied by an 8-bit mask, one bit per filter byte. The bytes in each 2 DWs are written in network order i.e. byte0 written to bits [7:0], byte1 to bits [15:8] etc. The mask field is set so that bit0 in the mask masks byte0, bit 1 masks byte 1 etc. A value of 1 in the mask field means that the appropriate byte in the filter should be compared to the appropriate byte in the incoming packet.

**Note:** The mask field must be 8 bytes aligned even if the length field is not 8 bytes aligned, as the hardware implementation compares 8 bytes at a time so it should get extra masks until the end of the next quad word. Any mask bit that is located after the length should be set to 0 indicating no comparison should be done.

In case the actual length which is defined by the length field register and the mask bits is not 8 bytes aligned there may be a case that a packet which is shorter then the actual required length passes the flexible filter. This may occur due to comparison of up to 7 bytes that come after the packet, but are not a real part of the packet.

The last DW of the filter contains a length field defining the number of bytes from the beginning of the packet compared by this filter. If actual packet length is less than length specified by this field, the filter fails. Otherwise, it depends on the result of actual byte comparison. The value should not be greater than 128.

The initial values for the *FTFT* registers can be loaded from the EEPROM after power-up reset. The *FTFT* registers are written by the BMC and are not accessible to the host for writing. The registers are used to filter manageability packets as described in [Section 10.3.3.5](#).

**Note:** The *FTFT* registers are cleared on LAN\_PWR\_GOOD and Firmware reset only.

|          |          |              |         |         |

## 8.22 Management-Host Interface Register Descriptions

The device driver of functions 0,1,2 and 3 communicates with the MMS block through CSR access. The manageability block is mapped to address 0x8800 -0x8FFF on the slave bus of each function.

### 8.22.1 Host Slave Command Interface to MMS

This interface is used by the device driver for several of commands and for delivering various types of data structure in both directions (MNG → Host, Host → MNG).

The address space is separated into two areas:

Direct access to the internal Management data ram: The internal DATA RAM is mapped to address 0x8800-0x8EFF. Writing to this address space goes directly to the RAM.

Control registers located at address 0x8F00.

#### 8.22.1.1 Host Slave Command I/F flow.

This interface is used for the external HOST software to access the MMS sub-system. The HOST software can write a command block or read data structure directly from the data ram. The HOST software controls these transactions through a slave access to the control register.

The flow below describes the process of initiating a command to the MMS:

1. The device driver takes ownership of the `SW_FW_SYNC.SW_MNG_SM` bit according to the flow described in [Section 4.7.1](#).
2. The device driver reads the `HICR` register and checks that the enable bit is set.
3. The device driver writes the relevant command block into the shared ram area.
4. The device driver sets the "command" bit in the control register. Setting this bit causes an interrupt to the Management.
5. The device driver polls the control register until the command bit is cleared by hardware.
6. When the MMS is done with the command it clears the command bit (if the MMS should reply with a data, it should clear the bit only after the data is in the ram area where the device driver can read it).
7. If the device driver reads control register and the "SV" bit is set, it means that there is a valid status of the last command in the RAM. If the "SV" is not set it means that the command has failed with no status in the RAM.

### 8.22.1.2 HOST Interface Control Register - HICR (0x8F00; RW)

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                  |
|----------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| En (RO)  | 0      | 0b            | Enable. When set it indicates that a RAM area is provided for device driver accesses.<br>This bit is read only for the device driver.                                                                                                                        |
| C        | 1      | 0b            | Command. The device driver sets this bit when it has finished putting a command block in the Management internal data ram. This bit should be cleared by the firmware after the command's processing has been completed.                                     |
| SV (RO)  | 2      | 0b            | Status Valid. Indicates that there is a valid status in CSR area that the device driver can read.<br>1b – status valid.<br>0b – status not valid.<br>The value of the bit is valid only when the C bit is cleared.<br>Only the device driver reads this bit. |
| Reserved | 31:3   | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                                                                         |

## 8.22.2 General Manageability HOST CSR Registers

| Field        | Bit(s) | Initial Value | Description                                                                                                                                                                                                 |
|--------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FWSW (RO)    | 15:0   | 0x0           | Firmware Status word<br>This bit is read only through the HOST interface.                                                                                                                                   |
| Reserved     | 30:16  | 0x0           | Reserved<br>Write 0, ignore on read.                                                                                                                                                                        |
| FWRI (R/W1C) | 31     | 1b            | Firmware Reset Indication.<br>Set when firmware reset is asserted. Cleared when HOST writes 1b to it. Writing 0b to this bit does not change its value.<br>Note: This bit is also set after LAN_POWER_GOOD. |

## 8.23 Memory Error Registers Description

Main internal memories are protected by error correcting code (ECC) or parity bits. The I350 contains several registers that enable and report detection of internal memory errors. Description and usage of these registers can be found in [Section 7.6](#).

## 8.23.1 Parity Error Indication- PEIND (0x1084; RC)

| Field                         | Bit(s) | Initial Value | Description                                                                            |
|-------------------------------|--------|---------------|----------------------------------------------------------------------------------------|
| lanport_parity_fatal_ind (RC) | 0      | 0b            | Fatal Error detected in LAN port Memory.<br>Bit is latched high and cleared on read.   |
| mng_parity_fatal_ind (RC)     | 1      | 0b            | Fatal Error detected in Management Memory.<br>Bit is latched high and cleared on read. |
| pcie_parity_fatal_ind (RC)    | 2      | 0b            | Fatal Error detected in PCIe Memory.<br>Bit is latched high and cleared on read.       |
| dma_parity_fatal_ind (RC)     | 3      | 0b            | Fatal Error detected in DMA Memory.<br>Bit is latched high and cleared on read.        |
| Reserved                      | 31:4   | 0x0           | Reserved<br>Write 0 ignore on read.                                                    |

## 8.23.2 Parity and ECC Indication Mask – PEINDM (0x1088; RW)

| Field                    | Bit(s) | Initial Value | Description                                                                                                               |
|--------------------------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------|
| lanport_parity_fatal_ind | 0      | 1b            | When set and <i>PEIND.lanport_parity_fatal_ind</i> is set, enable interrupt generation by setting the <i>ICR.FER</i> bit. |
| mng_parity_fatal_ind     | 1      | 1b            | When set and <i>PEIND.mng_parity_fatal_ind</i> is set, enable interrupt generation by setting the <i>ICR.FER</i> bit.     |
| pcie_parity_fatal_ind    | 2      | 1b            | When set and <i>PEIND.pcie_parity_fatal_ind</i> is set, enable interrupt generation by setting the <i>ICR.FER</i> bit.    |
| dma_parity_fatal_ind     | 3      | 1b            | When set and <i>PEIND.dma_parity_fatal_ind</i> is set, enable interrupt generation by setting the <i>ICR.FER</i> bit.     |
| Reserved                 | 31:4   | 0x0           | Reserved<br>Write 0 ignore on read.                                                                                       |

## 8.23.3 DMA Transmit Parity and ECC Control - DTPARC (0x3F00; RW)

| Field                | Bit(s) | Initial Value | Description                           |
|----------------------|--------|---------------|---------------------------------------|
| ram_dtx_iso_ecc_en   | 0      | 1b            | ram_dtx_iso ECC check enable.         |
| Reserved             | 1      | 0b            | Reserved.<br>Write 0, ignore on read. |
| ram_dtx_cntxt_ecc_en | 2      | 1b            | ram_dtx_cntxt ECC check enable.       |
| Reserved             | 3      | 0b            | Reserved.<br>Write 0, ignore on read. |

| Field                 | Bit(s) | Initial Value | Description                           |
|-----------------------|--------|---------------|---------------------------------------|
| Reserved              | 4:5    | 10b           | Reserved.<br>Write 0, ignore on read. |
| ram_dtx_temp_ecc_en   | 6      | 1b            | ram_dtx_temp ECC check enable.        |
| Reserved              | 7      | 0b            | Reserved.<br>Write 0, ignore on read. |
| ram_dtx_cmd_ecc_en    | 8      | 1b            | ram_dtx_cmd ECC check enable.         |
| Reserved              | 9      | 0b            | Reserved.<br>Write 0, ignore on read. |
| ram_dtx_dhrf_par_en   | 10     | 1b            | ram_dtx_dhrf parity check enable.     |
| Reserved              | 11     | 0b            | Reserved.<br>Write 0, ignore on read. |
| ram_dtx_icache_ecc_en | 12     | 1b            | ram_dtx_icache ECC check enable.      |
| Reserved              | 31:13  | 0x0           | Reserved.<br>Write 0, ignore on read. |

### 8.23.4 DMA Transmit Parity and ECC Status- DTPARS (0x3F10; R/W1C)

| Field             | Bit(s) | Initial Value | Description                                                                                                                                    |
|-------------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| ecc_ind_dtx_iso   | 0      | 0b            | dtx_iso memory ECC error indication<br><br>Indicates detection of correctable ECC error in ram if <i>DTPARC.ram_dtx_iso_ecc_en</i> is set.     |
| ecc_ind_dtx_cntxt | 1      | 0b            | dtx_cntxt memory ECC error indication<br><br>Indicates detection of correctable ECC error in ram if <i>DTPARC.ram_dtx_cntxt_ecc_en</i> is set. |
| Reserved          | 2      | 0b            | Reserved                                                                                                                                       |
| ecc_ind_dtx_temp  | 3      | 0b            | dtx_temp memory ECC error indication<br><br>Indicates detection of correctable ECC error in ram if <i>DTPARC.ram_dtx_temp_ecc_en</i> is set.   |
| ecc_ind_dtx_cmd   | 4      | 0b            | dtx_cmd memory ECC error indication<br><br>Indicates detection of correctable ECC error in ram if <i>DTPARC.ram_dtx_cmd_ecc_en</i> is set.     |

| Field              | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| par_ind_dtx_dhrf   | 5      | 0b            | <p>dtx_dhrf memory parity error indication</p> <p>Indicates detection of parity error in ram if <i>DTPARC.ram_dtx_dhrf_par_en</i> is set.</p> <p>When set stops all TX activity from the port. To recover from this condition Software Driver should issue a SW reset by asserting <i>CTRL.RST</i> and re-initializing the port.</p> <p>Will cause assertion of <i>PEIND.dma_parity_fatal_ind</i> and <i>ICR.FER</i> interrupt if bits are not masked.</p> <p><b>Note:</b></p> |

| DMACTHR       | 23:16  | 0x0           | DMA Coalescing Receive Threshold<br>This value defines the DMA coalescing Receive threshold in 1 Kilobyte units. When amount of data in internal receive buffer exceeds <i>DMACTHR</i> value, DMA coalescing is stopped and PCIe moves to L0 state.<br><b>Notes:</b><br>1. Value should be lower than <i>FCRTC.RTH_Coal</i> threshold value, to avoid needless generation of flow control packets when in DMA coalescing operating mode and flow control is enabled.<br>2. Receive threshold size should be smaller than internal receive buffer area reported in <i>IRPBS.RXPbsize</i> field.<br>3. If value is 0x0, condition to move out of DMA coalescing as a result of passing DMA Coalescing Receive Threshold is disabled.<br>4. Value programmed should be greater than Maximum packet size. |

## 8.24.4 DMA Coalescing Receive Packet Rate Threshold - DMCRTRH (0x5DD0;RW)

| Field       | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UTRESH      | 18:0   | 0x0           | Receive Traffic Threshold-size<br>Defines the minimum RX packet rate to activate DMA coalescing in 64 Byte chunks of data. RX packet rate below this value will not allow entry into DMA coalescing. Refer to <a href="#">Section 5.8</a> for additional information.<br><b>Notes:</b><br>1. Threshold is measured in 64 Byte chunks of data received during a time window defined by the port link speed (10Mbps, 100Mbps or 1Gbps), <i>SCCRL.INTERVAL</i> field and the time units defined in the <i>SCBI</i> register.<br>2. When amount of RX bytes received in the previous time window is below the value specified in the <i>DMCRTRH.UTRESH</i> field then DMA coalescing will not be entered in current time window.<br>3. When value of <i>UTRESH</i> field is 0x0, packet rate is not considered as a condition to enter or exit DMA coalescing state.<br>4. RX packet rate calculation includes both Network traffic to host and Host VF to VF traffic. |

1. Loaded from EEPROM.

## 8.25 Thermal Sensor Registers Description

Some of the thermal registers are read only and some of them are read write. Most values are loaded from the EEPROM but the BMC or Host may modify the settings.

The Thermal sensor registers are common to all functions. Before accessing any of the registers defined in this section Firmware or Software should take ownership of thermal Sensor semaphore bits (`SW_FW_SYNC.SW_PWRTS_SM` for software and `SW_FW_SYNC.FW_PWRTS_SM` for Firmware) according to the flow defined in [Section 4.7.1](#) and release ownership of the Thermal sensor semaphore bits according to the flow defined in [Section 4.7.2](#).

### 8.25.1 Thermal Sensor Measured Junction Temperature - THMJT (0x8100; RO)

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                              |
|----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tj       | 8:0    | X             | Measured Junction temperature<br>Measured junction temperature with 1°C resolution represented in 2's complement format.<br><b>Note:</b> Thermal Sensor precision +/-5°C.                                                                                                                |
| Reserved | 30:9   | 0x0           | Reserved<br>Write 0 ignore on read.                                                                                                                                                                                                                                                      |
| TH Valid | 31     | X             | Thermal Sensor Valid<br>When bit is set to 1b, thermal temperature indicated in the <code>THMJT.Tj</code> field is valid.<br><b>Note:</b> In Diagnostic operating mode when the <code>THMJT.Tj</code> temperature value is forced via the THDIAG register the TH Valid bit is set to 1b. |

## 8.25.2 Thermal Sensor Low Threshold Control - THLOWTC (0x8104; RW)

| Field      | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## 8.26 PHY Software Interface

### 8.26.1 Internal PHY Configuration - IPCNFG (0x0E38, RW)

The *IPCNFG* register controls PHY configuration.

| Field       | Bit(s) | Initial Value   | Description                                                                                                                                                                                                                                                                                                           | Mode |
|-------------|--------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| Reserved    | 0      |                 | Reserved                                                                                                                                                                                                                                                                                                              |      |
| MDI_Flip    | 0      | 0b <sup>1</sup> | MDI Flip<br>When set MDI Channel D is exchanged with MDI Channel A and MDI Channel C is exchanged with MDI Channel B.                                                                                                                                                                                                 | R/W  |
| 10BASE-TE   | 1      | 0b <sup>2</sup> | Enable low amplitude 10BASE-T operation<br>Setting this bit enables the I350 to operate in IEEE802.3az 10BASE-Te low power operation.<br>0b - 10BASE-Te operation disabled.<br>1b - 10BASE-Te operation enabled<br><br><b>Note:</b> When operating in 10BASE-T mode and bit is set supported cable length is reduced. | R/W  |
| EEE_100M_AN | 2      | 1b <sup>2</sup> | Report EEE 100M capability in Auto-negotiation<br>0b - Do not report EEE 100M capability in Auto-negotiation.<br>1b - Report EEE 100M capability in Auto-negotiation.<br><br><b>Note:</b> Changing value of bit causes link drop and re-negotiation.                                                                  | R/W  |

| Field     | Bit(s) | Initial Value   | Description                                                                                                                                                                                                                                | Mode |
|-----------|--------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| EEE_1G_AN | 3      | 1b <sup>2</sup> | Report EEE 1G capability in Auto-negotiation<br>0b - Do not report EEE 1G capability in Auto-negotiation.<br>1b - Report EEE 1G capability in Auto-negotiation.<br><b>Note:</b> Changing value of bit causes link drop and re-negotiation. | R/W  |
| Reserved  | 31:4   | 0x0             | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                      | R/W  |

1. Bit Loaded from *MDI\_Flip* bit in *Initialization Control 3* EEPROM word on power-up.

2. Loaded from EEPROM.

## 8.26.2 PHY Power Management - PHPM (0x0E14, RW)

The *PHPM* register controls Internal PHY Power management operation.

| Field                                | Bit(s) | Initial Value | Description                                                                                                                                                                                                                                                                                        | Mode   |
|--------------------------------------|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| SPD_EN <sup>1</sup>                  | 0      | 1b            | Smart Power Down<br>When set, enables PHY Smart Power Down mode.<br><b>Note:</b> Bit 3 in PHMIC (21d) register should be 0b to allow the <i>PHPM.SPD_EN</i> bit to disable Smart Power Down operation.                                                                                             | R/W    |
| Reserved                             | 0      |               | Reserved                                                                                                                                                                                                                                                                                           |        |
| D0LPLU                               | 1      | 0b            | D0 Low Power Link Up<br>When set, configures the PHY to negotiate for a low speed link in all states.<br><b>Note:</b> Bit 8 in <i>PHCTRL1</i> (23d) register should be 0b for the <i>PHPM.D0LPLU</i> bit to disable Low Power Link Up operation.                                                   | R/W    |
| LPLU <sup>2</sup>                    | 2      | 1b            | Low Power on Link Up<br>When set, enables the decrease in link speed while in non-D0a states when the power policy and power management state specify it.<br><b>Note:</b> Bit 8 in <i>PHCTRL1</i> (23d) register should be 0b for the <i>PHPM.LPLU</i> bit to disable Low Power Link Up operation. | R/W    |
| Disable 1000 in non-D0a <sup>3</sup> | 3      | 1b            | Disables 1000 Mb/s operation in non-D0a states.<br><b>Note:</b> Bit 0 in PHMIC (21d) register should be 0b to allow the <i>PHPM.Disable 1000 in non-D0a</i> bit to enable 1G operation in non-D0a PM state.                                                                                        | R/W    |
| Link Energy Detect                   | 4      | 0b            | This bit is set when the PHY detects energy on the link. Note that this bit is valid only if <i>PHPM.Go Link disconnect</i> is set to 1b.                                                                                                                                                          | RO, LH |
| Go Link disconnect                   | 5      | 0b            | Setting this bit will cause the PHY to enter link disconnect mode immediately.                                                                                                                                                                                                                     | R/W    |
| Disable 1000 <sup>4</sup>            | 6      | 0b            | When set, disables 1000 Mb/s in all power modes.<br><b>Note:</b> Bit 0 in PHMIC (21d) register should be 0b to allow the <i>PHPM.Disable 1000</i> bit to enable 1G operation.                                                                                                                      | R/W    |
| SPD_B2B_EN                           | 7      | 1b            | SPD back-to-back enable.<br><b>Note:</b> Bit 2 in PHMIC (21d) register should be 0b to allow the <i>PHPM.SPD_B2B_EN</i> bit to disable Smart Power Down Back to Back operation.                                                                                                                    | R/W    |
| rst_compl                            | 8      | 0b            | Indicates PHY internal reset cleared.                                                                                                                                                                                                                                                              | RO, LH |
| Disable 100 in non-D0a <sup>5</sup>  | 9      | 0b            | Disables 100 Mb/s and 1000 Mb/s operation in non-D0a states.                                                                                                                                                                                                                                       | R/W    |
| Reserved                             | 31:10  | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                                                                              | R/W    |

1. Bit Loaded from *SPD Enable* bit in *Initialization Control 4* EEPROM word on reset
2. Bit Loaded from *LPLU* bit in *Initialization Control 4* EEPROM word on reset
3. Bit Loaded from *Disable 1000 in non-D0a* bit in *Software Defined Pins Control* EEPROM word on reset
4. Bit Loaded from *Giga Disable* bit in *Software Defined Pins Control* EEPROM word on reset
5. Bit Loaded from *Disable 100 in non-D0a* bit in *Software Defined Pins Control* EEPROM word on reset

## 8.26.3 Internal PHY Software Interface (PHYREG)

1. Base Registers (0 through 10 and 15) are defined in accordance with the “Reconciliation Sub layer and Media Independent Interface” and “Physical Layer Link Signaling for 10/100/ 1000 Mb/s Auto-Negotiation” sections of the IEEE 802.3.
2. Additional registers (PHYREG.16 through 31) are defined in accordance with the IEEE 802.3 specification for adding unique chip functions.
3. Registers in [Table 8-24](#) are accessed using the internal MDIO interface via the MDIC register (Refer to [Section 3.7.2.2](#)).

**Table 8-24 Table of PHYREG Registers**

| Reset <sup>7</sup>                           | 15     | 1b = PHY reset.<br>0b = Normal operation.<br><b>Note:</b> When using PHY Reset, the PHY default configuration is not loaded from the EEPROM. The preferred way to reset the I350 PHY is using the CTRL.PHY_RST field. Refer to | WO, SC  | 0b      |

- Enables IEEE 802.3 Clause 22.2.4.1.9 collision test.
- This bit may be used to configure the link manually. Setting this bit has no effect unless address 0d, bit 12 is clear.
- Setting this bit isolates the PHY from the internal MII or GMII interfaces.
- When this bit is cleared, the link configuration is determined manually.
- The speed selection address 0d, bits 13 and 6 may be used to configure the link manually. Setting these bits has no effect unless address 0d bit 12 is clear.
- This is the master enable for digital and analog loopback as defined by the standard. The exact type of loopback is determined by the loopback control register (address 19d).
- The reset bit is automatically cleared upon completion of the reset sequence. This bit is set to 1 during reset.

### 8.26.3.2 PHY Status Register - PSTATUS (01d; RO)

| Field                                  | Bit(s) | Description                                                                                                                                                   | Mode     | Default |

1. Indicates that the PHY provides an extended set of capabilities that may be accessed through the extended register set. For a PHY that incorporates a GMII/RGMII, the extended register set consists of all management registers except registers 0, 1, and 15.
2. This bit indicates that a valid link has been established. Once cleared due to link failure, this bit remains cleared until register 1d is read via the management interface.
3. This bit indicates that a remote fault has been detected. Once set, it remains set until it is cleared by reading register 1d via the management interface or by PHY reset.
4. Upon completion of auto negotiation, this bit becomes set.

### 8.26.3.3 PHY Identifier Register 1 (LSB) - PHY ID 1 (02d; RO)

| Field                      | Bit(s) | Description                                                                                      | Mode | Default |
|----------------------------|--------|--------------------------------------------------------------------------------------------------|------|---------|
| PHY ID Number <sup>1</sup> | 15:0   | The PHY identifier composed of bits 3 through 18 of the Organizationally Unique Identifier (OUI) | RO   | 0x0154  |

1. PHY ID Number based on Intel assigned OUI number of 00-AA-00 following bit reversal.

### 8.26.3.4 PHY Identifier Register 2 (MSB) - PHY ID 2 (03d; RO)

| Field                          | Bit(s) | Description                                                  | Mode | Default |
|--------------------------------|--------|--------------------------------------------------------------|------|---------|
| Manufacturer's Revision Number | 3:0    | 4 bits containing the manufacturer's revision number.        | RO   | 0x0     |
| Manufacturer's Model Number    | 9:4    | 6 bits containing the manufacturer's part number.            | RO   | 0x3B    |
| PHY ID Number <sup>1</sup>     | 15:10  | The PHY identifier composed of bits 19 through 24 of the OUI | RO   | 0x0     |

1. PHY ID Number based on Intel assigned OUI number of 00-AA-00 following bit reversal.

### 8.26.3.5 Auto-Negotiation Advertisement Register - ANA (04d; R/W)

| Field                  | Bit(s) | Description                                                                                                                                                                                                               | Mode | Default |

| 11     | LP 1000T FD                            | 1b = Link Partner is capable of 1000BASE-T full duplex.<br>0b = Link Partner is not capable of 1000BASE-T full duplex.<br>Value in bit 11 are not valid until the ANE Register Page Received bit equals 1b. | RO         | 0b      |
| 12     | Remote Receiver Status                 | 1b = Remote Receiver OK.<br>0b = Remote Receiver Not OK.                                                                                                                                                    | RO         | 0b      |
| 13     | Local Receiver Status <sup>2</sup>     | 1b = Local Receiver OK.<br>0b = Local Receiver Not OK.                                                                                                                                                      | RO         | 0b      |
| 14     | Master/Slave Resolution <sup>3</sup>   | 1b = Local PHY configuration resolved to Master.<br>0b = Local PHY configuration resolved to Slave.<br>Value in bit 14 is not valid until the ANE Register Page Received bit equals 1b.                     | RO         | 0b      |
| 15     | Master/Slave Config Fault <sup>4</sup> | 1b = Master/Slave configuration fault detected.<br>0b = No Master/Slave configuration fault detected.                                                                                                       | RO, LH, SC | 0b      |

- These bits contain a cumulative count of the errors detected when the receiver is receiving idles and both local and remote receiver status are OK. The count is held at 255 in the event of overflow and is reset to zero by reading register 10d via the management interface or by reset.
- In the context of Energy Efficient Ethernet, during the Quiet periods, there is no signal transmitted to the line, hence the receiver will get no signal and will not be ready to receive (e.g. clock will be lost). This means that its local receiver status shall be set to NOT\_OK to convey the information, in this case, to the PMA PHY Control function, as is implied by Figure 40-15b of the IEEE Draft P802.3az-D2.3.
- This bit is not valid when bit 15 is set.
- Once set, this bit remains set until cleared by the following actions:
  - Read of register 10d via the management interface.
  - Reset.
  - Completion of auto negotiation.
  - Enable of auto negotiation

### 8.26.3.12 Extended Status Register - ESTATUS (15d; RO)

| Field                  | Bit(s) | Description                                                                      | Mode | Default |

| 1000BASE-T Half Duplex | 12     | 1b = 1000BASE-T half duplex capable.<br>0b = not 1000BASE-T half duplex capable. | RO   | 1b      |
| 1000BASE-T Full Duplex | 13     | 1b = 1000BASE-T full duplex capable.<br>0b = Not 1000BASE-T full duplex capable. | RO   | 1b      |
| 1000BASE-X Half Duplex | 14     | 1b = 1000BASE-X half duplex capable.<br>0b = Not 1000BASE-X half duplex capable. | RO   | 0b      |

| Field                  | Bit(s) | Description                                                                      | Mode | Default |
|------------------------|--------|----------------------------------------------------------------------------------|------|---------|
| 1000BASE-X Full Duplex | 15     | 1b = 1000BASE-X full duplex capable.<br>0b = Not 1000BASE-X full duplex capable. | RO   | 0b      |

### 8.26.3.13 Extended Memory Indirect Address Register - EMIADD (16d; R/W)

The *EMIADD* and *EMIDATA* registers enable indirect access to registers internal to the PHY at addresses greater than 31d. To read or write registers in the extended address space register address should be written to the *EMIADD* register and data should be written or read from the *EMIDATA* register.

| Field | Bit(s) | Description               | Mode | Default |
|-------|--------|---------------------------|------|---------|
| EADD  | 15:0   | Extended Register Address | R/W  | 0x0     |

### 8.26.3.14 Extended Memory Indirect Data Register - EMIDATA (17d; R/W)

| Field | Bit(s) | Description            | Mode | Default |
|-------|--------|------------------------|------|---------|
| EDATA | 15:0   | Extended Register Data | R/W  | 0x0     |

### 8.26.3.15 EEE MMD Extended Register support

Following Energy Efficient Ethernet (EEE) register bits defined in IEEE802.3az clause 45 are placed in extended PHY memory space and can be accessed using the *EMIADD* and *EMIDATA* registers.

Table 8-25 shows the mapping between the IEEE802.3az EEE MMD register bits and the registers inside the I350 PHY.

**Table 8-25 IEEE802.3az EEE PHY registers**

| MMD register | MMD Bits | Default | Name                           | Hex EMI Address | Comments                     |
|--------------|----------|---------|--------------------------------|-----------------|------------------------------|
| 3.0          | 10       | 1b      | Clock stoppable                | 0x182A          | Read on bit 0 of EMI address |
| 3.1          | 11       | 0b      | Tx LPI received (RO/LH)        | 0x182E          | Read on bit 3 of EMI address |
|              | 10       | 0b      | Rx LPI received (RO/LH)        |                 | Read on bit 2 of EMI address |
|              | 9        | 0b      | TX LPI indication (RO)         |                 | Read on bit 1 of EMI address |
|              | 8        | 0b      | RX LPI indication (RO)         |                 | Read on bit 0 of EMI address |
| 3.20         | 15:0     | 11b     | EEE capability register        | 0x0410          |                              |
| 3.22         | 15:0     | 0x0     | EEE wake error counter (RO/NR) | 0x4C08          | In 100BASE-TX mode           |
|              |          |         |                                | 0x4802          | In 1000BASE-T mode           |
| 7.60         | 1:0      | 11b     | EEE advertisement              | 0x040E          |                              |
| 7.61         | 1:0      | 00b     | EEE LP advertisement           | 0x040F          |                              |

In addition to the IEEE specified MMD registers tabulated above, the I350 PHY provides a single bit EMI register to force EEE mode for a 1000BASE-T or 100BASE-TX link. Since the IEEE802.3az specification mandates auto-negotiation for EEE, this register is intended for verification purposes only.

|  | Bits | Name           | Hex EMI Address | Comments                                                |
|--|------|----------------|-----------------|---------------------------------------------------------|
|  | 0    | eee_en_frc_emi | 040C            | forces the EEE mode for a 1000BASE-T or 100BASE-TX link |

### 8.26.3.16 PHY Control Register 2 - PHCTRL2(18d; R/W)

| Field                                 | Bit(s)          | Description                                                                                                                        | Mode | Default |
|---------------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------|------|---------|

| Reserved_1                            | 1               | Reserved.<br>Ignore on read, write 1.                                                                                              |      | 1b      |
| Enable Diagnostics <sup>1</sup>       | 2               | 1b = Enables diagnostics.<br>0b = Disables diagnostics.                                                                            | R/W  | 0b      |
| Reserved_1                            | 3               | Reserved.<br>Ignore on read, write 1.                                                                                              |      | 1b      |
| Reserved                              | 8:4             | Reserved.<br>Write 0, ignore on read.                                                                                              |      |         |
| MDI/MDI-X Configuration               | 9               | 1b = Manual MDI-X configuration.<br>0b = Manual MDI configuration.                                                                 | R/W  | 0b      |
| Automatic MDI/MDI-X                   | 10              | 1b = Enables automatic MDI/MDI-X detection.<br>0b = Disables automatic MDI/MDI-X detection.                                        | R/W  | 1b      |
| Reserved                              | 12:11           | Reserved.<br>Write 0, ignore on read.                                                                                              |      |         |
| Count Symbol Errors                   | 13 <sup>2</sup> | 1b = Rx error counter counts symbol errors.<br>0b = Rx error counter counts CRC errors.                                            | R/W  | 0b      |
| Count False Carrier Events            | 14 <sup>2</sup> | 1b = Rx error counter counts false carrier events.<br>0b = Rx error counter does not count false carrier events.                   | R/W  | 0b      |
| Resolve MDI/MDI-X before Forced Speed | 15              | 1b = Resolves MDI/MDI-X configuration before forcing speed.<br>0b = Does not resolve MDI/MDI-X configuration before forcing speed. | R/W  | 1b      |

1. This bit enables PHY diagnostics, which include IP phone detection and TDR cable diagnostics. It is not recommended to enable this bit in normal operation (when the link is active). This bit does not need to be set for link analysis cable diagnostics.
2. Count symbol errors (18.13) and count false carrier events (18.14) control the type of errors that the Rx error counter (20.15:0) counts (settings are shown below). The default is to count CRC errors (refer to [Table 8-26](#)).

**Table 8-26 RX Error Counter Programming**

| Count False Carrier Events | Count Symbol Errors | Rx Error Counter                               |
|----------------------------|---------------------|------------------------------------------------|
| 1                          | 1                   | Counts symbol errors and false carrier events. |
| 1                          | 0                   | Counts CRC errors and false carrier events     |
| 0                          | 1                   | Counts symbol errors.                          |
| 0                          | 0                   | Counts CRC errors.                             |

Bit 9, PHY Control Register 2, manually sets the MDI/MDI-X configuration if automatic MDIX is disabled, as indicated below.

**Table 8-27 MDI/MDI-X Configuration**

| Automatic MDI/MDI-X | MDI/MDI-X Configuration | MDI/MDI-X Mode                 |
|---------------------|-------------------------|--------------------------------|
| 1                   | X                       | Automatic MDI/MDI-X detection. |
| 0                   | 0                       | MDI configuration (NIC/DTE).   |
| 0                   | 1                       | MDI-X configuration (switch).  |

The mapping of the transmitter and receiver to pins, for MDI and MDI-X configurations for 10Base-T, 100Base-TX, and 1000Base-T is shown in Table 8-28. Note that even in manual MDI/MDI-X configuration, the PHY automatically detects and corrects for C and D pair swaps.

**Table 8-28 MDI/MDI-X Pin Mapping**

| Pin       | MDI Pin Mapping |              |                               | MDI-X Pin Mapping |              |                               |
|-----------|-----------------|--------------|-------------------------------|-------------------|--------------|-------------------------------|
|           | 10Base-T        | 100Base-TX   | 1000Base-T                    | 10Base-T          | 100Base-TX   | 1000Base-T                    |

### 8.26.3.17 Loopback Control Register - PHLBKC (19d; R/W)

| Field                          | Bit(s) | Description                                                                                                                                  | Mode | HW Rst |
|--------------------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| Force Link Status <sup>1</sup> | 0      | 1b = Forces link status okay in MII loopback.<br>0b = Forces link status not okay in MII loopback.                                           | R/W  | 1b     |
| Reserved                       | 5:1    | Reserved.<br>Write 0, ignore on read.                                                                                                        |      |        |
| Tx Suppression                 | 6      | 1b = Suppress Tx during all digital loopback.<br>0b = Do not suppress Tx during all digital loopback.                                        | R/W  | 1b     |
| External Cable                 | 7      | 1b = External cable loopback enabled.<br>0b = External cable loopback disabled.                                                              | R/W  | 0b     |
| Reserved_1                     | 8      | Reserved.<br>Write 1, ignore on read.                                                                                                        |      | 1b     |
| Remote                         | 9      | 1b = Remote loopback enabled.<br>0b = Remote loopback disabled.<br><b>Note:</b> When bit is set to 1b, PHY does not strip 10BASE-T preamble. | R/W  | 0b     |
| Line Driver                    | 10     | 1b = Line driver loopback selected.<br>0b = Line driver loopback not selected.                                                               | R/W  | 0b     |
| Reserved                       | 11     | Reserved.<br>Write 0, ignore on read.                                                                                                        |      |        |

| Field       | Bit(s) | Description                                                                    | Mode | HW Rst |
|-------------|--------|--------------------------------------------------------------------------------|------|--------|
| All Digital | 12     | 1b = All digital loopback selected.<br>0b = All digital loopback not selected. | R/W  | 1b     |
| Reserved    | 14:13  | Reserved.<br>Write 0, ignore on read.                                          |      |        |
| MII         | 15     | 1b = MII loopback selected.<br>0b = MII loopback not selected.                 | R/W  | 0b     |

1. This bit can be used to force link status okay during MII loopback. In MII loopback, the link status bit is not set unless force link status is used. In all other loopback modes, the link status bit is set when the link comes up.

### 8.26.3.17.1 Loopback Mode Setting

Table 8-29 shows how the loopback bit (0.14) and the LNK\_EN bit (23.13) should be set for each loopback mode. It also indicates whether the loopback mode sets the link status bit and when the PHY is ready to receive data.

**Table 8-29 Loopback Bit (0.14) Settings for Loopback Mode**

| Loopback    | Bit 0.14 = 1<br>Loopback Required | Bit 26.6<br>Link Status Set | PHY Ready for Data |
|-------------|-----------------------------------|-----------------------------|--------------------|
| MII         | Yes                               | 19.0                        | After a few ms     |
| All Digital | Yes                               | Yes                         | Link Status        |
| Line Driver | Yes                               | Yes                         | Link Status        |
| Ext Cable   | No                                | Yes                         | Link Status        |
| Remote      | No                                | Yes                         | Never              |

### 8.26.3.18 RX Error Counter Register - PHRERRC (20d; RO)

| Field                         | Bit(s) | Description                                                 | Mode   | Default |
|-------------------------------|--------|-------------------------------------------------------------|--------|---------|
| Rx Error Counter <sup>1</sup> | 15:0   | 16-bit Rx error counter.<br>This register is clear-on-read. | RO, SC | 0x0     |

1. Refer to Register 18d (bits 13 and 14) for error type descriptions.

### 8.26.3.19 Management Interface (MI) Control Register - PHMIC (21d; R/W)

| Field                            | Bit(s) | Description                                                                                                                                                                                                                                    | Mode | Default |
|----------------------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|---------|
| Auto Negotiation to 1000 disable | 0      | Disable auto-negotiation to 1000BASE-T.<br><b>Note:</b> Bit should be 0b to allow enabling 1G operation via the <i>PHPM.Disable 1000</i> and <i>PHPM.Disable 1000 in non-D0a</i> bits.                                                         | R/W  | 0b      |
| phy_in_nrg_pd                    | 1      | Energy Detect (Cable Disconnect) Status. When set it indicates that the PHY has entered the energy detect power-down mode because energy detect power-down is enabled and no energy has been detected on the line for 4s (cable disconnected). | RO   | x       |

| Field                           | Bit(s) | Description                                                                                                                                                                                                                                                                                                                                  | Mode | Default |
|---------------------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|---------|
| nrg_pd_tx_en                    | 2      | Software enable for periodic NLP transmission in energy detect power-down.<br>1b = Enables NLP transmission during energy-detect power down.<br>0b = Disables NLP transmission during energy-detect power down.<br><b>Note:</b> Bit should be 0b to allow the <i>PHPM.SPD_B2B_EN</i> bit to disable Smart Power Down Back to Back operation. | R/W  | 1b      |
| Energy Detect Power Down Enable | 3      | 1b = Enables energy detect power down.<br>0b = Disables energy detect power down<br><b>Note:</b> Bit should be 0b to allow the <i>PHPM.SPD_EN</i> bit to disable Smart Power Down operation.                                                                                                                                                 | R/W  | 1b      |
| Reserved                        | 15:4   | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                                                                                                                        |      |         |

### 8.26.3.20 PHY Configuration Register - PHCNFG (22d; R/W)

| Field                                       | Bit(s) | Description                                                                                                                                                                                       | Mode | Default |
|---------------------------------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|---------|
| Reserved                                    | 2:0    | Reserved.<br>Write 0, ignore on read.                                                                                                                                                             |      |         |
| Reserved_1                                  | 3      | Reserved.<br>Write 1, ignore on read.                                                                                                                                                             |      |         |
| Reserved                                    | 4      | Reserved.<br>Write 0, ignore on read.                                                                                                                                                             |      |         |
| Transmit Clock Enable                       | 5      | 1b = Enables output of mixer clock (transmit clock in 1000Base-T).<br>0b = Disables output.                                                                                                       | R/W  | 0b      |
| Group MDIO Mode Enable                      | 6      | When this bit is set, the PHY processes MDIO accesses to the group address 31 as if they are accesses to it's own PHY address.<br>1b = Enables group MDIO mode.<br>0b = Disables Group MDIO mode. | R/W  | 0b      |
| Alternate Next-Page                         | 7      | 1b = Enables manual control of 1000Base-T next pages only.<br>0b = Normal operation of 1000Base-T next page exchange.                                                                             | R/W  | 0b      |
| Reserved                                    | 9:8    | Reserved.<br>Write 11b, ignore on read.                                                                                                                                                           |      | 11b     |

| CRS Transmit Enable                         | 15     | 1b = Enables CRS on transmit in half-duplex mode.<br>0b = Disables CRS on transmit.                                                                                                               | R/W  | 0b      |

1. If automatic speed downshift is enabled and the PHY fails to auto negotiate at 1000Base-T, the PHY falls back to attempt connection at 100Base-TX and, subsequently, 10Base-T. This cycle repeats. If the link is broken at any speed, the PHY restarts this process by re-attempting connection at the highest possible speed (e.g., 1000Base-T).

### 8.26.3.21 PHY Control Register 1 - PHCTRL1 (23d; R/W)

| Field                                            | Bit(s) | Description                                                                                                                                                                                                                       | Mode    | Default |

1. When linking is disabled, the PHY automatically monitors for the appearance of a link partner and sets this bit if detected. Linking is disabled when LNK\_EN is cleared (23.13 = 0).
2. If LNK\_EN is set, the PHY attempts to bring up a link with a remote partner and will monitor the MDI for link pulses. If LNK\_EN is cleared the PHY takes down any active link, goes into standby, and does not respond to link pulses from a remote link partner. In standby, IP phone detect and TDR functions are available.
3. When this bit is set, the PHY performs automatic IP phone detection whenever linking is disabled. Linking is disabled when LNK\_EN is cleared (23.13 = 0). If an IP phone is detected it is indicated in 23.15.
4. When linking is disabled, the PHY automatically monitors for the appearance of a link partner and sets this bit if detected. Linking is disabled when LNK\_EN is cleared (23.13 = 0).

### 8.26.3.22 Interrupt Mask Register - PHINTM (24d; R/W)

| Field                          | Bit(s) | Description                                                 | Mode | Default |

### 8.26.3.23 Interrupt Status Register - PHINT (25d; RC)

The Interrupt Status Register reports interrupt conditions detected in the internal PHY. An interrupt bit that is set and is not masked via the *PHINTM* register will assert the *ICR.GPHY* bit and generate a Host interrupt if the bit is not masked. To clear the interrupt the Host should read the *PHINT* register before clearing the *ICR.GPHY* bit.

| Field                              | Bit(s) | Description                                              | Mode   | Default |

| TDR/IP Phone                   | 10     | 1b = Event has occurred.<br>0b = Event has not occurred. | RC, LH | 0b      |
| Reserved                       | 15:11  | Reserved.<br>Write 0, ignore on read.                    |        |         |

1. An event has occurred and the corresponding interrupt mask bit is enabled (set = 1).
2. If the management frame preamble is suppressed (MF preamble suppression, register 0, bit 6), it is possible for the PHY to lose synchronization if there is a glitch at the interface. The PHY can recover if a single frame with a preamble is sent to the PHY. The MDIO sync lost interrupt can be used to detect loss of synchronization and, thus, enable recovery.

### 8.26.3.24 PHY Status Register - PHSTAT (26d; RO)

| Field                                    | Bit(s) | Description                                                                                                   | Mode | Default |

| Auto negotiation Fault Status    | 14:13  | 11b = Reserved.<br>10b = Master/slave auto negotiation fault.<br>01b = Parallel detect auto negotiation fault.<br>00b = No auto negotiation fault. | RO   | 00b     |
| PHY in Standby Mode <sup>1</sup> | 15     | 1b = PHY in standby mode.<br>0b = PHY not in standby mode.                                                                                         | RO   | 0b      |

1. This bit indicates that the PHY is in standby mode and is ready to perform IP phone detection or TDR cable diagnostics. The PHY enters standby mode when LNK\_EN is cleared (23.13 = 0) and exits standby mode and attempts to auto negotiate a link when LNK\_EN is set (23.13 = 1).

### 8.26.3.25 Diagnostics Control Register (Linking Disabled) - PHDIAG (30d; R/W)

| Field                    | Bit(s) | Description                                                                                                                                                                                                                                    | Mode    | Default |
|--------------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|---------|
| Reserved                 | 9:0    | Reserved.<br>Write 0, ignore on read.                                                                                                                                                                                                          |         |         |
| TDR Rx Dim <sup>1</sup>  | 11:10  | Receive dimension for single-pair TDR analysis:<br>00b = TDR receive on pair A.<br>01b = TDR receive on pair B.<br>10b = TDR receive on pair C.<br>11b = TDR receive on pair D.                                                                | R/W     | 00b     |
| TDR Tx Dim <sup>2</sup>  | 13:12  | Transmit dimension for single-pair TDR analysis/first dimension to be reported for automatic TDR analysis:<br>00b = TDR transmit on pair A.<br>01b = TDR transmit on pair B.<br>10b = TDR transmit on pair C.<br>11b = TDR transmit on pair D. | R/W     | 00b     |
| TDR Request <sup>3</sup> | 15:14  | 11b = Automatic TDR analysis in progress.<br>10b = Single-pair TDR analysis in progress.<br>01b = TDR analysis complete, results valid.<br>00b = TDR analysis complete, results invalid.                                                       | R/W, SC | 00b     |

1. The TDR receive dimension is only valid for single-pair TDR analysis. It is ignored for automatic TDR analysis when all ten pair combinations are analyzed.
2. The TDR transmit dimension is only valid for single-pair TDR analysis. For automatic TDR analysis, these bits specify the first dimension to be reported in register 31.
3. Automatic TDR analysis is enabled by setting TDR request to {11}. All ten combinations of pairs are analyzed in sequence, and the results are available in register 31. TDR analysis for a single pair combination can be enabled by setting TDR request to {10}. Linking must be disabled (23.13 = 0) and IP phone detect must be disabled (23.14 = 0) to do TDR operations. Bit 15 self-clears when the TDR operation is complete. When TDR is complete, bit 14 indicates if the results are valid.

### 8.26.3.26 Diagnostics Status Register (Linking Disabled) - PHDSTAT (31d; RO)

)

| Field                                    | Bit(s) | Description                                                                                                                                                  | Mode | Default |

| Short Between Pairs X and C <sup>4</sup> | 12     | 1b = Short between pairs X and C.<br>0b = No short between pairs X and C.                                                                                    | RO   | 0b      |
| Short Between Pairs X and D <sup>4</sup> | 13     | 1b = Short between pairs X and D.<br>0b = No short between pairs X and D.                                                                                    | RO   | 0b      |
| TDR Fault Type Pair X <sup>5,6,7</sup>   | 15:14  | 11b = Result invalid.<br>10b = Open or short found on pair X.<br>01b = Strong impedance mismatch found on pair X.<br>00b = Good termination found on pair X. | RO   | 11b     |

- This indicates the pair to which the results in register bits 31.15:2 correspond.
- The first time this register is read after automatic TDR analysis has completed, it indicates the distance to the first fault on pair A. The second time it is read, it indicates the distance to the first fault on pair B; the third time, on pair C; and the fourth time, on pair D. It then cycles back to pair A. Pair indication bits 31.1:0 indicate to which pair the results correspond. Bits 30.13:12 can be used to specify a pair other than pair A as the first dimension to be reported.
- This 8-bit integer value is the distance in meters. The value 0xff indicates an unknown result.
- The first time these bits are read after automatic TDR analysis has completed, they indicate a short between pair A and pair A, B, C, and D, respectively. The second time they are read, they indicate a short between pair B and pair A, B, C, and D, respectively. The third time, with pair C; and the fourth time, with pair D. It then cycles back to pair A. Pair indication bits 31.1:0 indicate to which pair the results correspond. Bits 30.13:12 can be used to specify a pair other than pair A as the first dimension to be reported.
- The first time this register is read after automatic TDR analysis has completed, it indicates the fault type for pair A. The second time it is read, it indicates the fault type for pair B; the third, for pair C; and the fourth time, for pair D. It then cycles back to pair A. Pair indication bits 31.1:0 indicate pair to which the results correspond. Bits 30.13:12 can be used to specify a pair other than pair A as the first dimension to be reported.
- A value of 01b indicates either an open or a short. If 31.13:10 = 0000b, it is an open. For all other values of 31.13:10, each bit indicates a short to pair A, B, C and D.
- A value of 11 indicates that the results for this pair are invalid. An invalid result usually occurs when unexpected pulses are received during the TDR operation, e.g., from a remote PHY also doing TDR or trying to bring up a link. When an invalid result is indicated, the distance in bits 31.9:2 is 0xff and should be ignored.

1. When bit is set, the PHY detects the crossover of the received pair 2 (RJ-45 pins 4 and 5) and pair 3 (RJ-45 pins 7 and 8).

## 8.27 Virtual Function Device Registers

### 8.27.1 Queues Registers

Each VF has one queue – Q0. These queues are also used by the PF when working in non-IOV mode or if not all VFs are allocated to VMs. The mapping between the Virtual Queue number (VQn) and the Physical Queue number (PQn) is given by the equation: **PQn = VFn** (where VFn is the VF number).

For example: Q0 of VF0 is actually Q0, Q0 of VF1 are actually Q1, etc.

The virtual address of Q0 registers is always the same (RX: 0x2800, TX: 0x3800) – like the physical Q0 in the 82575 aliased area.

### 8.27.2 Non-Queue Registers

Non-queue registers get a virtual address that are equal to the same registers that belong to the PF. These registers are mapped to the physical address space at 0x10000, where each VM gets 0x100 bytes for its registers:

- VF0 registers: 0x10000 – 0x100FF
- VF1 registers: 0x10100 – 0x101FF
- ...

#### 8.27.2.1 EITR Registers

The I350 supports 25 EITR registers. In non IOV mode, all the EITR registers can be used by the PF. In IOV mode, 3 EITR registers are allocated to each VF and the PF should only use the remaining EITR registers. EITR0-2 registers are accessed by the VFs at addresses 0x1680 - 0x1688 and matches the PF EITRs according to the following table. EITR0 is always allocated to the PF.

| VF  | PF EITR         | Physical Address |
|-----|-----------------|------------------|
| 0   | EITR22 - EITR24 | 0x16D8 - 0x16E0  |
| 1   | EITR19 - EITR21 | 0x16CC - 0x16D4  |
| 2   | EITR16 - EITR18 | 0x16C0 - 0x16C8  |
| ... |                 |                  |
| 7   | EITR1 - EITR3   | 0x1684 - 0x168C  |

### 8.27.2.2 MSI-X Registers

The MSI-X vectors of each VF are reflected in its BAR3.

The PBA bits of the VFs are not replicated in the PF.

- Addresses in **Bold** indicates registers whose virtual addresses are different from their physical addresses due to the need to maintain a virtual address space of 16KBytes.
- Accesses through this addresses are executed as if accessed via the VF BAR.

## 8.27.4 Register Set - MSI-X BAR

| Virtual Address         | Physical Address Base (+ VF <sub>n</sub> * 0x30) | Abbreviation | Name                           |
|-------------------------|--------------------------------------------------|--------------|--------------------------------|
| 0x0000 - 0x0020         | 0x0010                                           | MSIXTADD     | MSIX table entry lower address |
| 0x0004 - 0x0024         | 0x0018                                           | MSIXTUADD    | MSIX table entry upper address |
| 0x0008 - 0x0028         | 0x0028                                           | MSIXTMSG     | MSIX table entry message       |
| 0x000C - 0x002C         | N/A                                              | MSIXTVCTRL   | MSIX table vector control      |
| Max (Page Size, 0x2000) | N/A                                              | MSIXPBA      | MSI-X Pending bit array        |

## 8.28 Virtual Function Register Descriptions

All the registers in this section are replicated per VF. The addresses are relative to the beginning of each VF address space. The address relative to BAR0 as programmed in the IOV structure in the PF configuration space (offset 0x180-0x184) can be found by the following formula:

$$\text{VF BAR0} + \text{Max}(16\text{K}, \text{system page size}) * \text{VF\#} + \text{CSR offset}.$$

Refer to [Section 8.28.49](#) for the list of registers exposed to the VF detailed below.

### 8.28.1 VT Control Register - VTCTRL (0x0000; WO)

| Field    | Bit(s) | Initial Value | Description                                                                                      |
|----------|--------|---------------|--------------------------------------------------------------------------------------------------|
| Reserved | 25:0   | 0x0           | Reserved.<br>Write 0, ignore on read.                                                            |
| RST (SC) | 26     | 0b            | VF Reset<br>This bit performs a reset of the queue enable and the interrupt registers of the VF. |
| Reserved | 31:27  | 0x0           | Reserved.<br>Write 0, ignore on read.                                                            |

### 8.28.2 VF Status Register - STATUS (0x0008; RO)

This register is a mirror of the PF status register. Refer to [Section 8.2.2](#) for details of this register.

### 8.28.3 VT Free Running Timer - VTFRTIMER (0x1048; RO)

This register reflects the value of a free running timer that can be used for various timeout indications. The register is reset by a PCI reset and/or software reset. This register is a mirror of the PF register. See description of this register in [Section 8.15.3](#).

### 8.28.4 VT Extended Interrupt Cause - VTEICR (0x1580; RC/W1C)

See description of this register in [Section 8.8.3](#).

| Field    | Bit(s) | Initial Value | Description                                              |
|----------|--------|---------------|----------------------------------------------------------|
| MSIX     | 2:0    | 0x0           | Indicates an interrupt cause mapped to MSI-X vectors 2:0 |
| Reserved | 31:3   | 0x0           | Reserved.<br>Write 0, ignore on read.                    |

## 8.28.5 VT Extended Interrupt Cause Set - VTEICS (0x1520; WO)

See the description of this register in [Section 8.8.4](#).

| Field    | Bit(s) | Initial Value | Description                                                |
|----------|--------|---------------|------------------------------------------------------------|
| MSIX     | 2:0    | 0x0           | Sets to corresponding <i>EICR</i> bit of MSI-X vectors 2:0 |
| Reserved | 31:3   | 0x0           | Reserved.<br>Write 0, ignore on read.                      |

## 8.28.6 VT Extended Interrupt Mask Set/Read - VTEIMS (0x1524; RWS)

See the description of this register in [Section 8.8.5](#).

| Field    | Bit(s) | Initial Value | Description                                                             |
|----------|--------|---------------|-------------------------------------------------------------------------|
| MSIX     | 2:0    | 0x0           | Set Mask bit for the corresponding <i>EICR</i> bit of MSI-X vectors 2:0 |
| Reserved | 31:3   | 0x0           | Reserved.<br>Write 0, ignore on read.                                   |

## 8.28.7 VT Extended Interrupt Mask Clear - VTEIMC (0x1528; WO)

See the description of this register in [Section 8.8.6](#).

| Field    | Bit(s) | Initial Value | Description                                                               |
|----------|--------|---------------|---------------------------------------------------------------------------|
| MSIX     | 2:0    | 0x0           | clear Mask bit for the corresponding <i>EICR</i> bit of MSI-X vectors 2:0 |
| Reserved | 31:3   | 0x0           | Reserved.<br>Write 0, ignore on read.                                     |

## 8.28.8 VT Extended Interrupt Auto Clear - VTEIAC (0x152C; RW)

See the description of this register in [Section 8.8.7](#).

| Field    | Bit(s) | Initial Value | Description                                                               |
|----------|--------|---------------|---------------------------------------------------------------------------|
| MSIX     | 2:0    | 0x0           | Auto clear bit for the corresponding <i>EICR</i> bit of MSI-X vectors 2:0 |
| Reserved | 31:3   | 0x0           | Reserved.<br>Write 0, ignore on read.                                     |

## 8.28.9 VT Extended Interrupt Auto Mask Enable - VTEIAM (0x1530; RW)

See the description of this register in [Section 8.8.8](#).

| Field    | Bit(s) | Initial Value | Description                                                              |
|----------|--------|---------------|--------------------------------------------------------------------------|
| MSIX     | 2:0    | 0x0           | Auto Mask bit for the corresponding <i>EICR</i> bit of MSI-X vectors 2:0 |
| Reserved | 31:3   | 0x0           | Reserved.<br>Write 0, ignore on read.                                    |

## 8.28.10 VT Interrupt Throttle - VTEITR (0x01680 + 4\*n[n = 0...2]; RW)

See the description of this register in [Section 8.8.14](#).

## 8.28.11 VT Interrupt Vector Allocation Registers - VTIVAR (0x1700; RW)

These registers define the allocation of the queue pair interrupt causes as defined in [Table 7-49](#) to one of the MSI-X vectors. Each *INT\_Alloc*[i] (i=0...3) field is a byte indexing an entry in the MSI-X Table Structure and MSI-X PBA Structure.

| Field            | Bit(s) | Initial Value | Description                                                                                                   |
|------------------|--------|---------------|---------------------------------------------------------------------------------------------------------------|
| INT_Alloc[0]     | 1:0    | X             | Defines the MSI-X vector assigned to the interrupt cause associated with queue 0 Rx. Valid values are 0 to 2. |
| Reserved         | 6:2    | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                         |
| INT_Alloc_val[0] | 7      | 0b            | Valid bit for INT_Alloc[0]                                                                                    |
| INT_Alloc[1]     | 9:8    | X             | Defines the MSI-X vector assigned to the interrupt cause associated with queue 0 Tx. Valid values are 0 to 2. |
| Reserved         | 14:10  | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                         |
| INT_Alloc_val[1] | 15     | 0b            | Valid bit for INT_Alloc[1]                                                                                    |
| Reserved         | 31:16  | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                         |

## 8.28.12 VT Interrupt Vector Allocation Registers - VTIVAR\_MISC (0x1740; RW)

This register defines the MSI-X vector allocated to the mailbox interrupt.

A mailbox interrupt is asserted in the VF upon reception of a mailbox message or an acknowledge from the PF.

| Field            | Bit(s) | Initial Value | Description                                                                                                    |
|------------------|--------|---------------|----------------------------------------------------------------------------------------------------------------|
| INT_Alloc[2]     | 1:0    | X             | Defines the MSI-X vector assigned to the interrupt cause associated with the mailbox. Valid values are 0 to 2. |
| Reserved         | 6:2    | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                          |
| INT_Alloc_val[2] | 7      | 0b            | Valid bit for INT_Alloc[2]                                                                                     |
| Reserved         | 31:8   | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                          |

### 8.28.13 MSI—X Table Entry Lower Address - MSIXTADD (BAR3: 0x0000 + 16\*n [n=0...2]; R/W)

Refer to [Section 8.9.1](#) for information about this register.

### 8.28.14 MSI—X Table Entry Upper Address - SIXTUADD (BAR3: 0x0004 + 16\*n [n=0...2]; R/W)

Refer to [Section 8.9.2](#) for information about this register.

### 8.28.15 MSI-X Table Entry Message - MSIXTMSG (BAR3: 0x0008 + 16\*n [n=0...2]; R/W)

Refer to [Section 8.9.3](#) for information about this register.

### 8.28.16 MSI-X Table Entry Vector Control - MSIXTVCTRL (BAR3: 0x000C + 16\*n [n=0...2]; R/W)

Refer to [Section 8.9.4](#) for information about this register.

### 8.28.17 MSI-X Pending Bits - MSIXPBA (BAR3: 0x2000; RO)

| Field        | Bit(s) | Initial Value | Description                                                                                                                                                                     |
|--------------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pending Bits | 2:0    | 0x0           | For each pending bit that is set, the function has a pending message for the associated MSI-X Table entry. Pending bits that have no associated MSI-X table entry are reserved. |
| Reserved     | 31:3   | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                                                                           |

**Note:** If a page size larger than 8K is programmed in the IOV structure, the address of the MSIX PBA table moves to be page aligned.

### 8.28.18 MSI-X PBA Clear - PBACL (0x0F04; R/W1C)

| Field    | Bit(s) | Initial Value | Description                                                                                                                                                            |
|----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PENBIT   | 2:0    | 0x0           | MSI-X Pending bits Clear<br>Writing a 1b to any bit clears the corresponding MSIXPBA bit; writing a 0b has no effect.<br>Reading this register returns the PBA vector. |
| Reserved | 31:3   | 0x0           | Reserved.<br>Write 0, ignore on read.                                                                                                                                  |

### 8.28.19 Receive Descriptor Base Address Low - RDBAL (0x2800; RW)

Refer to [Section 8.10.5](#) for information about this register.

### 8.28.20 Receive Descriptor Base Address High - RDBAH (0x2804; RW)

Refer to [Section 8.10.6](#) for information about this register.

### 8.28.21 Receive Descriptor Ring Length - RDLEN (0x2808; RW)

Refer to [Section 8.10.7](#) for information about this register.

### 8.28.22 Receive Descriptor Head - RDH (0x2810; RW)

Refer to [Section 8.10.8](#) for information about this register.

### **8.28.23 Receive Descriptor Tail - RDT (0x2818; RW)**

Refer to [Section 8.10.9](#) for information about this register.

### **8.28.24 Receive Descriptor Control - RXDCTL (0x2828; RW)**

Refer to [Section 8.10.10](#) for information about this register.

### **8.28.25 Split and Replication Receive Control Register queue - SRRCTL(0x280C; RW)**

Refer to [Section 8.10.2](#) for information about this register.

### **8.28.26 Receive Queue drop packet count - RQDPC (0x2830; RO)**

Refer to [Section 8.10.11](#) for information about this register.

### **8.28.27 Replication Packet Split Receive Type - PSRTYPE (0x0F0C; RW)**

Refer to [Section 8.10.3](#) for information about this register.

### **8.28.28 Transmit Descriptor Base Address Low - TDBAL (0x3800; RW)**

Refer to [Section 8.12.10](#) for information about this register.

### **8.28.29 Transmit Descriptor Base Address High - TDBAH (0x3804; RW)**

Refer to [Section 8.12.11](#) for information about this register.

### **8.28.30 Transmit Descriptor Ring Length - TDLEN (0x3808; RW)**

Refer to [Section 8.12.12](#) for information about this register.

### **8.28.31 Transmit Descriptor Head - TDH (0x3810; RW)**

Refer to [Section 8.12.13](#) for information about this register.

### **8.28.32 Transmit Descriptor Tail - TDT (0x3818; RW)**

Refer to [Section 8.12.14](#) for information about this register.

### **8.28.33 Transmit Descriptor Control - TXDCTL (0x3828; RW)**

Refer to [Section 8.12.15](#) for information about this register.

### **8.28.34 Transmit Queue drop packet count - TQDPC (0xE030 + 0x40\*n [n=0...7]; RO)**

Refer to [Section 8.12.18](#) for information about this register.

### **8.28.35 Tx Descriptor Completion Write-Back Address Low - TDWBAL (0x3838; RW)**

Refer to [Table 8.12.16](#) for information about this register.

### **8.28.36 Tx Descriptor Completion Write-Back Address High - TDWBAH (0x383C; RW)**

Refer to [Section 8.12.17](#) for information about this register.

### **8.28.37 Rx DCA Control Registers - RXCTL (0x2814; RW)**

Refer to [Section 8.13.1](#) for information about this register.

### **8.28.38 Tx DCA Control Registers - TXCTL (0x3814; RW)**

Refer to [Section 8.13.2](#) for information about this register.

### **8.28.39 Good Packets Received Count - VFGPRC (0x0F10; RO)**

Refer to [Section 8.18.77.1](#) for information about this register.

### **8.28.40 Good Packets Transmitted Count - VFGPTC (0x0F14; RO)**

Refer to [Section 8.18.77.2](#) for information about this register.

### **8.28.41 Good Octets Received Count - VFGORC (0x0F18; RO)**

Refer to [Section 8.18.77.3](#) for information about this register.

### **8.28.42 Good Octets Transmitted Count - VFGOTC (0x0F34; RO)**

Refer to [Section 8.18.77.4](#) for information about this register.

### **8.28.43 Multicast Packets Received Count - VFMPRC (0x0F38; RO)**

Refer to [Section 8.18.77.5](#) for information about this register.

### **8.28.44 Good TX Octets loopback Count - VFGOTLBC (0x0F50; RO)**

Refer to [Section 8.18.77.6](#) for information about this register.

### **8.28.45 Good TX packets loopback Count - VFGPTLBC (0x0F44; RO)**

Refer to [Section 8.18.77.7](#) for information about this register.

### **8.28.46 Good RX Octets loopback Count - VFGORLBC (0x0F48; RO)**

Refer to [Section 8.18.77.8](#) for information about this register.

### **8.28.47 Good RX Packets loopback Count - VFGPRLBC (0x0F40; RO)**

Refer to [Section 8.18.77.9](#) for information about this register.

### **8.28.48 Virtual Function Mailbox - VFMailbox (0x0C40; RW)**

Refer to [Section 8.14.3](#) for information about this register.

### **8.28.49 Virtualization Mailbox memory - VMBMEM (0x0800:0x083C; RW)**

A 64 bytes mailbox memory for PF and VF driver communication. Locations can be accessed as 32-bit or 64-bit words.

Refer to [Section 8.14.4](#) for information about this register.

§ §

## 9 PCIe\* Programming Interface

---

### 9.1 PCIe Compatibility

PCIe is completely compatible with existing deployed PCI software. To achieve this, PCIe hardware implementations conform to the following requirements:

- All devices required to be supported by deployed PCI software must be enumerable as part of a tree through PCI device enumeration mechanisms.
- Devices in their default operating state must conform to PCI ordering and cache coherency rules from a software viewpoint.
- PCIe devices must conform to PCI power management specifications and must not require any register programming for PCI-compatible power management beyond those available through PCI power management capabilities registers. Power management is expected to conform to a standard PCI power management by existing PCI bus drivers.
- PCIe devices implement all registers required by the PCI specification as well as the power management registers and capability pointers specified by the PCI power management specification. In addition, PCIe defines a PCIe capability pointer to indicate support for PCIe extensions and associated capabilities.

The I350 is a multi-function device with the following functions:

- LAN 0
- LAN 1
- LAN 2
- LAN 3

All functions contain the following regions of the PCI configuration space:

- Mandatory PCI configuration registers
- Power management capabilities
- MSI and MSI-X capabilities
- PCIe extended capabilities

Different parameters affect how LAN functions are exposed on the PCIe\*. [Table 9-1](#) describes the various mapping options.

**Table 9-1 I350 Function Mapping Options**

| Function Number | Function Description | Disable options                                                                                          |
|-----------------|----------------------|----------------------------------------------------------------------------------------------------------|
| 0 or 3          | LAN 0                | Strapping option                                                                                         |
| 1 or 0 or 2     | LAN 1                | Strapping option/ <i>Software Defined Pins Control</i> (Offset 0x20) EEPROM word in LAN1 section, bit 11 |
| 2 or 1 or 0     | LAN 2                | Strapping option/ <i>Software Defined Pins Control</i> (Offset 0x20) EEPROM word in LAN2 section, bit 11 |
| 3 or 0          | LAN 3                | Strapping option/ <i>Software Defined Pins Control</i> (Offset 0x20) EEPROM word in LAN3 section, bit 11 |

The mapping of each port to a PCIe function is influenced by the number of functions enabled, the dummy function mode selected and the function select word in the EEPROM. See [Section 4.4](#) for description of the function mapping when part of the functions are disabled.

## 9.2 Configuration Sharing Among PCI Functions

The I350 contains a single physical PCIe core interface. The I350 is designed so that each of the logical LAN ports appears as a distinct function. Many of the fields of the PCIe header space contain hardware default values that are either fixed or might be overridden by data from the EEPROM, but may not be independently specified for each function. The following fields are considered to be common to all LAN functions:

**Table 9-2 Common Fields for LAN Devices**

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Vendor ID                             | The Vendor ID of the I350 can be specified via EEPROM, but only a single value can be specified. The value is reflected identically for all functions. Default value is 0x8086.<br>The value is reflected identically for all LAN devices.                                                                                                                                                                                                                                                                                                                                                                                                |
| Revision                              | The revision number of the I350 is reflected identically for all LAN functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Header Type                           | This field indicates if a device is single function or multifunction. The value reflected in this field is reflected identically for all LAN functions, but the actual value reflected depends on LAN disable configuration.<br>When more than one I350 LAN function is enabled, all PCIe headers return 0x80 in this field, acknowledging being part of a multi-function device.<br>If only a single function is enabled, then a <i>single-function device</i> is indicated (this field returns a value of 0x00) and the LAN exists as device function 0 (when dummy mode is not enabled).<br>See <a href="#">Table 9-7</a> for details. |
| Subsystem ID                          | The subsystem ID of the I350 can be specified via EEPROM, but only a single value can be specified. The value is reflected identically for all LAN functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Subsystem Vendor ID                   | The I350 subsystem vendor ID can be specified via EEPROM, but only a single value can be specified. The value is reflected identically for all LAN functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Cap_Ptr,<br>Max Latency,<br>Min Grant | These fields reflect fixed values that are constant values reflected for all LAN functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

The following fields are implemented individually for each LAN function:

**Table 9-3 Fields Implemented Differently in LAN Devices**

|                                                  |                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Device ID                                        | The device ID reflected for each LAN function can be independently specified via EEPROM.                                                                                                                                                                                           |
| Command, Status                                  | Each LAN function implements its own command/status registers.                                                                                                                                                                                                                     |
| Latency Timer, Cache Line Size                   | Each LAN function implements these registers individually. The system should program these fields identically for each LAN to ensure consistent behavior and performance of the device.                                                                                            |
| Memory BAR, IO BAR, Expansion ROM BAR, MSI-X BAR | Each LAN function implements its own base address registers, enabling each function to claim its own address region(s).<br>The IO BAR and Flash BAR are supported depending on BAR32 setting in the EEPROM (See <a href="#">Section 9.4.11</a> ).                                  |
| Interrupt Pin                                    | Each LAN function independently indicates which interrupt pin (INTA#, INTB#, INTC# or INTD#) is used by that device's MAC to signal system interrupts. The value for each LAN device can be independently specified via EEPROM, but only if more than one LAN function is enabled. |
| Class Code                                       | Different class code values (iSCSI/LAN) can be set for each function.                                                                                                                                                                                                              |

See [Section 9.6.5](#) for a description of the configuration space reflected to virtual functions.

## 9.3 PCIe Register Map

### 9.3.1 Register Attributes

Configuration registers are assigned one of the attributes described in the following table.

**Table 9-4 Configuration Registers**

| Rd/Wr  | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RO     | Read-only register: Register bits are read-only and cannot be altered by software.                                                                                                                                                                                                                                                                                                                                                      |
| RW     | Read-write register: Register bits are read-write and can be either set or reset.                                                                                                                                                                                                                                                                                                                                                       |
| R/W1C  | Read-only status, write-1-to-clear status register, writing a 0b to R/W1C bits has no effect.                                                                                                                                                                                                                                                                                                                                           |
| ROS    | Read-only register with sticky bits: Register bits are read-only and cannot be altered by software. Bits are not cleared by reset and can only be reset with the PWRGOOD signal. Devices that consume AUX power are not allowed to reset sticky bits when AUX power consumption (either via AUX power or PME enable) is enabled.                                                                                                        |
| RWS    | Read-write register: Register bits are read-write and can be either set or reset by software to the desired state. Bits are not cleared by reset and can only be reset with the PWRGOOD signal. Devices that consume AUX power are not allowed to reset sticky bits when AUX power consumption (either via AUX power or PME enable) is enabled.                                                                                         |
| R/W1CS | Read-only status, write-1-to-clear status register: Register bits indicate status when read, a set bit indicating a status event can be cleared by writing a 1b. Writing a 0b to R/W1C bits has no effect. Bits are not cleared by reset and can only be reset with the PWRGOOD signal. Devices that consume AUX power are not allowed to reset sticky bits when AUX power consumption (either via AUX power or PME enable) is enabled. |
| HwInit | Hardware initialized: Register bits are initialized by firmware or hardware mechanisms such as pin strapping or serial EEPROM. Bits are read-only after initialization and can only be reset (for write-once by firmware) with PWRGOOD signal.                                                                                                                                                                                          |
| RsvdP  | Reserved and preserved: Reserved for future R/W implementations; software must preserve value read for writes to bits.                                                                                                                                                                                                                                                                                                                  |
| RsvdZ  | Reserved and zero: Reserved for future R/W1C implementations; software must use 0b for writes to bits.                                                                                                                                                                                                                                                                                                                                  |

The PCI configuration registers map is listed in [Table 9-5](#). Refer to a detailed description for registers loaded from the EEPROM at initialization time. Note that initialization values of the configuration registers are marked in parenthesis.

## 9.3.2 PCIe Configuration Space Summary

**Table 9-5 PCIe Configuration Registers Map - LAN functions**

| Section                     | Byte Offset | Byte 3                         | Byte 2                    | Byte 1                            | Byte 0                 |                |
|-----------------------------|-------------|--------------------------------|---------------------------|-----------------------------------|------------------------|----------------|
| Mandatory PCI register      | 0x0         | Device ID                      |                           |                                   | Vendor ID              |                |
|                             | 0x4         | Status Register                |                           |                                   | Control Register       |                |
|                             | 0x8         | Class Code (0x020000/0x010000) |                           |                                   |                        | Revision ID    |
|                             | 0xC         | BIST (0x00)                    | Header Type (0x0/0x80)    | Latency Timer                     | Cache Line Size (0x10) |                |
|                             | 0x10        | Base Address Register 0        |                           |                                   |                        |                |
|                             | 0x14        | Base Address Register 1        |                           |                                   |                        |                |

A description of the registers is provided in the following sections.

## 9.4 Mandatory PCI Configuration Registers

### 9.4.1 Vendor ID (0x0; RO)

This value can be loaded automatically from EEPROM address 0x0E at power up or reset. A value of 0x8086 is the default for this field at power up if the EEPROM does not respond or is not programmed. All functions are initialized to the same value.

**Note:** To avoid a system hang situation, if a value of 0xFFFF is read from the EEPROM, the value of the Vendor ID field defaults back to 0x8086.

## 9.4.2 Device ID (0x2; RO)

This is a read-only register. This field identifies individual I350 functions. It has the same default value for all LAN functions but can be auto-loaded from the EEPROM during initialization with a different value for each port. The following table describes the possible values according to the SKU and functionality of each function.

| PCI Function | Default Value | EEPROM Address   | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| LAN 2        | 0x151F        | 0xCD             | Same as port zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| LAN 3        | 0x151F        | 0x10D            | Same as port zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

1. Default ID for Embedded use and eeprom-less operation.

2. *CTRL\_EXT.Link\_Mode* field value 00b (10/100/1000 BASE-T internal PHY mode).

3. *CTRL\_EXT.Link\_Mode* field value 11b (SerDes).

4. *CTRL\_EXT.Link\_Mode* field value either 01b (1000BASE-KX) or 11b (SerDes - 1000BASE-BX). User option to enable Clause 37 Auto-negotiation.

5. *CTRL\_EXT.Link\_Mode* field value 10b (SGMII).

6. The Dummy function device ID is loaded from the *Dummy Device ID* EEPROM word and is used according to the disable status of the function. It is applicable only for function 0. See [section 6.2.7](#) for details.

## 9.4.3 Command Register (0x4; R/W)

This is a read/write register. Each function has its own command register. Unless explicitly specified, functionality is the same in all functions.

| Bit(s) | R/W              | Initial Value | Description                                                                                                     |
|--------|------------------|---------------|-----------------------------------------------------------------------------------------------------------------|
| 0      | R/W <sup>1</sup> | 0b            | I/O Access Enable<br>For LAN and Dummy functions this field is R/W.                                             |
| 1      | R/W              | 0b            | Memory Access Enable<br>For LAN and Dummy functions this field is R/W.                                          |
| 2      | R/W              | 0b            | Bus Master Enable (BME)<br>For LAN functions this field is R/W.<br>For Dummy function this field is RO as zero. |
| 3      | RO               | 0b            | Special Cycle Monitoring<br>Hardwired to 0b.                                                                    |
| 4      | RO               | 0b            | MWI Enable<br>Hardwired to 0b.                                                                                  |
| 5      | RO               | 0b            | Palette Snoop Enable<br>Hardwired to 0b.                                                                        |
| 6      | RW               | 0b            | Parity Error Response                                                                                           |
| 7      | RO               | 0b            | Wait Cycle Enable<br>Hardwired to 0b.                                                                           |

| Bit(s) | R/W | Initial Value | Description                                                                   |
|--------|-----|---------------|-------------------------------------------------------------------------------|
| 8      | RW  | 0b            | SERR# Enable                                                                  |
| 9      | RO  | 0b            | Fast Back-to-Back Enable                                                      |
| 10     | RW  | 0/1b          | Interrupt Disable <sup>2</sup><br>For Dummy function this field is RO as one. |
| 15:11  | RO  | 0x0           | Reserved                                                                      |

1. If IO\_Sup bit in PCIe Init Configuration 2 EEPROM Word (0x19) is 0, I/O Access Enable bit is RO with a value of 0. In EEPROM-less mode bit is R/W.
2. The Interrupt Disable register bit is a read-write bit that controls the ability of a PCIe device to generate a legacy interrupt message. When set, devices are prevented from generating legacy interrupt messages.

## 9.4.4 Status Register (0x6; RO)

Each function has its own status register. Unless explicitly specified, functionality is the same in all functions.

| Bits | R/W   | Initial Value | Description                                                                                                                                                                                                                                                                                                                      |
|------|-------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2:0  |       | 000b          | Reserved                                                                                                                                                                                                                                                                                                                         |
| 3    | RO    | 0b            | Interrupt Status <sup>1</sup>                                                                                                                                                                                                                                                                                                    |
| 4    | RO    | 1b            | New Capabilities<br>Indicates that a device implements extended capabilities. The I350 sets this bit, and implements a capabilities list, to indicate that it supports PCI power management, Message Signaled Interrupts (MSI), Enhanced Message Signaled Interrupts (MSI-X), Vital Product Data (VPD), and the PCIe extensions. |

| 14   | R/W1C | 0b            | Signaled System Error                                                                                                                                                                                                                                                                                                            |
| 15   | R/W1C | 0b            | Detected Parity Error                                                                                                                                                                                                                                                                                                            |

1. The *Interrupt Status* field is a RO field that indicates that an interrupt message is pending internally to the device.

## 9.4.5 Revision (0x8; RO)

The default revision ID of the I350 is 0x01. The value of the rev ID is a logic XOR between the default value and the value in EEPROM word 0x1E. Note that all LAN functions have the same revision ID.

**Note:** The default value is mirrored in the *MREVID.Step\_REV\_ID* internal register (Section 8.6.10).

## 9.4.6 Class Code (0x9; RO)

The class code is a RO hard coded value that identifies the I350's functionality.

- LAN 0...LAN3 - 0x020000/0x010000 - Ethernet/SCSI Adapter<sup>1</sup>
- Dummy Function - 0xFF0000 - Other device.

## 9.4.7 Cache Line Size (0xC; R/W)

This field is implemented by PCIe devices as a read-write field for legacy compatibility purposes but has no impact on any PCIe device functionality. Field is loaded from the *PCIe Init Configuration 3* (Word 0x1A) EEPROM word and defines cache line size in Dwords. All functions are initialized to the same value. In EEPROM-less systems, the value is 0x20.

## 9.4.8 Latency Timer (0xD; RO)

Not used. Hardwired to zero.

## 9.4.9 Header Type (0xE; RO)

This indicates if a device is single function or multifunction. If a single LAN function is the only active one then this field has a value of 0x00 to indicate a single function device. If other functions are enabled then this field has a value of 0x80 to indicate a multi-function device. The following table lists the different options to set the header type field:

**Table 9-7 Header Type Settings**

| LAN 0                                       | LAN 1                                     | LAN 2    | LAN 3    | Cross Mode Enable | Dummy Function Enable | Header Type Expected Value |
|---------------------------------------------|-------------------------------------------|----------|----------|-------------------|-----------------------|----------------------------|
| Disabled                                    | Disabled                                  | Disabled | Disabled | X                 | X                     | N/A (no function)          |
| Only one function enabled                   |                                           |          |          | X                 | 0                     | 0x00                       |
| More than one function is enabled           |                                           |          |          | X                 | X                     | 0x80 (multi function)      |
| Disabled                                    | At least on of functions 1 - 3 is enabled |          |          | 0                 | 1                     | 0x80 (dummy exist)         |
| At least one of functions 0 to 3 is enabled |                                           |          | Disabled | 1                 | 1                     | 0x80 (dummy exist)         |

## 9.4.10 BIST (0xF; RO)

BIST is not supported in the I350.

1. Selected according to bit 11, 12, 13 or 14 in *Device Rev ID* EEPROM word for LAN0, LAN 1, LAN2 or LAN3 respectively.

## 9.4.11 Base Address Registers (0x10...0x27; R/W)

The Base Address registers (BARs) are used to map I350 register space of the various functions. The I350 has a memory BAR, IO BAR and MSI-X BAR described in [Table 9-8](#) below.

**Table 9-8 Base Address Registers Description - LAN 0...3**

| Mapping Windows | Mapping Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Memory BAR      | The internal registers memories and external FLASH device are accessed as direct memory mapped offsets from the Base Address register. Software can access a Dword or 64 bits.<br>The FLASH space in this BAR is enabled by the FLSIZE and CSRSIZE fields in the BARCTRL register. Address 0 in the FLASH device is mapped to address 128K in the Memory BAR. When the usable FLASH size + CSR space is smaller than the memory BAR, then accessing addresses above the top of the FLASH wraps back to the beginning of the FLASH. |
| IO BAR          | All internal registers and memories can be accessed using I/O operations. There are two 4-byte registers in the IO mapping window: Addr Reg and Data Reg accessible as Dword entities. IO BAR support depends on the <i>IO_Sup</i> bit in the EEPROM "PCIe Init Configuration 2" word.                                                                                                                                                                                                                                             |
| MSI-X BAR       | The MSI-X vectors and Pending bit array (PBA) structures are accessed as direct memory mapped offsets from the MSI-X BAR. Software can access Dword entities.                                                                                                                                                                                                                                                                                                                                                                      |

### 9.4.11.1 32-bit LAN BARs Mode Mapping

This mapping is selected when bit 10 in the *Functions Control* EEPROM word is equal to 1b.

**Table 9-9 Base Address Setting in 32bit BARs Mode (BARCTRL.BAR32 = 1b)**

| BAR | Addr | 31                                                    | 5 | 4 | 3   | 2 | 1 | 0 |
|-----|------|-------------------------------------------------------|---|---|-----|---|---|---|
| 0   | 0x10 | Memory CSR + FLASH BAR (R/W - 31:17; RO - 16:4 (0x0)) |   |   | 0/1 | 0 | 0 | 0 |
| 1   | 0x14 | Reserved (read as all 0b's)                           |   |   |     |   |   |   |
| 2   | 0x18 | IO BAR (R/W - 31:5)                                   |   | 0 | 0   | 0 | 0 | 1 |
| 3   | 0x1C | MSI-X BAR (R/W - 31:14; RO - 13:4 (0x0))              |   |   | 0/1 | 0 | 0 | 0 |
| 4   | 0x20 | Reserved (read as all 0b's)                           |   |   |     |   |   |   |
| 5   | 0x24 | Reserved (read as all 0b's)                           |   |   |     |   |   |   |

### 9.4.11.2 64-bit LAN BARs Mode Mapping

This mapping is selected when bit 10 in the *Functions Control* EEPROM word is equal to 0b.

**Table 9-10 Base Address Setting in 64bit BARs Mode (BARCTRL.BAR32 = 0b)**

| BAR | Addr | 31                                                       | 5 | 4 | 3   | 2 | 1 | 0 |
|-----|------|----------------------------------------------------------|---|---|-----|---|---|---|
| 0   | 0x10 | Memory CSR + FLASH BAR Low (RW - 31:17; RO - 16:4 (0x0)) |   |   | 0/1 | 1 | 0 | 0 |
| 1   | 0x14 | Memory CSR + FLASH BAR High (RW)                         |   |   |     |   |   |   |
| 2   | 0x18 | IO BAR (R/W - 31:5)                                      |   | 0 | 0   | 0 | 0 | 1 |
| 3   | 0x1C | Reserved (RO - 0)                                        |   |   |     |   |   |   |
| 4   | 0x20 | MSI-X BAR Low (RW - 31:14; RO - 13:4 (0x0))              |   |   | 0/1 | 1 | 0 | 0 |
| 5   | 0x24 | MSI-X BAR High (RW)                                      |   |   |     |   |   |   |

### 9.4.11.3 Dummy Function BARs Mapping

| BAR | Addr | 31                          | 5 | 4 | 3   | 2 | 1 | 0 |
|-----|------|-----------------------------|---|---|-----|---|---|---|
| 0   | 0x10 | Dummy Memory (RO - 0x0)     |   |   | 0/1 | 0 | 0 | 0 |
| 1   | 0x14 | Reserved (read as all 0b's) |   |   |     |   |   |   |
| 2   | 0x18 | Reserved (read as all 0b's) |   |   |     |   |   |   |
| 3   | 0x1C | Reserved (read as all 0b's) |   |   |     |   |   |   |
| 4   | 0x20 | Reserved (read as all 0b's) |   |   |     |   |   |   |
| 5   | 0x24 | Reserved (read as all 0b's) |   |   |     |   |   |   |

### 9.4.11.4 Base Address Register Fields

All base address registers have the following fields.

**Table 9-11 Base Address Registers' Fields**

| Field                                                       | Bits | R/W | Description                                                                                                                                                                                            |
|-------------------------------------------------------------|------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mem / IO Space Indication                                   | 0    | RO  | 0b = Indicates memory space.<br>1b = Indicates I/O.                                                                                                                                                    |
| Memory Type                                                 | 2:1  | RO  | 00b = 32-bit BAR (BAR32 in the EEPROM equals 1b)<br>10b = 64-bit BAR (BAR32 in the EEPROM equals 0b)                                                                                                   |
| Prefetch Memory                                             | 3    | RO  | 0b = Non-prefetchable space.<br>1b = Prefetchable space.<br>This bit should be set only on systems that do not generate prefetchable cycles.<br>This bit is loaded from the PREFBAR bit in the EEPROM. |
| Address Space<br>(Low register for<br>64bit Memory<br>BARs) | 31:4 | R/W | The length of the RW bits and RO 0b bits depend on the mapping window sizes. Init value of the RW fields is 0x0.                                                                                       |
|                                                             |      |     | Mapping Window                                                                                                                                                                                         |
|                                                             |      |     | Memory CSR + FLASH BAR size depends on BARCTRL.FLSize and BARCTRL.CSRSize fields.                                                                                                                      |
|                                                             |      |     | MSI-X space is 16KB                                                                                                                                                                                    |
|                                                             |      |     | I/O spaces size is 32 bytes                                                                                                                                                                            |

### 9.4.12 CardBus CIS (0x28; RO)

Not used. Hardwired to zero.

### 9.4.13 Subsystem Vendor ID (0x2C; RO)

This value can be loaded automatically from EEPROM address 0x0C at power up or reset. A value of 0x8086 is the default for this field at power up if the EEPROM does not respond or is not programmed. All functions are initialized to the same value.

### 9.4.14 Subsystem ID (0x2E; RO)

This value can be loaded automatically from EEPROM address 0x0B at power up with a default value of 0x0000.

### 9.4.15 Expansion ROM Base Address (0x30; RW)

This register is used to define the address and size information for boot-time access to the optional Flash memory. Expansion ROM is enabled by placing 0b in the *LAN Boot Disable* EEPROM bit for LAN 0, LAN1, LAN2 and LAN 3, respectively. This register returns a zero value for functions without an expansion ROM window.

**Note:** For Dummy functions this register is Read Only with a value of zero.

| Field    | Bit(s) | R/W | Initial Value | Description                                                                                                                                                                                                                            |
|----------|--------|-----|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| En       | 0      | R/W | 0b            | 1b = Enables expansion ROM access.<br>0b = Disables expansion ROM access.                                                                                                                                                              |
| Reserved | 10:1   | RO  | 0b            | Always read as 0b. Writes are ignored.                                                                                                                                                                                                 |
| Address  | 31:11  | R/W | 0b            | Read-write bits are hard wired to 0b and dependent on the memory mapping window size. The LAN Expansion ROM spaces can be either 64 KB or up to 8 MB in powers of 2. Mapping window size is set by the <i>Flash Size</i> EEPROM field. |

### 9.4.16 Cap\_Ptr (0x34; RO)

The *Capabilities Pointer* field (Cap\_Ptr) is an 8-bit field that provides an offset in the device's PCI configuration space for the location of the first item in the Capabilities Linked List (CLL). The I350 sets this bit and implements a capabilities list to indicate that it supports PCI power management, Message Signaled Interrupts (MSIs), and PCIe extended capabilities. Its value is 0x40, which is the address of the first entry: PCI power management.

### 9.4.17 Interrupt Line (0x3C; RW)

Read/write register programmed by software to indicate which of the system interrupt request lines this I350's interrupt pin is bound to. See the PCIe definition for more details. Each of the PCIe functions has its own register.

For Dummy functions this register is RO - zero.

### 9.4.18 Interrupt Pin (0x3D; RO)

Read only register.

- LAN 0 / LAN 1/LAN2/ LAN3 <sup>1</sup> - A value of 0x1, 0x2, 0x3 or 0x4 indicates that this function implements legacy interrupt on INTA#, INTB#, INTC# or INTD#, respectively. Value is loaded from

---

1. If only a single device/function of the I350 component is enabled, this value is ignored and the *Interrupt Pin* field of the enabled device reports INTA# usage.

Initialization Control 3 (Offset 0x24) EEPROM words from relevant LAN 0, LAN 1, LAN2 and LAN3 EEPROM sections.

**Note:** If only a single port is enabled while the other ports are disabled, the enabled port uses INTA, independent of the EEPROM setting.

### 9.4.19 Max\_Lat/Min\_Gnt (0x3E; RO)

Not used. Hardwired to zero.

## 9.5 PCI Capabilities

The first entry of the PCI capabilities link list is pointed by the Cap\_Ptr register. The following tables describes the capabilities supported by the I350.

**Table 9-12 PCI capabilities for LAN functions**

| Address   | Item                                | Next Pointer           |
|-----------|-------------------------------------|------------------------|
| 0x40-47   | PCI Power Management                | 0x50                   |
| 0x50-67   | Message Signaled Interrupt          | 0x70                   |
| 0x70-8B   | Extended Message Signaled Interrupt | 0xA0                   |
| 0xA0-DB   | PCIe Capabilities                   | 0xE0/0x00 <sup>1</sup> |
| 0xE0-0xE7 | Vital Product Data Capability       | 0x00                   |

1. Next pointer is 0x00 if the VPD area in the EEPROM does not exist. In EEPROM-less mode, the PCIe capability is the last capabilities section.

**Table 9-13 PCI capabilities for Dummy function**

| Address | Item                 | Next Pointer |
|---------|----------------------|--------------|
| 0x40-47 | PCI Power Management | 0x50         |
| 0xA0-DB | PCIe Capabilities    | 0x00         |

### 9.5.1 PCI Power Management Capability

All fields are reset on full power-up. All of the fields except *PME\_En* and *PME\_Status* are reset on exit from D3cold state. If aux power is not supplied, the *PME\_En* and *PME\_Status* fields also reset on exit from D3cold state.

See the detailed description for registers loaded from the EEPROM at initialization time. Behavior of some fields in this section depend on the *Power Management* bit in EEPROM word 0x0A.

| Byte Offset | Byte 3                        | Byte 2                    | Byte 1                            | Byte 0               |
|-------------|-------------------------------|---------------------------|-----------------------------------|----------------------|
| 0x40        | Power Management Capabilities |                           | Next Pointer (0x50/<br>0xA0)      | Capability ID (0x01) |
| 0x44        | Data                          | Bridge Support Extensions | Power Management Control & Status |                      |

### 9.5.1.1 Capability ID (0x40; RO)

This field equals 0x01 indicating the linked list item as being the PCI Power Management registers.

### 9.5.1.2 Next Pointer (0x41; RO)

This field provides an offset to the next capability item in the capability list. In LAN function, a value of 0x50 points to the MSI capability. In the dummy function, a value of 0xA0 points to the PCI Express capability.

### 9.5.1.3 Power Management Capabilities - PMC (0x42; RO)

This field describes the I350's functionality at the power management states as described in the following table. Note that each device function has its own register.

| Bits               | Default                                   | R/W    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |           |               |       |                  |                      |        |                    |                     |        |                  |                             |        |

### 9.5.1.4 Power Management Control / Status Register - PMCSR (0x44; R/W)

This register is used to control and monitor power management events in the I350. Note that each device function has its own *PMCSR* register.

1. Loaded from EEPROM (See [Section 6.2.17](#)).

### 9.5.1.5 Bridge Support Extensions - PMCSR\_BSE (0x46; RO)

This register is not implemented in the I350. Values are set to 0x00.

### 9.5.1.6 Data Register (0x47; RO)

This optional register is used to report power consumption and heat dissipation. Reported register is controlled by the *Data\_Select* field in the PMCSR and the power scale is reported in the *Data\_Scale* field in the PMCSR. The data of this field is loaded from the EEPROM if power management is enabled in the EEPROM or with a default value of 0x00. The values for the I350 functions are read from EEPROM word 0x22.

| Function          | D0 (Consume/<br>Dissipate) | D3 (Consume/<br>Dissipate) | Common           |
|-------------------|----------------------------|----------------------------|------------------|
| PMCSR.Data_Select | 0x0 / 0x4                  | 0x3 / 0x7                  | 0x8              |
| Function 0        | EEPROM addr 0x22           | EEPROM addr 0x22           | EEPROM addr 0x22 |
| Functions 1 - 3   | EEPROM addr 0x22           | EEPROM addr 0x22           | 0x00             |

For other *Data\_Select* values, the Data register output is reserved (0x0).

## 9.5.2 MSI Configuration

This capability is not available for Dummy functions.

This structure is required for PCIe devices.

| Byte Offset | Byte 3                   | Byte 2 | Byte 1              | Byte 0               |
|-------------|--------------------------|--------|---------------------|----------------------|
| 0x50        | Message Control (0x0180) |        | Next Pointer (0x70) | Capability ID (0x05) |
| 0x54        | Message Address          |        |                     |                      |
| 0x58        | Message Upper Address    |        |                     |                      |
| 0x5C        | Reserved                 |        | Message Data        |                      |
| 0x60        | Mask bits                |        |                     |                      |
| 0x64        | Pending bits             |        |                     |                      |

### 9.5.2.1 Capability ID (0x50; RO)

This field equals 0x05 indicating the linked list item as being the MSI registers.

### 9.5.2.2 Next Pointer (0x51; RO)

This field provides an offset to the next capability item in the capability list. Its value of 0x70 points to the MSI-X capability structure.

### 9.5.2.3 Message Control (0x52; R/W)

The register fields are described in the following table. There is a dedicated register per PCI function to separately enable their MSI.

| Bits | Default         | R/W | Description                                                                                                                                                                               |
|------|-----------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | 0b              | R/W | MSI Enable<br>If set to 1b, equals MSI. In this case, the I350 generates an MSI for interrupt assertion instead of INTx signaling.                                                        |
| 3:1  | 000b            | RO  | Multiple Message Capable<br>The I350 indicates a single requested message per each function.                                                                                              |
| 6:4  | 000b            | RO  | Multiple Message Enable<br>The I350 returns 000b to indicate that it supports a single message per function.                                                                              |
| 7    | 1b              | RO  | 64-bit capable<br>A value of 1b indicates that the I350 is capable of generating 64-bit message addresses.                                                                                |
| 8    | 1b <sup>1</sup> | RO  | MSI per-vector masking.<br>A value of 1b indicates that the I350 is capable of per-vector masking.<br>This field is loaded from the <i>MSI-X Configuration</i> (Offset 0x16) EEPROM word. |
| 15:9 | 0b              | RO  | Reserved<br>Write 0 ignore on read.                                                                                                                                                       |

1. Default value is read from the EEPROM

### 9.5.2.4 Message Address Low (0x54; R/W)

Written by the system to indicate the lower 32 bits of the address to use for the MSI memory write transaction. The lower two bits always return 0b regardless of the write operation.

### 9.5.2.5 Message Address High (0x58; R/W)

Written by the system to indicate the upper 32-bits of the address to use for the MSI memory write transaction.

### 9.5.2.6 Message Data (0x5C; R/W)

Written by the system to indicate the lower 16 bits of the data written in the MSI memory write Dword transaction. The upper 16 bits of the transaction are written as 0b.

### 9.5.2.7 Mask Bits (0x60; R/W)

The Mask Bits and Pending Bits registers enable software to disable or defer message sending on a per-vector basis. As the I350 supports only one message, only bit 0 of these register is implemented.

| Bits | Default | R/W | Description                                                                    |
|------|---------|-----|--------------------------------------------------------------------------------|
| 0    | 0b      | R/W | MSI Vector 0 Mask<br>If set, the I350 is prohibited from sending MSI messages. |
| 31:1 | 000b    | RO  | Reserved                                                                       |

### 9.5.2.8 Pending Bits (0x64; R/W)

| Bits | Default | R/W | Description                                 |
|------|---------|-----|---------------------------------------------|
| 0    | 0b      | RO  | If set, the I350 has a pending MSI message. |
| 31:1 | 000b    | RO  | Reserved                                    |

## 9.5.3 MSI-X Configuration

More than one MSI-X capability structure per function is prohibited, but a function is permitted to have both an MSI and an MSI-X capability structure.

In contrast to the MSI capability structure, which directly contains all of the control/status information for the function's vectors, the MSI-X capability structure instead points to an MSI-X table structure and a MSI-X Pending Bit Array (PBA) structure, each residing in memory space.

Each structure is mapped by a Base Address Register (BAR) belonging to the function, located beginning at 0x10 in configuration space. A BAR Indicator Register (BIR) indicates which BAR, and a Qword-aligned offset indicates where the structure begins relative to the base address associated with the BAR. The BAR is permitted to be either 32-bit or 64-bit, but must map to memory space. A function is permitted to map both structures with the same BAR, or to map each structure with a different BAR.

The MSI-X table structure, listed in [Section 8.9](#), typically contains multiple entries, each consisting of several fields: message address, message upper address, message data, and vector control. Each entry is capable of specifying a unique vector.

The PBA structure, described in the same section, contains the function's pending bits, one per Table entry, organized as a packed array of bits within Qwords. Note that the last Qword might not be fully populated.

To request service using a given MSI-X table entry, a function performs a Dword memory write transaction using:

- The contents of the Message Data field entry for data.
- The contents of the Message Upper Address field for the upper 32 bits of the address.
- The contents of the Message Address field entry for the lower 32 bits of the address.

A memory read transaction from the address targeted by the MSI-X message produces undefined results.

The MSI-X table and MSI-X PBA are permitted to co-reside within a naturally aligned 4 KB address range, though they must not overlap with each other.

MSI-X table entries and Pending bits are each numbered 0 through N-1, where N-1 is indicated by the Table Size field in the MSI-X Message Control register. For a given arbitrary MSI-X table entry K, its starting address can be calculated with the formula:

$$\text{Entry starting address} = \text{Table base} + K * 16$$

For the associated Pending bit K, its address for Qword access and bit number within that Qword can be calculated with the formulas:

$$\text{Qword address} = \text{PBA base} + (K \text{ div } 64) * 8$$

$$\text{Qword bit\#} = K \text{ mod } 64$$

Software that chooses to read Pending bit K with Dword accesses can use these formulas:

$$\begin{aligned}\text{Dword address} &= \text{PBA base} + (\text{K} \div 32) * 4 \\ \text{Dword bit\#} &= \text{K} \bmod 32\end{aligned}$$

The I350 also supports the table-less MSI-X mode, where a single interrupt vector is provided. The MSI-X table and MSI-X PBA are not used. Instead, the capability structure includes several additional fields (Message Address, Message Address Upper, and Message Data) for vector configuration. The I350 embeds the number of the original MSI-X vectors (i.e. the vectors supported if the number of vectors was not limited to 1) in the LSB bits of the Message Data field.

**Table 9-14 MSI-X capability Structure**

| Byte Offset | Byte 3                    | Byte 2 | Byte 1              | Byte 0               |
|-------------|---------------------------|--------|---------------------|----------------------|
| 0x70        | Message Control (0x00090) |        | Next Pointer (0xA0) | Capability ID (0x11) |
| 0x74        | Table Offset              |        |                     |                      |
| 0x78        | PBA offset                |        |                     |                      |

This capability is not available for Dummy functions.

### 9.5.3.1 Capability ID (0x70; RO)

This field equals 0x11 indicating the linked list item as being the MSI-X registers.

### 9.5.3.2 Next Pointer (0x71; RO)

This field provides an offset to the next capability item in the capability list. Its value of 0xA0 points to the PCIe capability.

### 9.5.3.3 Message Control (0x72; R/W)

The register fields are described in the following table. There is a dedicated register per PCI function to separately configure their MSI-X functionality.

| Bits  | Default            | R/W | Description                                                                                                                                                                                                                                                                                                                                                                    |
|-------|--------------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10:0  | 0x009 <sup>1</sup> | RO  | TS - Table Size<br>System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1. For example, a returned value of 0x00F indicates a table size of 16.<br>The I350 supports 10 MSI-X vectors.<br>This field is loaded from the <i>MSI-X Configuration</i> (Offset 0x16) EEPROM word.                                                           |
| 13:11 | 000b               | RO  | Reserved<br>Always return 000b on read. Write operation has no effect.                                                                                                                                                                                                                                                                                                         |
| 14    | 0b                 | R/W | FM - Function Mask<br>If set to 1b, all of the vectors associated with the function are masked, regardless of their per-vector <i>Mask</i> bit states.<br>If set to 0b, each vector's <i>Mask</i> bit determines whether the vector is masked or not.<br>Setting or clearing the <i>MSI-X Function Mask</i> bit has no effect on the state of the per-vector <i>Mask</i> bits. |

| Bits | Default | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------|---------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15   | 0b      | R/W | En - MSI-X Enable<br>If set to 1b and the <i>MSI Enable</i> bit in the MSI Message Control (MMC) register is 0b, the function is permitted to use MSI-X to request service and is prohibited from using its INTx# pin.<br>System configuration software sets this bit to enable MSI-X. A software device driver is prohibited from writing this bit to mask a function's service request.<br>If set to 0b, the function is prohibited from using MSI-X to request service. |

1. Default value is read from the EEPROM

### 9.5.3.4 MSI-X Table Offset (0x74; R/W)

| Bits | Default | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|---------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:3 | 0x000   | RO   | Table Offset<br>Used as an offset from the address contained by one of the function's BARs to point to the base of the MSI-X table. The lower three table BIR bits are masked off (set to zero) by software to form a 32-bit Qword-aligned offset.                                                                                                                                                                                                                                               |
| 2:0  | 0x3/0x4 | RO   | Table BIR<br>Indicates which one of a function's BARs, located beginning at 0x10 in configuration space, is used to map the function's MSI-X table into memory space.<br>BIR values: 0...5 correspond to BARs 0x10...0x 24 respectively. A BIR value of 3 indicates that the table is mapped in BAR 3 (address 0x1C).<br>When <i>BARCTRL.BAR32</i> equals 0b (64 bit MMIO mapping) the table BIR equals 0x4. When <i>BARCTRL.BAR32</i> equals 1b (32 bit MMIO mapping) the table BIR equals 0x3. |

### 9.5.3.5 MSI-X Pending Bit Array - PBA Offset (0x78; R/W)

| Bits | Default | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|---------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:3 | 0x400   | RO   | PBA Offset<br>Used as an offset from the address contained by one of the function's BARs to point to the base of the MSI-X PBA. The lower three PBA BIR bits are masked off (set to zero) by software to form a 32-bit Qword-aligned offset.                                                                                                                                                                                                                                                                |
| 2:0  | 0x3     | RO   | PBA BIR: Indicates which one of a function's Base Address registers, located beginning at 10h in Configuration Space, is used to map the function's MSI-X PBA into Memory Space.<br>BIR values: 0...5 correspond to BARs 0x10...0x 24 respectively. A BIR value of 3 indicates that the table is mapped in BAR 3 (address 0x1C).<br>When <i>BARCTRL.BAR32</i> equals 0b (64 bit MMIO mapping) the table BIR equals 0x4. When <i>BARCTRL.BAR32</i> equals 1b (32 bit MMIO mapping) the table BIR equals 0x3. |

## 9.5.4 CSR Access Via Configuration Address Space

These registers are not available for Dummy functions.

### 9.5.4.1 IOADDR Register (0x98; R/W)

This is a read/write register. Each function has its own *IOADDR* register. Functionality is the same in all functions. Register is cleared at Power-up or PCIe reset.

**Note:** When function is in D3 state Software should not attempt to access CSRs via the *IOADDR* and *IOWDATA* registers.

| Bit(s) | R/W              | Initial Value | Description                                                                                                                                                                                                                                                                                                                                                   |
|--------|------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30:0   | R/W <sup>1</sup> | 0x0           | Internal Register or Internal Memory location Address.<br>0x00000-0x1FFFF – Internal Registers and Memories<br>0x20000-0x7FFFFFFF – Undefined                                                                                                                                                                                                                 |
| 31     | R/W              | 0b            | Configuration IO Access Enable.<br>0b - CSR configuration read or write disabled.<br>1b - CSR Configuration read or write enabled<br>When bit is set accesses to the IODATA register actually generate transactions to the device. Otherwise, accesses to the IODATA register are don't-cares (write are discarded silently, reads return arbitrary results). |

1. In the event that the *CSR\_conf\_en* bit in the *PCIe Init Configuration 2* EEPROM word is cleared, accesses to the *IOADDR* register via configuration address space is ignored and has no effect on the register and the CSRs referenced by the *IOADDR* register.

### 9.5.4.2 IODATA Register (0x9C; R/W)

This is a read/write register. Each function has its own *IODATA* register. Functionality is the same in all functions. Register is cleared at Power-up or PCIe reset.

| Bit(s) | R/W              | Initial Value | Description                                                                                                                                                                                 |
|--------|------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0   | R/W <sup>1</sup> | 0x0           | Data field for reads or writes to the Internal register or internal memory location as identified by the current value in <i>IOADDR</i> . All 32 bits of this register are read/write-able. |

1. In the event that the *CSR\_conf\_en* bit in the *PCIe Init Configuration 2* EEPROM word is cleared, access to the *IODATA* register via configuration address space is ignored and has no effect on the register and the CSRs referenced by the *IOADDR* register.

## 9.5.5 Vital Product Data Registers

This capability is not available for Dummy functions.

The I350 supports access to a VPD structure stored in the EEPROM using the following set of registers.

**Note:** The VPD structure is available through all port functions. As the interface is common to all functions, accessing the VPD structure of one function while an access to the EEPROM is in process on another function can yield unexpected results.

| Byte Offset | Byte 3      | Byte 2 | Byte 1              | Byte 0               |
|-------------|-------------|--------|---------------------|----------------------|
| 0xE0        | VPD address |        | Next Pointer (0x00) | Capability ID (0x03) |
| 0xE4        | VPD data    |        |                     |                      |

### 9.5.5.1 Capability ID (0xE0; RO)

This field equals 0x3 indicating the linked list item as being the VPD registers.

### 9.5.5.2 Next Pointer (0xE1; RO)

Offset to the next capability item in the capability list. A 0x00 value indicates that it is the last item in the capability-linked list.

### 9.5.5.3 VPD Address (0xE2; RW)

Dword-aligned byte address of the VPD area in the EEPROM to be accessed. The register is read/write with the initial value at power-up indeterminate.

| Bits | Default | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|------|---------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14:0 | X       | RW  | Address<br>Dword-aligned byte address of the VPD area in the EEPROM to be accessed. The register is read/write with the initial value at power-up indeterminate. The two LSBs are RO as zero. This is the address relative to the start of the VPD area. As the maximal size supported by the I350 is 256 bytes, bits 14:8 should always be zero.                                                    |
| 15   | 0b      | RW  | A flag used to indicate when the transfer of data between the VPD Data register and the storage component completes. The Flag register is written when the VPD Address register is written.<br>0b = Read. Set by hardware when data is valid.<br>1b = Write. Cleared by hardware when data is written to the EEPROM.<br>The VPD address and data should not be modified before the action completes. |

### 9.5.5.4 VPD Data (0xE4; RW)

This register contains the VPD read/write data.

| Bits | Default | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|---------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | X       | RW  | VPD Data<br>VPD data can be read or written through this register. The LSB of this register (at offset four in this capability structure) corresponds to the byte of VPD at the address specified by the VPD Address register. The data read from or written to this register uses the normal PCI byte transfer capabilities. Four bytes are always transferred between this register and the VPD storage component. Reading or writing data outside of the VPD space in the storage component is not allowed.<br>In a write access, the data should be set before the address and the flag is set. |

## 9.5.6 PCIe Configuration Registers

PCIe provides two mechanisms to support native features:

- PCIe defines a PCI capability pointer indicating support for PCIe.
- PCIe extends the configuration space beyond the 256 bytes available for PCI to 4096 bytes.

The I350 implements the PCIe capability structure for endpoint devices as follows:

### 9.5.6.1 Capability ID (0xA0; RO)

| Byte Offset | Byte 3                                   | Byte 2 | Byte 1                       | Byte 0               |
|-------------|------------------------------------------|--------|------------------------------|----------------------|
| 0xA0        | PCI Express Capability Register (0x0002) |        | Next Pointer (0xE0/<br>0x00) | Capability ID (0x10) |
| 0xA4        | Device Capability                        |        |                              |                      |
| 0xA8        | Device Status                            |        | Device Control               |                      |
| 0xAC        | Link Capabilities                        |        |                              |                      |
| 0xB0        | Link Status                              |        | Link Control                 |                      |
| 0xB4        | Reserved                                 |        |                              |                      |
| 0xB8        | Reserved                                 |        | Reserved                     |                      |
| 0xBC        | Reserved                                 |        |                              |                      |
| 0xC0        | Reserved                                 |        | Reserved                     |                      |
| 0xC4        | Device Capabilities 2                    |        |                              |                      |
| 0xC8        | Reserved                                 |        | Device Control 2             |                      |
| 0xCC        | Reserved                                 |        |                              |                      |
| 0xD0        | Link Status 2                            |        | Link Control 2               |                      |
| 0xD4        | Reserved                                 |        |                              |                      |
| 0xD8        | Reserved                                 |        | Reserved                     |                      |

This field equals 0x10 indicating the linked list item as being the PCIe Capabilities registers.

### 9.5.6.2 Next Pointer (0xA1; RO)

Offset to the next capability item in the capability list. Its value of 0xE0 points to the VPD structure. If VPD is disabled, operation is EEPROM-less or function is a dummy function, a value of 0x00 value indicates that it is the last item in the capability-linked list.

### 9.5.6.3 PCIe CAP (0xA2; RO)

The PCIe capabilities register identifies the PCIe device type and associated capabilities. This is a read only register identical to all functions.

| Bits  | Default | R/W | Description                                                                                                                                                                                       |
|-------|---------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0   | 0010b   | RO  | Capability Version<br>Indicates the PCIe capability structure version number. The I350 supports both version 1 and version 2 as loaded from the PCIe <i>Capability Version</i> bit in the EEPROM. |
| 7:4   | 0000b   | RO  | Device/Port Type<br>Indicates the type of PCIe functions. All functions are a native PCI function with a value of 0000b.                                                                          |
| 8     | 0b      | RO  | Slot Implemented<br>The I350 does not implement slot options therefore this field is hardwired to 0b.                                                                                             |
| 13:9  | 00000b  | RO  | Interrupt Message Number<br>The I350 does not implement multiple MSI interrupts per function, therefore this field is hardwired to 0x0.                                                           |
| 15:14 | 00b     | RO  | Reserved                                                                                                                                                                                          |

### 9.5.6.4 Device Capabilities (0xA4; RO)

This register identifies the PCIe device specific capabilities. It is a read only register with the same value for all functions.

| Bits  | R/W | Default         | Description                                                                                                                                                                                                                                                                                                       |
|-------|-----|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2:0   | RO  | 010b            | Max Payload Size Supported<br>This field indicates the maximum payload that the I350 can support for TLPs. It is loaded from the EEPROM's <i>PCIe Init Configuration 3</i> word, 0x1A (with a default value of 512 bytes).                                                                                        |
| 4:3   | RO  | 00b             | Phantom Function Supported<br>Not supported by the I350.                                                                                                                                                                                                                                                          |
| 5     | RO  | 0b              | Extended Tag Field Supported<br>Max supported size of the <i>Tag</i> field. The I350 supported 5-bit <i>Tag</i> field for all functions.                                                                                                                                                                          |
| 8:6   | RO  | 011b            | Endpoint L0s Acceptable Latency<br>This field indicates the acceptable latency that the I350 can withstand due to the transition from the L0s state to the L0 state. All functions share the same value loaded from the EEPROM <i>PCIe Init Configuration 1</i> word, 0x18 (See <a href="#">Section 6.2.14</a> ). |
| 11:9  | RO  | 110b            | Endpoint L1 Acceptable Latency<br>This field indicates the acceptable latency that the I350 can withstand due to the transition from the L1 state to the L0 state. All functions share the same value loaded from the EEPROM <i>PCIe L1 Exit latencies</i> word, 0x14 (See <a href="#">Section 6.2.11</a> ).      |
| 12    | RO  | 0b              | Attention Button Present<br>Hardwired in the I350 to 0b for all functions.                                                                                                                                                                                                                                        |
| 13    | RO  | 0b              | Attention Indicator Present<br>Hardwired in the I350 to 0b for all functions.                                                                                                                                                                                                                                     |

### 9.5.6.6 Device Status (0xAA; R/W1C)

This register provides information about PCIe device's specific parameters. There is a dedicated register per each function.

| Bits | R/W   | Default | Description                                                                                                                                                                                      |
|------|-------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | R/W1C | 0b      | Correctable Error Detected<br>Indicates status of correctable error detection.                                                                                                                   |
| 1    | R/W1C | 0b      | Non-Fatal Error Detected<br>Indicates status of non-fatal error detection.                                                                                                                       |
| 2    | R/W1C | 0b      | Fatal Error Detected<br>Indicates status of fatal error detection.                                                                                                                               |
| 3    | R/W1C | 0b      | Unsupported Request Detected<br>Indicates that the I350 received an unsupported request. This field is identical in all functions. The I350 cannot distinguish which function caused an error.   |
| 4    | RO    | 0b      | Aux Power Detected<br>If aux power is detected, this field is set to 1b. It is a strapping signal from the periphery identical for all functions. Reset on LAN_PWR_GOOD and GIO Power Good only. |
| 5    | RO    | 0b      | Transactions Pending<br>Indicates whether the I350 has any transaction pending.                                                                                                                  |
| 15:6 | RO    | 0x00    | Reserved                                                                                                                                                                                         |

### 9.5.6.7 Link Capabilities Register (0xAC; RO)

This register identifies PCIe link specific capabilities. This is a read only register identical to all functions.

| Bits  | Rd/Wr | Default | Description                                                                                                                                                                                                                                                                                                                                                |
|-------|-------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0   | RO    | 0010b   | Max Link Speed<br>This field indicates the supported Link speed(s) of the associated link port. Defined encodings are:<br>0001b = 2.5 Gb/s Link speed supported.<br>0010b = 5 Gb/s and 2.5 Gb/s Link speeds supported.<br>Value of this field is determined by the <i>Disable PCIe Gen 2</i> bit in the <i>PCIe PHY Auto Configuration</i> EEPROM section. |
| 9:4   | RO    | 0x4     | Max Link Width<br>Indicates the maximum link width. The I350 can support by 1-, by 2- and by 4-link width. The field is loaded from the EEPROM (See <a href="#">Section 6.3.5.5.2</a> ), with a default value of four lanes.<br><br>Relevant encoding:<br>000000b = Reserved.<br>000001b = x1.<br>000010b = x2.<br>000100b = x4.                           |
| 11:10 | RO    | 11b     | Active State Power Management (ASPM) Support – This field indicates the level of ASPM supported on the I350 PCI Express Link.<br>Defined encodings are:<br>00b = No ASPM Support.<br>01b = L0s Supported.<br>10b = L1 Supported.<br>11b = L0s and L1 Supported.                                                                                            |

| Bits  | Rd/Wr  | Default                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 9.5.6.8 Link Control Register (0xB0; RO)

This register controls PCIe link specific parameters. There is a dedicated register per each function.

| Bits  | R/W | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 1:0   | RW  | 00b     | Active State Power Management (ASPM) Control – This field controls the level of Active State Power Management (ASPM) supported on the I350 PCI Express Link. For non-ARI mode, only capabilities enabled in all Functions are enabled for the component as a whole. When ARI support is exposed, ASPM Control is determined solely by the setting in Function 0 (even when it is a dummy function), regardless of Function 0's D-state. The settings in the other Functions always return whatever value software programmed for each, but otherwise are ignored by the I350.<br>Defined encodings are:<br>00b = PM disabled.<br>01b = L0s entry supported.<br>10b = L1 Entry Enabled.<br>11b = L0s and L1 supported.<br>Note: "L0s Entry Enabled" enables the Transmitter to enter L0s is supported. If L0s is supported, the Receiver must be capable of entering L0s even when the Transmitter is disabled from entering L0s (00b or 10b). |

| 6     | RW  | 0b      | Common Clock Configuration<br>When this bit is set, it indicates that the I350 and the component at the other end of the link are operating with a common reference clock. A value of 0b indicates that both operate with an asynchronous clock. This parameter affects the L0s exit latencies.<br>When ARI support is exposed, the value set in function zero (even when it is a dummy function), is the value used for all the functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 7     | RW  | 0b      | Extended Synch<br>When this bit is set, it forces an extended Tx of a FTS ordered set in FTS and an extra TS1 at exit from L0s prior to enter L0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 9.5.6.9 Link Status (0xB2; RO)

This register provides information about PCIe link specific parameters. This is a read only register identical to all functions.

| Bits | R/W    | Default | Description                                                                                                                                                                                                                                                                                                                                                  |

### 9.5.6.10 Reserved (0xB4-0xC0; RO)

Unimplemented reserved registers not relevant to PCIe endpoint.

The following registers are supported only if the capability version is two and above.

### 9.5.6.11 Device Capabilities 2 (0xC4; RO)

This register identifies PCIe device specific capabilities. It is a read only register with the same value for all functions.

| Bit Location | R/W | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

1. Value loaded from EEPROM word.

### 9.5.6.12 Device Control 2 (0xC8; RW)

This register controls PCIe specific parameters. There is a dedicated register per each function.

| Bit location | R/W | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

For requests already pending when the completion timeout value is changed, hardware is permitted to use either the new or the old value for the outstanding requests and is permitted to base the start time for each request either when this value was changed or when each request was issued.</p> <p>The default value for this field is 0000b.</p> <p>For Dummy function, this field is RO - zero.</p> |
| 4            | RW  | 0b      | <p>Completion Timeout Disable</p> <p>When set to 1b, this bit disables the completion timeout mechanism.</p> <p>Software is permitted to set or clear this bit at any time. When set, the completion timeout detection mechanism is disabled. If there are outstanding requests when the bit is cleared, it is permitted but not required for hardware to apply the completion timeout mechanism to the outstanding requests. If this is done, it is permitted to base the start time for each request on either the time this bit was cleared or the time each request was issued.</p> <p>The default value for this bit is 0b.</p> <p>For Dummy function, this field is RO - zero.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

1. The completion timeout value must be programmed correctly in PCIe configuration space (in Device Control 2 Register); the value must be set above the expected maximum latency for completions in the system in which the I350 is installed. This will ensure that the I350 receives the completions for the requests it sends out, avoiding a completion timeout scenario. It is expected that the system BIOS will set this value appropriately for the system.
2. RW for Function 0, RO with a value of 0 for all other functions

### 9.5.6.13 Link Control 2 (0xD0; RW)

| 15:1 | RO  | 0x0     | Reserved                                                                                                                                                                                                                                    |

## 9.6 PCIe Extended Configuration Space

PCIe extended configuration space is located in a flat memory-mapped address space. PCIe extends the configuration space beyond the 256 bytes available for PCI to 4096 bytes. The I350 decodes an additional 4-bits (bits 27:24) to provide the additional configuration space as shown in [Table 9-15](#). PCIe reserves the remaining 4 bits (bits 31:28) for future expansion of the configuration space beyond 4096 bytes.

The configuration address for a PCIe device is computed using a PCI-compatible bus, device, and function numbers as follows.

**Table 9-15 PCIe Extended Configuration Space**

| 31    | 28 | 27    | 20 | 19       | 15 | 14    | 12 | 11                        | 2 | 1   | 0 |
|-------|----|-------|----|----------|----|-------|----|---------------------------|---|-----|---|
| 0000b |    | Bus # |    | Device # |    | Fun # |    | Register Address (offset) |   | 00b |   |

PCIe extended configuration space is allocated using a linked list of optional or required PCIe extended capabilities following a format resembling PCI capability structures. The first PCIe extended capability is located at offset 0x100 in the device configuration space. The first Dword of the capability structure identifies the capability/version and points to the next capability.

The I350 supports the following PCIe extended capabilities.

**Table 9-16 PCIe Extended Capability Structure**

| Capability                              | Offset | Next Header                                      |
|-----------------------------------------|--------|--------------------------------------------------|
| Advanced Error Reporting                | 0x100  | 0x140/0x150/0x160/0x1A0/0x1C0/0x1D0 <sup>1</sup> |
| Serial Number <sup>2</sup>              | 0x140  | 0x150/0x160/0x1A0/0x1C0/0x1D0 <sup>3</sup>       |
| Alternative RID Interpretation (ARI)    | 0x150  | 0x160/0x1A0/0x1C0/0x1D0                          |
| IOV support                             | 0x160  | 0x1A0 <sup>4</sup>                               |
| TLP processing hints                    | 0x1A0  | 0x1C0/0x1D0 <sup>5 4</sup>                       |
| Latency Tolerance Requirement Reporting | 0x1C0  | 0x1D0                                            |
| Access Control Services                 | 0x1D0  | 0x000                                            |

1. Depends on EEPROM settings enabling the Serial Number, ARI structure, IOV structure and LTR in EEPROM. A dummy function will point from the AER structure to the Serial Number structure. If Serial Number structure is disabled, then AER points to the ARI Structure. If ARI is also disabled a dummy function will point from the AER structure to the LTR structure, otherwise if the LTR structure is also disabled the AER structure points to the ACS structure.
2. Not available in EEPROM-less systems.
3. A dummy function will point from the Serial Number structure to the ARI Structure. If ARI is also disabled a dummy function will point from the Serial Number structure to the LTR structure, otherwise if the LTR structure is also disabled the Serial Number structure points to the ACS structure.
4. In a dummy function, the IOV and TPH structures are not exposed.
5. If LTR is enabled the TPH structure points to the LTR structure, otherwise it points to the ACS structure.

## 9.6.1 Advanced Error Reporting (AER) Capability

The PCIe AER capability is an optional extended capability to support advanced error reporting. The following table lists the PCIe AER extended capability structure for PCIe devices.

| Byte Offset    | Byte 3                                                                          | Byte 2        | Byte 1                     | Byte 0 |
|----------------|---------------------------------------------------------------------------------|---------------|----------------------------|--------|
| 0x100          | Next Capability Ptr.<br>(0x140/0x150/0x160/<br>0x1A0/0x1C0/0x1D0 <sup>1</sup> ) | Version (0x2) | AER Capability ID (0x0001) |        |
| 0x104          | Uncorrectable Error Status                                                      |               |                            |        |
| 0x108          | Uncorrectable Error Mask                                                        |               |                            |        |
| 0x10C          | Uncorrectable Error Severity                                                    |               |                            |        |
| 0x110          | Correctable Error Status                                                        |               |                            |        |
| 0x114          | Correctable Error Mask                                                          |               |                            |        |
| 0x118          | Advanced Error Capabilities and Control Register                                |               |                            |        |
| 0x11C... 0x128 | Header Log                                                                      |               |                            |        |

1. Depends on EEPROM settings, enabling the Serial Number, enabling ARI structure, IOV structure and enabling LTR. A dummy function will point from the AER structure to the ARI structure. If ARI is disabled, it will point to the LTR structure, if LTR is disabled then it will point to the ACS structure.

### 9.6.1.1 PCIe CAP ID (0x100; RO)

| Bit Location | Attribute | Default Value                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 31:20        | RO        | 0x1D0/<br>0x1C0/<br>0x1A0/<br>0x160/<br>0x150/<br>0x140 | Next Capability Pointer<br>Next PCIe extended capability pointer. A value of 0x140 points to the serial ID capability. In EEPROM-less systems or when serial ID is disabled in the EEPROM, the next pointer is 0x150 and points to the ARI capability structure. If ARI is also disabled in the EEPROM the next pointer is 0x160 and points to the IOV capability structure. If IOV is also disabled in the EEPROM this field points to the TPH capability structure (0x1A0).<br>Note: If function is a dummy function, depending on the capability structures disabled in the EEPROM, this field can point to either 0x140 (Serial ID), 0x150 (ARI), 0x1C0 (LTR) or 0x1D0 (ACS). |

1. Loaded from EEPROM (See [Section 6.2.19](#)).

### 9.6.1.2 Uncorrectable Error Status (0x104; R/W1CS)

The Uncorrectable Error Status register reports error status of individual uncorrectable error sources on a PCIe device. An individual error status bit that is set to 1b indicates that a particular error occurred; software can clear an error status by writing a 1b to the respective bit.

| Bit Location | Attribute | Default Value | Description                                                                  |

### 9.6.1.3 Uncorrectable Error Mask (0x108; RWS)

The Uncorrectable Error Mask register controls reporting of individual uncorrectable errors by device to the host bridge via a PCIe error message. A masked error (respective bit set in mask register) is not reported to the host bridge by an individual device. There is a mask bit per bit in the Uncorrectable Error Status register.

| Bit Location | Attribute | Default Value | Description                                                       |
|--------------|-----------|---------------|-------------------------------------------------------------------|
| 3:0          | RO        | 0x0           | Reserved                                                          |
| 4            | RWS       | 0b            | Data Link Protocol Error Mask                                     |

| 31:26        | RO        | 0x0           | Reserved                                                                   |

### 9.6.1.4 Uncorrectable Error Severity (0x10C; RWS)

The Uncorrectable Error Severity register controls whether an individual uncorrectable error is reported as a fatal error. An uncorrectable error is reported as fatal when the corresponding error bit in the severity register is set. If the bit is cleared, the corresponding error is considered non-fatal.

| Bit Location | Attribute | Default Value | Description                                                                    |
|--------------|-----------|---------------|--------------------------------------------------------------------------------|
| 3:0          | RO        | 0001b         | Reserved                                                                       |
| 4            | RWS       | 1b            | Data Link Protocol Error Severity                                              |
| 5            | RO        | 1b            | Surprise Down Error Severity (Optional)<br>Not supported in the I350.          |

| 25           | RO        | 0b            | TLP Prefix Blocked Error Severity (Optional)<br>Not supported in the I350. |
| 31:26        | RO        | 0x0           | Reserved                                                                   |

### 9.6.1.5 Correctable Error Status (0x110; R/W1CS)

The Correctable Error Status register reports error status of individual correctable error sources on a PCIe device. When an individual error status bit is set to 1b, it indicates that a particular error occurred; software can clear an error status by writing a 1b to the respective bit.

| Bit Location | Attribute | Default Value | Description                                                              |
|--------------|-----------|---------------|--------------------------------------------------------------------------|
| 0            | R/W1CS    | 0b            | Receiver Error Status                                                    |
| 5:1          | RO        | 0x0           | Reserved                                                                 |
| 6            | R/W1CS    | 0b            | Bad TLP Status                                                           |
| 7            | R/W1CS    | 0b            | Bad DLLP Status                                                          |

| 11:9         | RO        | 000           | Reserved                                                                 |
| 12           | R/W1CS    | 0b            | Replay Timer Timeout Status                                              |
| 13           | R/W1CS    | 0b            | Advisory Non-Fatal Error Status                                          |
| 14           | RO        | 0b            | Corrected Internal Error Status (Optional)<br>Not supported in the I350. |
| 15           | RO        | 0b            | Header Log Overflow Status (Optional)<br>Not supported in the I350.      |
| 31:16        | RO        | 0x0           | Reserved                                                                 |

### 9.6.1.6 Correctable Error Mask (0x114; RWS)

The Correctable Error Mask register controls reporting of individual correctable errors by device to the host bridge via a PCIe error message. A masked error (respective bit set in mask register) is not reported to the host bridge by an individual device. There is a mask bit per bit in the Correctable Error Status register.

| Bit Location | Attribute | Default Value | Description               |
|--------------|-----------|---------------|---------------------------|
| 0            | RWS       | 0b            | Receiver Error Mask       |
| 5:1          | RO        | 0x0           | Reserved                  |
| 6            | RWS       | 0b            | Bad TLP Mask              |
| 7            | RWS       | 0b            | Bad DLLP Mask             |
| 8            | RWS       | 0b            | REPLAY_NUM Rollover Mask  |
| 11:9         | RO        | 000b          | Reserved                  |

### 9.6.1.8 Header Log (0x11C:0x128; RO)

The Header Log register captures the header for the transaction that generated an error. This register is 16 bytes in length.

| Bit Location | Attribute | Default Value | Description                                  |
|--------------|-----------|---------------|----------------------------------------------|
| 127:0        | ROS       | 0b            | Header of the packet in error (TLP or DLLP). |

## 9.6.2 Serial Number

The PCIe device serial number capability is an optional extended capability that can be implemented by any PCIe device. The device serial number is a read-only 64-bit value that is unique for a given PCIe device.

All multi-function devices that implement this capability must implement it for function 0; other functions that implement this capability must return the same device serial number value as that reported by function 0.

**Note:** The I350 does not support this capability in an EEPROM-less configuration.

| Byte Offset | Byte 3                                                                     | Byte 2        | Byte 1                           | Byte 0 |
|-------------|----------------------------------------------------------------------------|---------------|----------------------------------|--------|
| 0x140       | Next Capability Ptr.<br>(0x150/0x160/0x1A0/<br>0x1C0/0x1D0) <sup>1 2</sup> | Version (0x1) | Serial ID Capability ID (0x0003) |        |
| 0x144       | Serial Number Register (Lower Dword)                                       |               |                                  |        |
| 0x148       | Serial Number Register (Upper Dword)                                       |               |                                  |        |

1. If ARI structure is enabled in EEPROM value of field is 0x150 that points to ARI capability structure, otherwise if IOV structure is enabled in EEPROM value of field is 0x160 otherwise value of field is 0x1A0 that points to the TPH capability structure.
2. If function is a dummy function, if ARI structure is enabled in EEPROM value of field is 0x150 that points to ARI capability structure, otherwise if LTR is enabled in the EEPROM value of field is 0x1C0 that points to LTR capability structure otherwise value of the field is 0x1D0 that points to the ACS capability structure.

### 9.6.2.1 Device Serial Number Enhanced Capability Header (0x140; RO)

The following table lists the allocation of register fields in the device serial number enhanced capability header. It also lists the respective bit definitions. The extended capability ID for the device serial number capability is 0x0003.

| Bit(s) Location | Default value                                 | Attributes | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## 9.6.2.2 Serial Number Register (0x144:0x148; RO)

The Serial Number register is a 64-bit field that contains the IEEE defined 64-bit extended unique identifier (EUI-64™). [Table 9-17](#) lists the allocation of register fields in the Serial Number register. [Table 9-17](#) also lists the respective bit definitions.

**Table 9-17 Serial Number Register**

|                                      |
|--------------------------------------|
| <b>31:0</b>                          |
| Serial Number Register (Lower Dword) |
| Serial Number Register (Upper word)  |
| <b>63:32</b>                         |

Serial number definition in the I350:

**Table 9-18 SN Definition**

| Bit(s)<br>Location | Attributes | Description                                                                                                                                                                                                                                                               |
|--------------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0               | RO         | PCIe Device Serial Number<br>This field contains the IEEE defined 64-bit extended unique identifier (EUI-64™). This identifier includes a 24-bit company ID value assigned by IEEE registration authority and a 40-bit extension identifier assigned by the manufacturer. |

Serial number uses the MAC address according to the following definition:

| Field | Extension identifier  |        |        |        |        | Company ID             |        |        |
|-------|-----------------------|--------|--------|--------|--------|------------------------|--------|--------|
| Order | Addr+0                | Addr+1 | Addr+2 | Addr+3 | Addr+4 | Addr+5                 | Addr+6 | Addr+7 |
|       | Most significant byte |        |        |        |        | Least significant byte |        |        |
|       | Most significant bit  |        |        |        |        | Least significant bit  |        |        |

The serial number can be constructed from the 48-bit MAC address in the following form:

| Field | Extension identifier   |        |        | MAC Label |        | Company ID             |        |        |
|-------|------------------------|--------|--------|-----------|--------|------------------------|--------|--------|
| Order | Addr+0                 | Addr+1 | Addr+2 | Addr+3    | Addr+4 | Addr+5                 | Addr+6 | Addr+7 |
|       | Most significant bytes |        |        |           |        | Least significant byte |        |        |
|       | Most significant bit   |        |        |           |        | Least significant bit  |        |        |

The MAC label in this case is 0xFFFF.

For example, assume that the company ID is (Intel) 00-A0-C9 and the extension identifier is 23-45-67. In this case, the 64-bit serial number is:

| Field | Extension identifier  |        |        | MAC Label |        | Company ID             |        |        |
|-------|-----------------------|--------|--------|-----------|--------|------------------------|--------|--------|
| Order | Addr+0                | Addr+1 | Addr+2 | Addr+3    | Addr+4 | Addr+5                 | Addr+6 | Addr+7 |
|       | 67                    | 45     | 23     | FF        | FF     | C9                     | A0     | 00     |
|       | Most significant byte |        |        |           |        | Least significant byte |        |        |
|       | Most significant bit  |        |        |           |        | Least significant bit  |        |        |

The MAC address is the function 0 MAC address as loaded from the EEPROM into the RAL and RAH registers.

The translation from EEPROM words 0 to 2 to the serial number is as follows:

- Serial number ADDR+0 = EEPROM byte 5
- Serial number ADDR+1 = EEPROM byte 4
- Serial number ADDR+2 = EEPROM byte 3
- Serial number ADDR+3,4 = 0xFF 0xFF
- Serial number ADDR+5 = EEPROM byte 2
- Serial number ADDR+6 = EEPROM byte 1
- Serial number ADDR +7 = EEPROM byte 0

The official document defining EUI-64 is: <http://standards.ieee.org/regauth/oui/tutorials/EUI64.html>

### 9.6.3 ARI Capability Structure

In order to enable more than eight functions per end point without requesting an internal switch (typically needed in virtualization scenarios), the PCI-SIG defines a new capability that enables a different interpretation of the *Bus*, *Device*, and *Function* fields. The Alternate Requester ID Interpretation (ARI) capability structure is as follows:

| Byte Offset | Byte 3                                                               | Byte 2        | Byte 1                     | Byte 0 |
|-------------|----------------------------------------------------------------------|---------------|----------------------------|--------|
| 0x150       | Next Capability Ptr.<br>(0x160/0x1A0/0x1C0/<br>0x1D0) <sup>1 2</sup> | Version (0x1) | ARI Capability ID (0x000E) |        |
| 0x154       | ARI Capabilities & Control Register                                  |               |                            |        |

1. If function is not a Dummy function next capability structure is 0x160 that points to the IOV structure and if IOV is disabled in the EEPROM value of field is 0x1A0 that points to the TPH capability structure.
2. If function is a Dummy function and LTR is enabled in the EEPROM, value in field is 0x1C0 that points to the LTR capability structure, otherwise if LTR is disabled, value of field is 0x1D0 that points to the ACS capability structure.

#### 9.6.3.1 PCIe ARI Header Register (0x150; RO)

| Bit(s) | Initial Value                       | Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 31:23  | 0x0                                                                       | RO     | Reserved                                                                                                                                                                                                                                                                                                      |

1. If port 0, port 1, port 2 or port 3 are switched or function zero is a dummy function, this register should keep its attributes according to the function number. If part of the LANs are disabled, then the value of this field should create a valid link list between all the functions that are enabled. In the last function this field should be zero.

### 9.6.4 SR-IOV Capability Structure

This is the structure used to support the IOV capabilities reporting and control.

**Note:** This capability structure is not exposed in a Dummy function.

| Byte Offset | Byte 3                         | Byte 2                        | Byte 1                     | Byte 0 |
|-------------|--------------------------------|-------------------------------|----------------------------|--------|

| 15:0   | 0x8           | RO     | <p><b>InitialVFs</b></p> <p><b>InitialVFs</b> indicates the number of VFs that are initially associated with the PF. If VF migration capable is clear, this field must contain the same value as TotalVFs.</p> <p>A lower value of this field can be loaded from the IOV control word in the EEPROM.</p> |

Table 9-19 PCIe SR-IOV Max/Total VFs Register (0x16C) (Continued)

| Bit(s) | Initial Value | Access | Description                                                                                                                                            |
|--------|---------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16  | 0x8           | RO     | <b>TotalVFs</b><br><b>TotalVFs</b> indicates the maximum number of VFs that could be associated with the PF. In the I350, this is equal to InitialVFs. |

### 9.6.4.5 PCIe SR-IOV Num VFs Register (0x170; R/W)

| Bit(s) | Initial Value                                                             | Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|---------------------------------------------------------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0   | 0x0                                                                       | R/W    | <b>NumVFs</b><br><b>NumVFs</b> define the number of VFs software has assigned to the PF. Software sets NumVFs as part of the process of creating VFs. NumVFs VFs must be visible in the PCIe fabric after both NumVFs are set to a valid value and <i>VF Enable</i> is set to 1b. Visible in the PCIe fabric means that the VF must respond to PCIe transactions targeting the VF, following all other rules defined by this specification and the base specification.<br>The results are undefined if NumVFs are set to a value greater than TotalVFs. NumVFs can only be written while <i>VF Enable</i> is clear. The NumVFs field is RO when <i>VF Enable</i> is set. |
| 23:16  | 0x0 (func 0)<br>0x1 (func 1)<br>0x2 (func 2)<br>0x3 (func 3) <sup>1</sup> | RO     | <b>FDL - Function Dependency Link</b><br>Defines dependencies between physical functions allocation. The default behavior of the I350 is not to define any such constraints.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 31:24  | 0x0                                                                       | RO     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

1. If port 0, port 1, port 2 or port 3 are switched or function zero is a dummy function, this register should keep its attributes according to the function number.

### 9.6.4.6 PCIe SR-IOV VF RID Mapping Register (0x174; RO)

See Section 7.8.2.6 for details of the RID mapping.

| Bit(s) | Initial Value | Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|---------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0   | 0x180         | RO     | <b>FVO</b><br><b>First VF offset</b> defines the requestor ID (RID) offset of the first VF that is associated with the PF that contains this capability structure. The first VFs 16-bit RID is calculated by adding the contents of this field to the RID of the PF containing this field.<br>The content of this field is valid only when <i>VF Enable</i> is set. If <i>VF Enable</i> is 0b, the contents are undefined.<br>If the <i>ARI Enable</i> bit is set, this field changes to 0x80. |
| 31:16  | 0x4           | RO     | <b>VFS</b><br><b>VF Stride</b> defines the Requestor ID (RID) offset from one VF to the next one for all VFs associated with the PF that contains this capability structure. The next VFs 16-bit RID is calculated by adding the contents of this field to the RID of the current VF.<br>The content of this field is valid only when <i>VF Enable</i> is set and NumVFs are a non-zero. If <i>VF Enable</i> is 0b or if NumVFs are zero, the contents are undefined.                          |

### 9.6.4.7 PCIe SR-IOV VF device ID (0x178; RO)

| Bit(s) | Initial Value | Access | Description                                                                                                                                                       |
|--------|---------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16  | 0x1520        | RO     | This field contain the Device ID that should be presented for every VF to the Virtual Machine software. The value of this field may be read from EEPROM word 0x26 |
| 15:0   | 0x0           | RO     | Reserved                                                                                                                                                          |

### 9.6.4.8 PCIe SR-IOV Supported Page Size Register (0x17C; RO)

| Bit(s) | Initial Value | Access | Description                                                                                                                                                                                                                                                                                                                  |
|--------|---------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0   | 0x553         | RO     | Supported page Size<br>For PFs that support the stride-based BAR mechanism, this field defines the supported page sizes. This PF supports a page size of $2^{(n+12)}$ if bit n is set. For example, if bit 0 is set, the EP supports 4 KB page sizes. The I350 supports 4 KB, 8 KB, 64 KB, 256 KB, 1 MB and 4 MB page sizes. |

### 9.6.4.9 PCIe SR-IOV System Page Size Register (0x180; R/W)

| Bit(s) | Initial Value | Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|---------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0   | 0x1           | R/W    | Page Size<br>This field defines the page size the system uses to map the PF's and associated VFs' memory addresses. Software must set the value of the system page size to one of the page sizes set in the <i>Supported Page Sizes</i> field. As with supported page sizes, if bit n is set in system page size, the PF and its associated VFs are required to support a page size of $2^{(n+12)}$ . For example, if bit 1 is set, the system is using an 8 KB page size. The results are undefined if more than one bit is set in system page size. The results are undefined if a bit is set in a system page size that is not set in supported page sizes.<br>When system page size is set, the PF and associated VFs are required to align all BAR resources on a system page size boundary. Each BAR size, including VF BARn size (described in the sections that follow) must be aligned on a system page size boundary. Each BAR size, including VF BARn size must be sized to consume a multiple of system page size bytes. All fields requiring page size alignment within a function must be aligned on a system page size boundary. <i>VF Enable</i> must be set to 0b when system page size is set. The results are undefined if system page size is set when <i>VF Enable</i> is set. |

### 9.6.4.10 PCIe SR-IOV BAR 0 - Low Register (0x184; R/W)

|--------|---------------|--------|-------------------------------|
| 31:0   | 0x0           | RO     | BAR5<br>This BAR is not used. |

#### 9.6.4.16 PCIe SR-IOV VF Migration State Array Offset (0x19C;

RO)

| Bit(s) | Initial Value | Access | Description                                                                                                    |
|--------|---------------|--------|----------------------------------------------------------------------------------------------------------------|
| 2:0    | 000b          | RO     | BIR: Indicates which PF BAR contains the VF migration state array. Not implemented in the I350.                |
| 31:0   | 0x0           | RO     | Offset, relative to the beginning of the BAR of the start of the migration array. Not implemented in the I350. |

## 9.6.5 TLP Processing Hint Requester (TPH) Capability

The PCIe TPH Requester capability is an optional extended capability to support TLP Processing Hints. The following table lists the PCIe TPH extended capability structure for PCIe devices.

**Note:** This capability structure is not exposed in a Dummy function.

| Byte Offset | Byte 3                                              | Byte 2        | Byte 1                   | Byte 0 |
|-------------|-----------------------------------------------------|---------------|--------------------------|--------|
| 0x1A0       | Next Capability Ptr.<br>(0x1C0/0x1D0 <sup>1</sup> ) | Version (0x1) | TPH Capability ID (0x17) |        |
| 0x1A4       | TPH Requester Capability Register                   |               |                          |        |
| 0x1A8       | TPH Requester Control Register                      |               |                          |        |
| 0x1AC-0x1B8 | TPH ST Table                                        |               |                          |        |

1. Depends on EEPROM settings of the *LTR\_EN* bit in *Initialization Control Word 1* EEPROM word, that controls enabling of the LTR structures.

### 9.6.5.1 TPH CAP ID (0x1A0; RO)

| Bit Location | Attribute | Default Value                | Description                                                                                                                                                                                                                                                                                                    |

| 7:0          | RW        | 0x0           | Steering Table Lower Entry $2*n$ ( $n = 0...3$ ). A value of zero indicates the tag is not valid                |
| 15:8         | RO        | 0x0           | Steering Table Upper Entry $2*n$ ( $n = 0...3$ ) - RO zero in the I350, as extended tags are not supported.     |
| 23:16        | RW        | 0x0           | Steering Table Entry $2*n + 1$ ( $n = 0...3$ ) - A value of zero indicates the tag is not valid                 |
| 31:24        | RO        | 0x0           | Steering Table Upper Entry $2*n + 1$ ( $n = 0...3$ ) - RO zero in the I350, as extended tags are not supported. |

### 9.6.6 Latency Tolerance Requirement Reporting (LTR) Capability

The PCI Express Latency Tolerance Requirement Reporting Capability is an optional Extended Capability that allows software to provide platform latency information to devices with upstream ports (Endpoints and Switches). This capability structure is required if the device supports Latency Tolerance Requirement Reporting (LTR).

**Note:** The LTR Capability structure is implemented only in Function 0 even when Function 0 is a dummy function, and controls the component's Link behavior on behalf of all the Functions of the device

The following table lists the PCIe LTR extended capability structure for PCIe devices.

| Byte Offset | Byte 3                                                  | Byte 2        | Byte 1                                              | Byte 0 |
|-------------|---------------------------------------------------------|---------------|-----------------------------------------------------|--------|
| 0x1C0       | Next Capability Ptr. (0x1D0)                            | Version (0x1) | LTR Capability ID (0x18)                            |        |
| 0x1C4       | Maximum Non-Snooped Platform Latency Tolerance Register |               | Maximum Snooped Platform Latency Tolerance Register |        |

#### 9.6.6.1 LTR CAP ID (0x1C0; RO)

| Bit Location | Attribute | Default Value | Description                                                                 |
|--------------|-----------|---------------|-----------------------------------------------------------------------------|
| 15:0         | RO        | 0x18          | LTR Capability ID<br>PCIe extended capability ID indicating LTR capability. |
| 19:16        | RO        | 0x1           | Version Number<br>PCIe LTR extended capability version number.              |
| 31:20        | RO        | 0x1D0         | Next Capability Pointer<br>Points to the ACS capability                     |

## 9.6.6.2 LTR Capabilities (0x1C4; RW)

| Bit Location | Attribute | Default Value | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|-----------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9:0          | RW        | 0x0           | Maximum Snoop Latency Value<br>Along with the Max Snoop Latency Scale field, this register specifies the maximum nosnoop latency that a device is permitted to request. Software should set this to the platform's maximum supported latency or less.<br>Field is also an indicator of the platforms maximum latency, should an endpoint send up LTR Latency Values with the Requirement bit not set.    |
| 12:10        | RW        | 0x0           | Max Snoop Latency Scale<br>This field provides a scale for the value contained within the Maximum Snoop Latency Value field.<br>Encoding:<br>000 – Value times 1ns<br>001 – Value times 32ns<br>010 – Value times 1,024ns<br>011 – Value times 32,768ns<br>100 – Value times 1,048,576ns<br>101 – Value times 33,554,432ns<br>110-111 – Not Permitted                                                    |
| 15:13        | RO        | 0x0           | Reserved                                                                                                                                                                                                                                                                                                                                                                                                 |
| 25:16        | RW        | 0x0           | Max No-Snoop Latency Value<br>Along with the Max No-Snoop Latency Scale field, this register specifies the maximum no-snoop latency that a device is permitted to request. Software should set this to the platform's maximum supported latency or less.<br>Field is also an indicator of the platforms maximum latency, should an endpoint send up LTR Latency Values with the Requirement bit not set. |
| 28:26        | RW        | 0x0           | Max No-Snoop Latency Scale — This register provides a scale for the value contained within the Maximum Non-Snoop Latency Value field.<br>Encoding:<br>000 – Value times 1 ns<br>001 – Value times 32 ns<br>010 – Value times 1,024 ns<br>011 – Value times 32,768 ns<br>100 – Value times 1,048,576 ns<br>101 – Value times 33,554,432 ns<br>110-111 – Not Permitted                                     |

## 9.6.7 Access Control Services (ACS) Capability

The PCI Express ACS defines a set of control points within a PCI Express topology to determine whether a TLP should be routed normally, blocked, or redirected. ACS is applicable to RCs, Switches, and multifunction devices

The following table lists the PCIe ACS extended capability structure for PCIe devices.

| Byte Offset | Byte 3                       | Byte 2        | Byte 1                        | Byte 0 |
|-------------|------------------------------|---------------|-------------------------------|--------|
| 0x1D0       | Next Capability Ptr. (0x000) | Version (0x1) | ACS Capability ID (0x0D)      |        |
| 0x1D4       | ACS Control Register (0x0)   |               | ACS Capability Register (0x0) |        |

### 9.6.7.1 ACS CAP ID (0x1D0; RO)

| Bit Location | Attribute | Default Value | Description                                                                           |
|--------------|-----------|---------------|---------------------------------------------------------------------------------------|
| 15:0         | RO        | 0x0D          | ACS Capability ID<br>PCIe extended capability ID indicating ACS capability.           |
| 19:16        | RO        | 0x1           | Version Number<br>PCIe ACS extended capability version number.                        |

| 1      | 0b            | RO  | MAE - Memory Access Enable<br>RO as a zero field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2      | 0b            | RW  | BME - Bus Master Enable<br>Disabling this bit prevents the associated VF from issuing any memory or I/O requests. Note that as MSI/MSI-X interrupt messages are in-band memory writes, disabling the bus master enable bit disables MSI/MSI-X interrupt messages as well.<br>Requests other than memory or I/O requests are not controlled by this bit.<br><b>Note:</b> The state of active transactions is not specified when this bit is disabled after being enabled. The I350 can choose how it behaves when this condition occurs. Software cannot count on the I350 retaining state and resuming without loss of data when the bit is re-enabled.<br>Transactions for a VF that has its <i>Bus Master Enable</i> bit set must not be blocked by transactions for VFs that have their <i>Bus Master Enable</i> bit cleared. |

| 31:3 | 0x400   | RO   | PBA Offset<br>Used as an offset from the address contained by one of the function's BARs to point to the base of the MSI-X PBA. The lower three PBA BIR bits are masked off (set to zero) by software to form a 32-bit Qword-aligned offset.<br>This value changes according to the value set in the IOV System Page Size register, so that the offset of the PBA register is on a page boundary. The values by page sizes are:<br>4 KB: 0x400<br>8 KB: 0x400<br>64 KB: 0x1000<br>256 KB: 0x4000<br>1 MB: 0x10000<br>4 MB: 0x40000 |
| 2:0  | 0x3     | RO   | PBA BIR<br>Indicates which one of a function's BARs, located beginning at 0x10 in configuration space, is used to map the function's MSI-X PBA into memory space.<br>A BIR value of three indicates that the PBA is mapped in BAR 3.                                                                                                                                                                                                                                                                                               |

## 9.7.2.2 PCIe Capability Registers

The device control and device status registers have some fields that are specific per VF.

**Table 9-26 Device Control (0xA8; RW)**

| Bits | R/W | Default | Description                                         |
|------|-----|---------|-----------------------------------------------------|
| 0    | RO  | 0b      | Correctable Error Reporting Enable<br>Zero for VFs. |
| 1    | RO  | 0b      | Non-Fatal Error Reporting Enable<br>Zero for VFs.   |

**Table 9-26 Device Control (0xA8; RW) (Continued)**

| Bits  | R/W | Default | Description                                               |
|-------|-----|---------|-----------------------------------------------------------|
| 2     | RO  | 0b      | Fatal Error Reporting Enable<br>Zero for VFs.             |
| 3     | RO  | 0b      | Unsupported Request Reporting Enable<br>Zero for VFs.     |
| 4     | RO  | 0b      | Enable Relaxed Ordering<br>Zero for VFs.                  |
| 7:5   | RO  | 0b      | Max Payload Size<br>Zero for VFs.                         |
| 8     | RO  | 0b      | Extended Tag field Enable<br>Not implemented in the I350. |
| 9     | RO  | 0b      | Phantom Functions Enable<br>Not implemented in the I350.  |
| 10    | RO  | 0b      | Auxiliary Power PM Enable<br>Zero for VFs.                |
| 11    | RO  | 0b      | Enable No Snoop<br>Zero for VFs.                          |
| 14:12 | RO  | 000b    | Max Read Request Size<br>Zero for VFs.                    |
| 15    | RW  | 0b      | Initiate Function Level Reset<br>Specific to each VF.     |

**Table 9-27 Device Status (0xAA; R/W1C)**

| Bits | R/W   | Default | Description                                                                                                                                                                                                                                                                              |
|------|-------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | R/W1C | 0b      | Correctable Detected<br>Indicates status of correctable error detection.                                                                                                                                                                                                                 |
| 1    | R/W1C | 0b      | Non-Fatal Error Detected<br>Indicates status of non-fatal error detection.                                                                                                                                                                                                               |
| 2    | R/W1C | 0b      | Fatal Error Detected<br>Indicates status of fatal error detection.                                                                                                                                                                                                                       |
| 3    | R/W1C | 0b      | Unsupported Request Detected<br>Indicates that the I350 received an unsupported request. This field is identical in all functions. The I350 cannot distinguish which function caused an error.                                                                                           |
| 4    | RO    | 0b      | Aux Power Detected<br>Zero for VFs.                                                                                                                                                                                                                                                      |
| 5    | RO    | 0b      | Transaction Pending<br>Specific per VF. When set, indicates that a particular function (PF or VF) has issued non-posted requests that have not been completed. A function reports this bit cleared only when all completions for any outstanding non-posted requests have been received. |
| 15:6 | RO    | 0x00    | Reserved                                                                                                                                                                                                                                                                                 |

## 9.7.3 Advanced Capabilities

### 9.7.3.1 Advanced Error Reporting Registers

The following registers in the AER capability have a different behavior in a VF function.

**Table 9-28    Uncorrectable Error Status (0x104; R/W1CS)**

| Bit Location | Attribute | Default Value | Description                                                                      |
|--------------|-----------|---------------|----------------------------------------------------------------------------------|
| 3:0          | RO        | 0000b         | Reserved                                                                         |
| 4            | RO        | 0b            | Data Link Protocol Error Status                                                  |
| 5            | RO        | 0b            | Surprise Down Error Status (Optional)                                            |
| 11:6         | RO        | 0x0           | Reserved                                                                         |
| 12           | R/W1CS    | 0b            | Poisoned TLP Status                                                              |
| 13           | RO        | 0b            | Flow Control Protocol Error Status                                               |
| 14           | R/W1CS    | 0b            | Completion Timeout Status                                                        |
| 15           | R/W1CS    | 0b            | Completer Abort Status                                                           |
| 16           | R/W1CS    | 0b            | Unexpected Completion Status                                                     |
| 17           | RO        | 0b            | Receiver Overflow Status                                                         |
| 18           | RO        | 0b            | Malformed TLP Status                                                             |
| 19           | RO        | 0b            | ECRC Error Status                                                                |
| 20           | R/W1CS    | 0b            | Unsupported Request Error Status<br>When caused by a function that claims a TLP. |
| 21           | RO        | 0b            | ACS Violation Status<br>Not supported in the I350.                               |
| 22           | RO        | 0b            | Uncorrectable Internal Error Status (Optional)<br>Not supported in the I350.     |
| 23           | RO        | 0b            | MC Blocked TLP Status (Optional)<br>Not supported in the I350.                   |
| 24           | RO        | 0b            | AtomicOps Egress Blocked Status (Optional)<br>Not supported in the I350.         |
| 25           | RO        | 0b            | TLP Prefix Blocked Error Status (Optional)<br>Not supported in the I350.         |
| 31:26        | RO        | 0x0           | Reserved                                                                         |

The Correctable Error Status register reports error status of individual correctable error sources on a PCIe device. When an individual error status bit is set to 1b, it indicates that a particular error occurred; software can clear an error status by writing a 1b to the respective bit. See the table below.

**Table 9-29    Correctable Error Status (0x110; R/W1CS)**

| Bit Location | Attribute | Default Value | Description                     |
|--------------|-----------|---------------|---------------------------------|
| 0            | RO        | 0b            | Receiver Error Status           |
| 5:1          | RO        | 0x0           | Reserved                        |

## 10 System Manageability

Network management is an important requirement in today's networked computer environment. Software-based management applications provide the ability to administer systems while the operating system is functioning in a normal power state (not in a pre-boot state or powered-down state). The Intel® System Management Bus (SMBus) Interface and the Network Controller Sideband Interface (NC-SI) fill the management void that exists when the operating system is not running or fully functional. This is accomplished by providing mechanisms by which manageability network traffic can be routed to and from a Management Controller (BMC).

This chapter describes the supported management interfaces and hardware configurations for platform system management. It describes the interfaces to an external BMC, the partitioning of platform manageability among system components, and the functionality provided by in each platform configuration.

### 10.1 Pass-Through (PT) Functionality

Pass-Through (PT) is the term used when referring to the process of sending and receiving Ethernet traffic over the sideband interface. The I350 has the ability to route Ethernet traffic to the host operating system as well as the ability to send Ethernet traffic over the sideband interface to an external BMC. See [Figure 10-1](#).

**Figure 10-1** Sideband Interface

The sideband interface provides a mechanism by which the I350 can be shared between the host and the BMC. By providing this sideband interface, the BMC can communicate with the LAN without requiring a dedicated Ethernet controller. The I350 supports two sideband interfaces:

- SMBus
- NC-SI

The usable bandwidth for either direction is up to 400 Kb/s when using SMBus and 100 Mb/s for the NC-SI interface. Only one mode of sideband can be active at any given time. The configuration is done using an EEPROM setting.

## 10.1.1 Pass Through Packet Routing

When an Ethernet packet reaches the I350, it is examined and compared to a number of configurable filters. These filters are configurable by the BMC and include, but not limited to, filtering on:

- MAC Address
- IP Address
- UDP/IP Ports
- VLAN Tags
- EtherType

If the incoming packet matches any of the configured filters, it is passed to the BMC. Otherwise it is not passed.

The packet filtering process is described in [Section 10.3](#).

## 10.2 Components of the Sideband Interface

There are two components to a sideband interface:

- Physical Layer
- Logical Layer

The BMC and the I350 must be in alignment for both components. An example issue: the NC-SI physical interface is based on the RMI interface, but there are differences between the devices at the physical level and the protocol layer is completely different.

### 10.2.1 Physical Layer

This is the electrical connection between the I350 and BMC.

#### 10.2.1.1 SMBus

The SMBus physical layer is defined by the SMBus specification. The interface is made up of two connections: Data and Clock. There is also an optional third connection: the Alert line. This line is used by the I350 to notify the BMC that there is data available for reading. Refer to the SMBus specification for details.

### 10.2.1.2 NC-SI

The I350 uses the DMTF standard Sideband Interface. This interface consists of 6 lines for transmission and reception of Ethernet packets and two optional lines for arbitration among more than one physical network controller.

The physical layer of NC-SI is very similar to the RMI interface, although not an exact duplicate. Refer to the NC-SI specification for details of the differences.

## 10.2.2 Logical Layer

### 10.2.2.1 Legacy SMBus

The protocol layer for SMBus consists of commands the BMC issues to configure filtering for I350 management traffic and the reading and writing of Ethernet frames over the SMBus interface. There is no industry standard protocol for sideband traffic over SMBus. The protocol layer for SMBus on the I350 is Intel proprietary. The Legacy SMBus protocol is described in [Section 10.5](#).

### 10.2.2.2 NC-SI

The DMTF also defines the protocol layer for the NC-SI interface. NC-SI compliant devices are required to implement a minimum set of commands. The specification also provides a mechanism for vendors to add additional capabilities through the use of OEM commands. Intel OEM NC-SI commands for the I350 are discussed in this document. For information on base NC-SI commands, see the NC-SI specification.

NC-SI traffic can run on top of two different Physical layers:

4. NC-SI Physical layer as described in [Section 10.2.1.2](#).
5. MCTP over SMBus. This protocol allows control and traffic over SMBus of a NIC or a LOM device. The MCTP protocol is described in [Section 10.7](#).

The I350 exposes one NC-SI package with four channels, one per port. The I350 implements a type C NC-SI interface (Single package, common bus buffers and shared RX queue) as described in section 5.2 of the NC-SI specification. The arbitration between the channels inside the package is done internally.

The package ID can be set either from the NVM *Package ID* field in the NC-SI Configuration - Offset 0x06 NVM word ([Section 6.3.9.7](#)) or from SDP0 pins of port 0 and 1. In this case, the Package ID is {0,Port1.SDP0, Port0.SDP0}. The mode used is set by the *Read NCSI Package ID from SDP* field in the NC-SI Configuration - Offset 0x07 NVM word ([Section 6.3.9.8](#)). Note that when the package ID is set from the SDP pins, the used SDPs should be set as input in the relevant Software Defined Pins Control NVM words.

## 10.3 Packet Filtering

Since both the host operating system and BMC use the I350 to send and receive Ethernet traffic, there needs to be a mechanism by which incoming Ethernet packets can be identified as those that should be sent to the BMC rather than the host operating system.

There are two different types of filtering available. The first is filtering based upon the MAC address. With this filtering, the BMC has at least one dedicated MAC address and incoming Ethernet traffic with the matching MAC address(es) are passed to the BMC. This is the simplest filtering mechanism to utilize and it allows an BMC to receive all types traffic (including, but not limited to, IPMI, NFS, HTTP etc).

The other mechanism available utilizes a highly configurable mechanism by which packets can be filtered using a wide range of parameters. Using this method, an BMC can share a MAC address (and IP address, if desired) with the host OS and receive only specific Ethernet traffic. This method is useful if the BMC is only interested in specific traffic, such as IPMI packets.

### 10.3.1 Manageability Receive Filtering

This section describes the manageability receive packet filtering flow. Packet reception by the I350 can generate one of the following results:

- Discarded
- Sent to Host memory
- Sent to the external BMC
- Sent to both the BMC and Host memory

The decisions regarding forwarding of packets to the Host and to the BMC are separate and are configured through two sets of registers. However, the BMC may define some types of traffic as exclusive. This traffic will be forwarded only to the BMC, even if it passes the filtering process of the Host. These types of traffic are defined using the MNGONLY register.

An example of packets that might be necessary to send exclusively to the BMC might be specific TCP/UDP ports of a shared MAC address or a MAC address dedicated to the BMC. If the BMC configures the manageability filters to send these ports to the BMC, it should configure the settings to not send them to the Host, otherwise, these ports will be received and handled by the Host operating system.

The BMC controls the types of packets that it receives by programming receive manageability filters. The following filters are accessible to the BMC:

**Table 10-1 Filters Accessible to BMC**

| Filters                              | Functionality                                                | When Reset?             |
|--------------------------------------|--------------------------------------------------------------|-------------------------|
| Filters Enable                       | General configuration of the manageability filters           | Internal Power On Reset |
| Manageability Only                   | Enables routing of packets exclusively to the manageability. | Internal Power On Reset |
| Manageability Decision Filters [7:0] | Configuration of manageability decision filters              | Internal Power On Reset |
| MAC Address [3:0]                    | Four exact MAC manageability addresses                       | Internal Power On Reset |
| VLAN Filters [7:0]                   | Eight VLAN tag values                                        | Internal Power On Reset |
| UDP/TCP Port Filters [3:0]           | 8 destination port values                                    | Internal Power On Reset |
| Flexible 128 bytes TCO Filter        | Length values for one flex TCO filter                        | Internal Power On Reset |
| IPv4 and IPv6 Address Filters [3:0]  | IP address for manageability filtering                       | Internal Power On Reset |

All filtering capabilities are available on both the NC-SI and legacy SMBus interfaces. However, in NC-SI mode, in order to program part of the capabilities, the Intel OEM commands described in [Section 10.6.3](#) should be used.

All filters are reset only on Internal Power On Reset. Register filters that enable filters or functionality are also reset by firmware. These registers can be loaded from the EEPROM following a reset. See [Section 6.1](#) for description of the location in the EEPROM map.

The high-level structure of manageability filtering is done using two steps.

1. The packet is parsed and fields in the header are compared to programmed filters.
2. A set of decision filters are applied to the result of the first step.

Some general rules apply:

- Fragmented packets are passed to manageability but not parsed beyond the IP header.
- Packets with L2 errors (CRC, alignment, etc.) are not forwarded to the BMC.
- Packets longer than 2KB are filtered out.

The following sections describe the manageability filtering, followed by the final filtering rules.

The filtering rules are created by programming the decision filters as described in [Section 10.3.4](#).

## 10.3.2 L2 Filters

### 10.3.2.1 MAC and VLAN Filters

The manageability MAC filters allow comparison of the Destination MAC address to one of 4 filters defined in the *MMAH* and *MMAL* registers.

The VLAN filters allow comparison of the 12 bit VLAN tag to one of 8 filters defined in the *MAVTV* registers.

### 10.3.2.2 EtherType Filters

Manageability L2 EtherType filters allow filtering of received packets based on the Layer 2 EtherType field. The L2 type field of incoming packets is compared against the EtherType filters programmed in the Manageability EtherType Filter (*METF*; up to 4 filters); the result is incorporated into decision filters.

Each Manageability EtherType filter can be configured as pass (positive) or reject (negative) using a polarity bit. In order for the reverse polarity mode to be effective and block certain type of packets, the EtherType filter should be part of all the enabled decision filters.

An example for usage of L2 EtherType filters is to determine the destination of 802.1X control packets. The 802.1X protocol is executed at different times in either the management controller or by the Host. L2 EtherType filters are used to route these packets to the proper agent.

In addition to the flexible EtherType filters, the I350 supports 2 fixed EtherType filters used to block NC-SI control traffic and flow control traffic from reaching the manageability interface. The NC-SI EtherType is used for communication between the management controller on the NC-SI link and the I350. Packets coming from the network are not expected to carry this EtherType and such packets are blocked to prevent attacks on the management controller. Flow control packets should be consumed by the MAC and as such are not expected to be forwarded to the management interface.

**Note:** In order to get meaningful filtering of Ethertype packets, negative filters should be in the AND section. If more than one positive Ethertype filter is needed, then they should be set in the

OR section. A single positive Ethertype filter may be enabled both in the AND or in OR section.

## 10.3.3 L3/L4 Filtering

The manageability filtering stage combines checks done at previous stages with additional L3/L4 checks to make a the decision on whether to route a packet to the BMC. The following sections describe the manageability filtering done at layers L3/L4 and final filtering rules.

### 10.3.3.1 ARP Filtering

ARP filtering — The I350 supports filtering of ARP request packets (initiated externally) and ARP responses (to requests initiated by the BMC or Host).

In legacy SMBus mode, the ARP filters can be used as part of the ARP offload described in [Section 10.5.4](#). ARP offload is not specifically available when using NC-SI. However, the general filtering mechanism is utilized to filter incoming ARP traffic as requested using the Enable Broadcast Filtering NC-SI command.

### 10.3.3.2 Neighbor Discovery Filtering

The I350 supports filtering of the following Neighbor Discovery packets:

1. 0x86 (134d) - Router Advertisement.
2. 0x87 (135d) - Neighbor Solicitation.
3. 0x88 (136d) - Neighbor Advertisement.
4. 0x89 (137d) - Redirect.

In SMBus mode, there is specific Neighborhood Discovery filter that can be enabled. The NC-SI interface does not have a filter for this. However, the general filtering mechanism can be utilized to filter this type of traffic.

### 10.3.3.3 RMCP Filtering

The I350 supports filtering by fixed destination port numbers, port 0x26F and port 0x298. These ports are IANA reserved for RMCP.

In SMBus mode, there are filters that can be enabled for these ports. When using NC-SI, they are not specifically available. However, the general filtering mechanism can be utilized to filter incoming ARP traffic.

### 10.3.3.4 Flexible Port Filtering

The I350 implements 8 flex destination port filters. The I350 directs packets whose L4 destination port matches to the BMC. The BMC must ensure that only valid entries are enabled in the decision filters.

### 10.3.3.5 Flexible 128 Byte Filter

The I350 provides one flex TCO filter. This filter looks for a pattern match within the first 128 bytes of the packet. The BMC must ensure that only valid entries are enabled in decision filters.

Flex filters are temporarily disabled when read from or written to by the Host. Any packet received during a read or write operation is dropped. Filter operation resumes once the read or write access completes.

#### 10.3.3.5.1 Flexible Filter Structure

The filter is composed of the following fields:

1. Flexible Filter length — This field indicates the number of bytes in the packet header that should be inspected. The field also indicates the minimal length of packets inspected by the filter. Packet below that length will not be inspected. Valid values for this field are:  $8*n$ , where  $n=1...16$ .
2. Data — This is a set of up to 128 bytes comprised of values that header bytes of packets are tested against.
3. Mask — This is a set of 128 bits corresponding to the 128 data bytes that indicate for each corresponding byte if is tested against its corresponding byte. The general filter is 128 bytes that the BMC configures; all of these bytes may not be needed or used for the filtering, so the mask is used to indicate which of the 128 bytes are used for the filter.

Each filter tests the first 128 bytes (or less) of a packet, where not all bytes must necessarily be tested.

#### 10.3.3.5.2 TCO Filter Programming

Programming each filter is done using the following commands (NC-SI or SMBus) in a sequential manner:

1. Filter Mask and Length — This command configures the following fields:
  - a. Mask — A set of 16 bytes containing the 128 bits of the mask. Bit 0 of the first byte corresponds to the first byte on the wire.
  - b. Length — A 1-byte field indicating the length.
2. Filter Data — The filter data is divided into groups of bytes, described below:

| Group | Test Bytes |
|-------|------------|
| 0x0   | 0-29       |
| 0x1   | 30-59      |
| 0x2   | 60-89      |
| 0x3   | 90-119     |
| 0x4   | 120-127    |

Each group of bytes need to be configured using a separate command, where the group number is given as a parameter. The command has the following parameters:

- a. Group number — A 1-byte field indicating the current group addressed
- b. Data bytes — Up to 30 bytes of test-bytes for the current group

### 10.3.3.6 IP Address Filtering

The I350 supports filtering by IP address using IPv4 and IPv6 address filters. These are dedicated to manageability. Two modes are possible, depending on the value of the MANC. EN\_IPv4\_FILTER bit:

- EN\_IPv4\_FILTER = 0b: the I350 provides four IPv6 address filters.
- EN\_IPv4\_FILTER = 1b: the I350 provides three IPv6 address filters and four IPv4 address filters.

### 10.3.3.7 Checksum Filtering

If bit *MANC.EN\_XSUM\_FILTER* is set, the I350 directs packets to the BMC only if they pass L3/L4 checksum (if they exist) in addition to matching other filters previously described.

Enabling the XSUM filter when using the SMBus interface is accomplished by setting the *Enable XSUM Filtering to Manageability* bit within the Manageability Control (MANC) register. This is done using the Update Management Receive Filter Parameters command. See [Section 10.5.10.1.6](#).

To enable the XSUM filtering when using NC-SI, use the Enable Checksum Offloading command. See [Section 10.6.3.13](#).

## 10.3.4 Configuring Manageability Filters

There are a number of pre-defined filters that are available for the BMC to enable, such as ARPs and IPMI ports 298h 26Fh. These are generally enabled by setting the appropriate bit within the MANC register using specific commands.

For more advanced filtering needs, the BMC has the ability to configure a number of configurable filters. It is a two-step process to use these filters. They must first be configured and then enabled.

### 10.3.4.1 Manageability Decision Filters (MDEF and MDEF\_EXT)

Manageability decision filters are a set of eight filters, each with the same structure. The filtering rule for each decision filter is programmed by the BMC and defines which of the L2, VLAN, EtherType and L3/L4 filters participate in decision making. Any packet that passes at least one rule is directed to manageability and possibly to the Host.

With the I350, packets can also be filtered by EtherType. This is part of the Extended Manageability Decision Filters (MDEF\_EXT).

The inputs to each decision filter are:

- Packet passed a valid management L2 exact address filter.
- Packet is a broadcast packet.
- Packet has a VLAN header and it passed a valid manageability VLAN filter.
- Packet matched one of the valid IPv4 or IPv6 manageability address filters.
- Packet is a multicast packet.
- Packet passed ARP filtering (request or response).
- Packet passed neighbor solicitation filtering.
- Packet passed 0x298/0x26F port filter.

- Packet passed a valid flex port filter.
- Packet passed a valid flex TCO filter.
- Packet passed or failed an L2 EtherType filter.
- Packet passed or failed Flow Control or NC-SI L2 EtherType Discard filter.

The structure of each decision filter is shown in [Figure 10-2](#). A boxed number indicates that the input is conditioned by a mask bit defined in the MDEF register and MDEF\_EXT register for this rule. Decision filter rules are as follows:

- At least one bit must be set in a register. If all bits are cleared (MDEF/MDEF\_EXT = 0x0000), then the decision filter is disabled and ignored.
- All enabled AND filters must match for the decision filter to match. An AND filter not enabled in the MDEF/MDEF\_EXT registers is ignored. If an AND filter is preceded by a OR filter, then at least one of the enabled OR inputs must match for the filter to pass.
- If no OR filter is enabled in the register, the OR filters are ignored in the decision (the filter might still match).
- If one or more OR filters are enabled in the register, then at least one of the enabled OR filters must match for the decision filter to match.

**Figure 10-2 Manageability Decision Filters**

A decision filter (for any of the 8 filters) defines which of the above inputs is enabled as part of a filtering rule. The BMC programs two 32-bit registers per rule (MDEF[7:0] & MDEF\_EXT[7:0]) with the settings as described in [Section 8.21.6](#) and [Section 8.21.7](#). A set bit enables its corresponding filter to participate in the filtering decision.

### 10.3.4.2 Exclusive Traffic

The decisions regarding forwarding of packets to the Host for LAN traffic or to the LAN for Host traffic are independent from the management decision filters. However, the BMC may define some types of traffic as exclusive. The behavior for such traffic is defined by the using the bits corresponding to the decision filter in the *MNGONLY* register (one bit per each of the eight decision rules) and the *MDEF\_EXT.apply\_to\_host\_traffic* and *MDEF\_EXT.apply\_to\_network\_traffic* bits. Table 10-3 describes the behavior in each case. If one or more filters match the traffic and at least one of the filters is set as exclusive, the traffic is treated as exclusive.

**Table 10-3 Exclusive traffic behavior**

| traffic source | Filter match                                                                                               |                                             | Filter doesn't match                                         |
|----------------|------------------------------------------------------------------------------------------------------------|---------------------------------------------|--------------------------------------------------------------|
|                | MNGONLY = 0                                                                                                | MNGONLY = 1                                 | N/A                                                          |
| From network   | Traffic is forwarded to the manageability.<br>Traffic is forwarded to the Host according to Host filtering | Traffic is forwarded only to manageability. | Traffic is forwarded to the Host according to Host filtering |
| From Host      | Traffic is forwarded to the manageability and to the LAN                                                   | Traffic is forwarded only to manageability. | Traffic is forwarded to the LAN                              |

Any traffic matching any of the configurable filters (see Section 10.3.4.1) can be used as filters to pass traffic to the Host.

**Table 10-4 MNGONLY register description and usage**

| Bits | Description       | Default                                                                                                                                                                                                                   |
|------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | Decision Filter 0 | Determines if packets that have passed decision filter 0 are sent exclusively to the manageability path.                                                                                                                  |
| 1    | Decision Filter 1 | Determines if packets that have passed decision filter 1 are sent exclusively to the manageability path.                                                                                                                  |
| 2    | Decision Filter 2 | Determines if packets that have passed decision filter 2 are sent exclusively to the manageability path.                                                                                                                  |
| 3    | Decision Filter 3 | Determines if packets that have passed decision filter 3 are sent exclusively to the manageability path.                                                                                                                  |
| 4    | Decision Filter 4 | Determines if packets that have passed decision filter 4 are sent exclusively to the manageability path.                                                                                                                  |
| 5    | Unicast and Mixed | NC-SI mode: Determines if unicast and mixed packets are sent exclusively to the manageability path<br>SMBus mode: Determines if packets that have passed decision filter 5 are sent exclusively to the manageability path |
| 6    | Global Multicast  | NC-SI mode: Determines if multicast packets are sent exclusively to the manageability path<br>SMBus mode: Determines if packets that have passed decision filter 6 are sent exclusively to the manageability path         |
| 7    | Broadcast         | NC-SI mode: Determines if broadcast packets are sent exclusively to the manageability path<br>SMBus mode: Determines if ARP packets are sent exclusively to the manageability path                                        |
| 31:8 | Reserved          | Reserved                                                                                                                                                                                                                  |

When using the SMBus interface, the BMC enables these filters by issuing the Update Management Receive Filter Parameters command (see Section 10.5.10.1.6) with the parameter of 0x0F.

The MNGONLY is also configurable when using NC-SI using the Set Intel Filters — Manageability Only Command (see Section 10.6.3.5.3).

All manageability filters are controlled by the BMC only and not by the LAN device driver.

## 10.3.5 Possible Configurations

This section describes ways of using management filters. Actual usage may vary.

### 10.3.5.1 Dedicated MAC Packet Filtering

- Select one of the eight rules for dedicated MAC filtering.
- Load Host MAC address to one of the management MAC address filters and set the appropriate bit in field 3:0 of the *MDEF* register.
- Set other bits to qualify which packets are allowed to pass through. For example:
  - Load one or more management VLAN filters and set the appropriate bits in field 12:5 of the *MDEF* register to qualify the relevant manageability VLANs.
  - Set relevant bits in field 20:13 of the *MDEF* register to qualify with a match to one of the IP addresses.
  - Set any L3/L4 bits (bits 31:27 in the *MDEF* register and bits 23:16 in the *MDEF\_EXT* register) to filter using any set of L3/L4 filters.

### 10.3.5.2 Broadcast Packet Filtering

- Select one of the eight rules for broadcast filtering.
- Set bit 25 in the *MDEF* register of the decision rule to enforce broadcast filtering.
- Set other bits to qualify which broadcast packets are allowed to pass through. For example:
  - Set bit 5 in the *MDEF* register to filter with the first manageability VLAN.
  - Set relevant bits in field 20:13 of the *MDEF* register to qualify with a match to one of the IP addresses.
  - Set any L3/L4 bits (bits 31:27 in the *MDEF* register and bits 23:16 in the *MDEF\_EXT* register) to filter with any set of L3/L4 filters.

### 10.3.5.3 VLAN Packet Filtering

- Select one of the eight rules for VLAN filtering.
- Load one or more management VLAN filters and set the appropriate bits in field 12:5 of the *MDEF* register to qualify the relevant manageability VLANs.
- Set other bits to qualify which VLAN packets are allowed to pass through. For example:
  - Set any L3/L4 bits (bits 31:27 in the *MDEF* register and bits 23:16 in the *MDEF\_EXT* register) to filter using appropriate L3/L4 filter set.

### 10.3.5.4 IPv6 Filtering

IPv6 filtering is done using the following IPv6-specific filters:

- IP Unicast filtering — requires filtering for Link Local address and a Global address. Filtering setup might depend on whether or not the MAC address is shared with the Host or dedicated to manageability:
  - Dedicated MAC address (for example, dynamic address allocation with DHCP does not support multiple IP addresses for one MAC address). In this case, filtering can be done at L2 using two dedicated unicast MAC filters.

- Shared MAC address (for example, static address allocation sharing addresses with Host). In this case, filtering needs to be done at L3, requiring two IPv6 address filters, one per address.
- A neighbor Discovery filter — The I350 supports IPv6 neighbor Discovery protocol. Since the protocol relies on multicast packets, the I350 supports filtering of these packets. IPv6 multicast addresses are translated into corresponding Ethernet multicast addresses in the form of 33-33-xx-xx-xx-xx, where the last 32 bits of address are taken from the last 32 bits of the IPv6 multicast address. As a result, two direct MAC filters can be used to filter IPv6 solicited-node multicast packets as well as IPv6 all node multicast packets.

### 10.3.5.5 Receive Filtering with Shared IP

When using the SMBus interface, it is possible to share the Host MAC and IP address with the BMC. This functionality is also available when using NC-SI using Intel OEM commands.

When the BMC shares the MAC and IP address with the Host, receive filtering is based on identifying specific flows through port allocation. The following setting might be used:

- Select one of the eight rules for Dedicated MAC filtering.
- Load Host MAC address to one of the management MAC address filters and set the appropriate bit in field 3:0 of the *MDEF* register to enforce MAC address filtering using the MAC address.
- If VLAN is used for management, load one or more management VLAN filters and set the appropriate bits in field 12:5 of the *MDEF* register to qualify the relevant manageability VLANs.
- ARP filter/Neighbor Discovery filter is enabled when the BMC is responsible for handling the ARP protocol. Set bit 27 or bit 28 in the *MDEF* register for this functionality.
- Set other bits to qualify which packets are allowed to pass through. For example:
  - Set any L3/L4 bits (bits 31:27 in the *MDEF* register and bits 23:16 in the *MDEF\_EXT* register) to filter using the appropriate L3/L4 filters.

### 10.3.6 Determining Manageability MAC Address

If the BMC wishes to use a dedicated MAC address or configure the automatic ARP response mechanism (only available in SMBus mode), it may be beneficial for the BMC to be able to determine the MAC address used by the Host.

Both the NC-SI and SMBus interfaces provide an Intel OEM command to read the System MAC address.

A possible use for this is that the MAC address programmed at manufacturing time does not increment by one each time, but rather by two. In this way, the BMC can read the System MAC address and add one to it and be guaranteed of a unique MAC address.

Determining the IP address being used by the Host is beyond the scope of this document.

## 10.4 OS to BMC Traffic

### 10.4.1 Overview

Traditionally, the communication between a Host and the local BMC is not handled through the network interface and requires a dedicated interface such as an IPMI KCS interface. The I350 allows the Host and the local BMC communication via the regular pass-through interface, and thus allow management of a local console using the same interface used to manage any BMC in the network.

When this flow is used, the Host will send packets to the BMC through the network interface. The I350 will examine these packets and it will then decide if they should be forwarded to the BMC. On the inverse path, when the BMC sends a packet on the pass-through interface, the I350 will check if it should be forwarded to the network, the Host, or both. [Figure 10-3](#) describes the flow for OS to BMC traffic for the NC-SI over RMII case. OS2BMC is not available in legacy SMBus mode.

The OS to BMC flow can be enabled using the *OS2BMC enable* field for the relevant port in the OS 2 BMC configuration structure of the EEPROM.

**Figure 10-3 OS 2 BMC Diagram**

**Note:** This flow assumes that the BMC does not share a MAC address with the Host.

The OS to BMC flow is enabled only for ports enabled by the NC-SI “Enable Channel” command or via the *OS to BMC Enable* field for the relevant port in the OS-to-BMC configuration structure of the EEPROM.

OS2BMC traffic shall comply with NC-SI specifications and is therefore limited to maximum sized frames of 1536 bytes (in both directions).

## 10.4.2 Filtering

### 10.4.2.1 OS2BMC Filtering

When OS to BMC traffic is enabled, the filters used for network to BMC traffic are also used for OS to BMC traffic. Traffic considered as exclusive to the BMC (Relevant bit in MNGONLY is set) is also considered as exclusive to the BMC when sent from the Host and not forwarded to the network.

VM to VM switching is considered only for packets that are forwarded to the network by the OS to BMC filtering process. Thus a packet will be sent to the network only if it wasn't defined as exclusive by the manageability path and by the VM to VM switching.

The filtering of the BMC precedes the VM to VM filtering and thus a packet is candidate for VM to VM switching only if the OS to BMC filtering decided to send the packet to the network as described in [Figure 10-4](#).

**Figure 10-4 OS 2 BMC and VM to VM filtering**

### 10.4.2.2 Handling of OS to BMC Packets

All the regular transmit offloads are available for OS to BMC packets also.

### 10.4.2.3 BMC to OS Filtering

When OS to BMC is enabled, as with regular BMC transmit traffic, the port (OS or network) to which the packet is sent is fixed according to the source MAC address of the packet.

After that, the BMC traffic will be filtered according to the L2 Host filters of the selected port (as described in [Section 7.1.3](#)). According to the results of the filtering the packet can be forwarded to the OS, the network or both.

The following rules apply to the forwarding of OS packets:

If *BMC to net* is disabled, all the traffic from the BMC is sent to the Host.

If *BMC to host* is disabled, all the traffic from the BMC is sent to the network.

The packet will be forwarded only according to the destination MAC address and VLAN tag.

When working in non VMDq modes (*MRQC.Multiple Receive Queues Enable* field not equal 011b), unicast packets that matches one of the exact filters (*RAH/RAL*) are sent only to the Host. Other packets that passes the L2 Host filtering will be sent to both the Host and the network. Packets that do not pass the L2 filtering will be sent only to the network.

When working in VMDq mode (*MRQC.Multiple Receive Queues Enable* field =011b), if a packet passes L2 filtering, the forwarding decisions are based on the Tx switching algorithm described in [Section 7.8.3.5](#). A packet that does not pass L2 filtering is sent to the network.

Packets for which the *LVLAN* bit is set in the *VLVF* matching their VLAN are not forwarded to the host.

### 10.4.2.4 Queuing of Packets Received from the BMC.

The traffic of the BMC to the Host can be queued according to the following mechanisms.

1. VMDq - In this mode, the packets will be queued according to the destination MAC address and VLAN. This mode is enabled by setting the *MRQC.Multiple Receive Queues Enable* field to 011b
2. If the previous modes is not used, the packets are forwarded to queue *MRQC.Def\_Q*.

### 10.4.2.5 Offloads of Packets received from the BMC.

Packets received from the BMC and forwarded to the OS do not pass the same path as regular network packets. Thus parts of the offloads provided for the network packets are not available for the BMC packets. Packet received from the BMC are identified by the *RDESC.STATUS.BMC* bit.

The following list describes which offloads are available for BMC packets:

- CRC is checked and removed on the BMC packets. The *RDESC.STATUS.Strip CRC* will always be set for these packets.
- The RSS type and RSS hash are not calculated for BMC packets and are always set to zero.
- The header of BMC packets is never split.
- A fragmented BMC packet will not be detected by the hardware.
- The BMC packets are not detected as time sync packet. The *RDESC.STATUS.TS* will always be clear for these packets.
- The L3 and L4 checksum are not performed on these packets. The *L4I*, *IPCS*, *UDPCS*, and *UDPV* fields will always be cleared for these packets.

- In systems where the double VLAN feature is enabled (*CTRL\_EXT.EXT\_VLAN* is set), the VEXT bit is valid for BMC packets.

**Note:** In systems that uses double VLAN, the BMC is expected to send all packets (apart from NC-SI commands) with the outer VLAN included. Failing to do so may cause corruptions to the packet received by the OS

- The *RDESC.ERRORS* field is always cleared for these packets.

**Note:** Traffic sent from the BMC will not cause a PME event, even if it matches one of the wake-up filters set by the port.

### 10.4.3 Blocking of Network to BMC Flow

In some systems the BMC may have its own private connection to the network and may use the I350 port only for the OS to BMC traffic. In this case, the BMC to network flow should be blocked while enabling the OS to BMC and OS to network flows.

This can be done by clearing the *MANC.EN\_BMC2NET* bit for the relevant port. The BMC can control this functionality using the “Enable Network to BMC flow” and “Disable Network to BMC flow” NC-SI OEM commands. This can also be controlled using the *Network to BMC disable* field in the EEPROM “OS2BMC Configuration Structure”.

**Note:** When network to BMC flow is blocked and OS to BMC flow is enabled, the traffic from the BMC is sent to the OS only if it passes the host L2 filtering. Other packets are dropped. The OS traffic filtering is still done using the regular decision filters.

### 10.4.4 Statistics

Packets sent from the OS to the BMC should be counted by all statistical counters as packets sent by the OS. If they are sent to both the network and to the BMC, then they are counted once.

Packets sent from the BMC to the Host are counted as packets received by the Host. If they are sent to the Host and to the network, then they are counted both as received packets and as packet transmitted to the network.

In addition, the I350 supports the following statistical counters that measure just the BMC to OS and OS to BMC traffic:

- O2BGPTC - OS2BMC packets received by BMC
- O2BSPC - OS2BMC packets transmitted by OS
- B2OSPC - BMC2OS packets sent by BMC
- B2OGPRC - BMC2OS packets received by OS.

The driver can use these statistics to count packets dropped by the I350 during the transfer between the OS and the BMC.

See [Section 7.10.5](#) for details of the statistics hierarchy.

## 10.4.5 OS to BMC Enablement

The I350 supports the unified network software model for OS to BMC traffic, where the OS to BMC traffic is shared with the regular traffic. In this model, there is no need for a special configuration of the OS networking stack or the BMC stack, but if the link is down, then the OS to BMC communication is stopped.

In order to enable OS to BMC either:

- Enable OS2BMC in the port traffic type field in the Traffic type Parameters EEPROM word for the relevant port.
- Send an *EnableOS2BMC Flow* NC-SI OEM Command.

**Note:** When OS2BMC is enabled, OS shall avoid sending packets longer than 1.5KB to BMC. Such packets will be dropped.

## 10.5 SMBus Pass-Through Interface

SMBus is the system management bus defined by Intel. It is used in personal computers and servers for low-speed system management communications. This section describes how the SMBus interface operates in pass-through mode.

### 10.5.1 General

The SMBus sideband interface includes standard SMBus commands used for assigning a slave address and gathering device information as well as Intel proprietary commands used specifically for the pass-through interface.

### 10.5.2 Pass-Through Capabilities

This section details manageability capabilities the I350 provides while in SMBus mode. Pass-through traffic is carried by the sideband interface as described in [Section 10.1](#).

These services are not available in NC-SI mode.

When operating in SMBus mode, in addition to exposing a communication channel to the LAN for the BMC, the I350 provides the following manageability services to the BMC:

- ARP handling — The I350 can be programmed to auto-ARP replying for ARP request packets to reduce the traffic over the BMC interconnect.
- Default configuration of filters by EEPROM - When working in SMBus mode, the default values of the manageability receive filters can be set according to the PT LAN and flex TCO EEPROM structures.

### 10.5.3 Port to SMBus Mapping

The I350 is presented on the SMBus manageability link as four different devices (for example, via four different SMBus addresses on which each device is connected to a different LAN port). There is no logical connection between the four devices.

The fail-over between the LAN ports is done by the BMC (by sending/receiving packets through different devices). The status report to the BMC, ARP handling, DHCP, and other pass-through functionality are unique for each port and configured by the BMC.

## 10.5.4 Automatic Ethernet ARP Operation

The I350 can offload the Ethernet Address Resolution Protocol (ARP) for the BMC in order to reduce the bandwidth required on the SMBus link.

Automatic Ethernet ARP parameters are loaded from the EEPROM when the I350 is powered up or configured through the sideband management interface. The following parameters should be configured in order to enable ARP operation:

- ARP auto-reply enabled
- ARP IP address (to filter ARP packets)
- ARP MAC addresses (for ARP responses)

These are all configurable over the sideband interface using the advanced version of the Receive Enable command.

When an ARP request packet is received and ARP auto-reply is enabled, the I350 checks the targeted IP address (after the packet has passed L2 checks and ARP checks). If the targeted IP matches the IP configuration for the I350, it replies with an ARP response.

The I350 responds to ARP request targeted to the ARP IP address with the configured ARP MAC address. In case that there is no match, the I350 silently discards the packets. If the I350 is not configured to do auto-ARP response, it can be configured to forward the ARP packets to the BMC (which can respond to ARP requests).

When the external BMC uses the same IP and MAC address of the OS, the ARP operation should be coordinated with the Host operating system.

**Note:** If sharing the MAC and IP with the Host operating system is possible, the I350 provides the ability to read the stem MAC address, allowing the BMC to share the MAC address. There is no mechanism however provided by the I350 to read the IP address. The Host OS (or an agent within) and BMC must coordinate the sharing of IP addresses.

### 10.5.4.1 ARP Packet Formats

**Table 10-5 ARP Request Packet**

| Offset     | # Of bytes | Field                             | Value (In Hex) | Action  |
|------------|------------|-----------------------------------|----------------|---------|
| 0          | 6          | Destination Address               |                | Compare |
| 6          | 6          | Source Address                    |                | Stored  |
| 12         | S=(0/4)    | Possible VLAN Tag                 |                | Stored  |
| 12 + S     | D=(0/8)    | Possible Length + LLC/SNAP Header |                | Stored  |
| 12 + S + D | 2          | Type                              | 0806           | Compare |
| 14+ S + D  | 2          | HW Type                           | 0001           | Compare |
| 16+ S + D  | 2          | Protocol Type                     | 0800           | Compare |

**Table 10-5 ARP Request Packet (Continued)**

|           |   |                         |                |         |
|-----------|---|-------------------------|----------------|---------|
| 18+ S + D | 1 | Hardware Size           | 06             | Compare |
| 19+ S + D | 1 | Protocol Address Length | 04             | Compare |
| 20+ S + D | 2 | Operation               | 0001           | Compare |
| 22+ S + D | 6 | Sender HW Address       | -              | Stored  |
| 28+ S + D | 4 | Sender IP Address       | -              | Stored  |
| 32+ S + D | 6 | Target HW Address       | -              | Ignore  |
| 38+ S + D | 4 | Target IP Address       | ARP IP address | Compare |

**Table 10-6 ARP Response Packet**

| Offset     | # of bytes | Field                             | Value                         |
|------------|------------|-----------------------------------|-------------------------------|
| 0          | 6          | Destination Address               | ARP Request Source Address    |
| 6          | 6          | Source Address                    | Programmed from EEPROM or BMC |
| 12         | S=(0/4)    | Possible VLAN Tag                 | From ARP Request              |
| 12 + S     | D=(0/8)    | Possible Length + LLC/SNAP Header | From ARP Request              |
| 12 + S + D | 2          | Type                              | 0x0806                        |
| 14+ S + D  | 2          | HW Type                           | 0x0001                        |
| 16+ S + D  | 2          | Protocol Type                     | 0x0800                        |
| 18+ S + D  | 1          | Hardware Size                     | 0x06                          |
| 19+ S + D  | 1          | Protocol Address Length           | 0x04                          |

## 10.5.5 SMBus Transactions

This section gives a brief overview of the SMBus protocol. Following is an example for a format of a typical SMBus transaction.

|          |               |          |          |           |          |                  |          |          |
|----------|---------------|----------|----------|-----------|----------|------------------|----------|----------|
| <b>1</b> | <b>7</b>      | <b>1</b> | <b>1</b> | <b>8</b>  | <b>1</b> | <b>8</b>         | <b>1</b> | <b>1</b> |
| S        | Slave Address | Wr       | A        | Command   | A        | PEC              | A        | P        |
|          | 1100 001      | 0        | 0        | 0000 0010 | 0        | [Data Dependent] | 0        |          |

The top row of the table identifies the bit length of the field in a decimal bit count. The middle row (bordered) identifies the name of the fields used in the transaction. The last row appears only with some transactions, and lists the value expected for the corresponding field. This value can be either hexadecimal or binary.

The SMBus controller is a master for some transactions and a slave for others. The differences are identified in this document.

Shorthand field names are listed in [Table 10-8](#) and are fully defined in the SMBus specification.

**Table 10-8 Shorthand Field Names**

| Field Name | Definition                         |
|------------|------------------------------------|
| S          | SMBus START Symbol                 |
| P          | SMBus STOP Symbol                  |
| PEC        | Packet Error Code                  |
| A          | ACK (Acknowledge)                  |
| N          | NACK (Not Acknowledge)             |
| Rd         | Read Operation (Read Value = 1b)   |
| Wr         | Write Operation (Write Value = 0b) |

### 10.5.5.1 SMBus Addressing

The SMBus is presented as four SMBus devices on the SMBus (four addresses). All pass-through functionality is duplicated on the SMBus address, where each SMBus address is connected to a different LAN port. Note that it is not permitted to configure different ports to the same SMBus address. When a LAN function is disabled, the corresponding SMBus address is not presented to the BMC.

SMBus addresses (enabled from the EEPROM) can be re-assigned using the SMBus ARP protocol.

In addition to the SMBus address values, all parameters of the SMBus (SMBus channel selection, address mode, and address enable) can be set only through EEPROM configuration. Note that the EEPROM is read at the I350's power up and resets.

All SMBus addresses should be in Network Byte Order (NBO); MSB first.

### 10.5.5.2 SMBus ARP Functionality

The I350 supports the SMBus ARP protocol as defined in the SMBus 2.0 specification. The I350 is a persistent slave address device so its SMBus address is valid after power-up and loaded from the EEPROM. The I350 supports all SMBus ARP commands defined in the SMBus specification both general and directed.

SMBus ARP capability can be disabled through the EEPROM.

### 10.5.5.3 SMBus ARP Flow

SMBus ARP flow is based on the status of two flags:

- AV (Address Valid): This flag is set when the I350 has a valid SMBus address.
- AR (Address Resolved): This flag is set when the I350 SMBus address is resolved (SMBus address was assigned by the SMBus ARP process).

These flags are internal I350 flags and are not exposed to external SMBus devices.

Since the I350 is a Persistent SMBus Address (PSA) device, the AV flag is always set, while the AR flag is cleared after power up until the SMBus ARP process completes. Since AV is always set, the I350 always has a valid SMBus address.

When the SMBus master needs to start an SMBus ARP process, it resets (in terms of ARP functionality) all devices on SMBus by issuing either Prepare to ARP or Reset Device commands. When the I350 accepts one of these commands, it clears its AR flag (if set from previous SMBus ARP process), but not its AV flag (the current SMBus address remains valid until the end of the SMBus ARP process).

Clearing the AR flag means that the I350 responds to SMBus ARP transactions that are issued by the master. The SMBus master issues a Get UDID command (general or directed) to identify the devices on the SMBus. The I350 always responds to the Directed command and to the General command only if its AR flag is not set.

After the Get UDID, The master assigns the I350 SMBus address by issuing an Assign Address command. The I350 checks whether the UDID matches its own UDID and if it matches, it switches its SMBus address to the address assigned by the command (byte 17). After accepting the Assign Address command, the AR flag is set and from this point (as long as the AR flag is set), the I350 does not respond to the Get UDID General command. Note that all other commands are processed even if the AR flag is set. The I350 stores the SMBus address that was assigned in the SMBus ARP process in the EEPROM, so at the next power up, it returns to its assigned SMBus address.

Figure 10-5 shows the I350 SMBus ARP flow.

Figure 10-5 SMBus ARP Flow

### 10.5.5.4 SMBus ARP UDID Content

The UDID provides a mechanism to isolate each device for the purpose of address assignment. Each device has a unique identifier. The 128-bit number is comprised of the following fields:

| 1 Byte                | 1 Byte                | 2 Bytes   | 2 Bytes   | 2 Bytes           | 2 Bytes             | 2 Bytes             | 4 Bytes               |
|-----------------------|-----------------------|-----------|-----------|-------------------|---------------------|---------------------|-----------------------|
| Device Capabilities   | Version/Revision      | Vendor ID | Device ID | Interface         | Subsystem Vendor ID | Subsystem Device ID | Vendor Specific ID    |
| See notes that follow | See notes that follow | 0x8086    | 0x151F    | 0x0004/<br>0x0024 | 0x0000              | 0x0000              | See notes that follow |
| MSB                   |                       |           |           |                   |                     |                     | LSB                   |

Where:

|                   |                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Vendor ID:        | The device manufacturer's ID as assigned by the SBS Implementers' Forum or the PCI SIG.<br>Constant value: 0x8086                                                              |
| Device ID:        | The device ID as assigned by the device manufacturer (identified by the Vendor ID field).<br>Constant value: 0x151F                                                            |
| Interface:        | Identifies the protocol layer interfaces supported over the SMBus connection by the device.<br>Bits 3:0 = 0x4 indicates SMBus Version 2.0<br>Bit 5 (ASF bit) = 1 in MCTP mode. |
| Subsystem Fields: | These fields are not supported and return zeros.                                                                                                                               |

| 0b           | 0b           | 001b         |   |   | See the following table |   |     |
| MSB          |              |              |   |   |                         |   | LSB |

Silicon Revision ID:

| Silicon Version | Revision ID |
|-----------------|-------------|
| A0              | 000b        |
| A1              | 001b        |
| A2              | 010b        |

Vendor Specific ID: Four LSB bytes of the device Ethernet MAC address of the relevant port. The device Ethernet address is taken from the EEPROM. Note that in the I350 there are four MAC addresses (one for each port).

| 1 Byte              | 1 Byte              | 1 Byte              | 1 Byte              |
|---------------------|---------------------|---------------------|---------------------|
| MAC Address, Byte 3 | MAC Address, Byte 2 | MAC Address, Byte 1 | MAC Address, Byte 0 |
| MSB                 |                     |                     | LSB                 |

### 10.5.5.5 SMBus ARP in Multi/Single Mode

The I350 responds as four SMBus devices having four sets of AR/AV flags (one for each port). The I350 responds four times to the SMBus ARP master, once each for each port. All SMBus addresses are taken from the SMBus ARP address word in the EEPROM.

Note that the Unique Device Identifier (UDID) is different for the four ports in the version ID field (which represents the MAC address and is different for the four ports). It is recommended that the I350 first respond as port 0, and only when an address is assigned, then start responding as port 1,2 and 3 to the Get UDID command.

### 10.5.5.6 Concurrent SMBus Transactions

The SMBus interface is single threaded. Thus, concurrent SMBus transactions are not permitted. Once a transaction is started, it must be completed before additional transaction can be initiated.

A transaction is defined as:

- All SMBus commands used to receive a packet.
- All SMBus commands used to send a packet.
- The read and write SMBus commands used as part of read parameters described in [Section 10.5.10.2](#).
- The single write SMBus commands described in [Section 10.5.10.1](#).

## 10.5.6 SMBus Notification Methods

The I350 supports three methods of notifying the BMC that it has information that needs to be read by the BMC:

- SMBus alert - Refer to [Section 10.5.6.1](#).
- Asynchronous notify - Refer to [Section 10.5.6.2](#).
- Direct receive - refer to [Section 10.5.6.3](#).

The notification method used by the I350 can be configured from the SMBus using the Receive Enable command. This default method is set by the EEPROM in the Pass-Through Init field.

The following events cause the I350 to send a notification event to the BMC:

- Receiving a LAN packet that is designated to the BMC
- The Firmware was reset and requires re-initialization if values other than the EEPROM defaults should be configured.
- Receiving a Request Status command from the BMC initiates a status response.

- The I350 is configured to notify the BMC upon status changes (by setting the EN\_STA bit in the Receive Enable Command) and one of the following events happen:
  - TCO Command Aborted
  - Link Status changed
  - Power state change
  - Thermal Sensor Event

There can be cases where the BMC is hung and not responding to the SMBus notification. The I350 has a time-out value (defined in the EEPROM) to avoid hanging while waiting for the notification response. If the BMC does not respond until the time out expires, the notification is de-asserted and all pending data is silently discarded.

Note that the SMBus notification time-out value can only be set in the EEPROM. The BMC cannot modify this value.

### 10.5.6.1 SMBus Alert and Alert Response Method

The SMBus Alert# (SMBALERT\_N) signal is an additional SMBus signal that acts as an asynchronous interrupt signal to an external SMBus master. The I350 asserts this signal each time it has a message that it needs the BMC to read and if the chosen notification method is the SMBus alert method. Note that the SMBus alert method is an open-drain signal which means that other devices besides the I350 can be connected on the same alert pin. As a result, the BMC needs a mechanism to distinguish between the alert sources.

The BMC can respond to the alert by issuing an ARA Cycle command to detect the alert source device. The I350 responds to the ARA cycle with its own SMBus slave address (if it was the SMBus alert source) and de-asserts the alert when the ARA cycle is completes. Following the ARA cycle, the BMC issues a read command to retrieve the I350 message.

Some BMCs do not implement the ARA cycle transaction. These BMCs respond to an alert by issuing a Read command to the I350 (0xC0/0xD0 or 0xDE). The I350 always responds to a Read command, even if it is not the source of the notification. The default response is a status transaction. If the I350 is the source of the SMBus Alert, it replies the read transaction and then de-asserts the alert after the command byte of the read transaction.

**Note:** In SMBus Alert mode, the SMBALERT\_N pin is used for notification. In multiple-address mode, all devices generate alerts on events that are independent of each other.

The ARA cycle is an SMBus receive byte transaction to SMBus Address 0001-100b. Note that the ARA transaction does not support PEC. The ARA transaction format is as follows:

|          |                        |          |          |                                   |          |          |          |
|----------|------------------------|----------|----------|-----------------------------------|----------|----------|----------|
| <b>1</b> | <b>7</b>               | <b>1</b> | <b>1</b> | <b>8</b>                          | <b>1</b> | <b>1</b> | <b>1</b> |
| S        | Alert Response Address | Rd       | A        | Slave Device Address              |          | A        | P        |
|          | 0001 100               | 1        | 0        | Manageability Slave SMBus Address | 0        | 1        |          |

### 10.5.6.2 Asynchronous Notify Method

When configured using the asynchronous notify method, the I350 acts as a SMBus master and notifies the BMC by issuing a modified form of the write word transaction. The asynchronous notify transaction SMBus address and data payload is configured using the Receive Enable command or using the EEPROM defaults. Note that the asynchronous notify is not protected by a PEC byte.

|          |                   |          |          |                         |          |          |     |
|----------|-------------------|----------|----------|-------------------------|----------|----------|-----|
| <b>1</b> | <b>7</b>          | <b>1</b> | <b>1</b> | <b>7</b>                | <b>1</b> | <b>1</b> |     |
| S        | Target Address    | Wr       | A        | Sending Device Address  |          | A        | ... |
|          | BMC Slave Address | 0        | 0        | MNG Slave SMBus Address | 0        | 0        |     |

|               |          |                |          |          |
|---------------|----------|----------------|----------|----------|
| <b>8</b>      | <b>1</b> | <b>8</b>       | <b>1</b> | <b>1</b> |
| Data Byte Low | A        | Data Byte High | A        | P        |
| Interface     | 0        | Alert Value    | 0        |          |

The target address and data byte low/high is taken from the Receive Enable command or EEPROM configuration.

### 10.5.6.3 Direct Receive Method

If configured, the I350 has the capability to send a message it needs to transfer to the external BMC as a master over the SMBus instead of alerting the BMC and waiting for it to read the message.

The message format follows. Note that the command that is used is the same command that is used by the external BMC in the Block Read command. The opcode that the I350 puts in the data is also the same as it put in the Block Read command of the same functionality. The rules for the *F* and *L* flags (bits) are also the same as in the Block Read command.

|          |                   |          |          |            |           |                                 |          |     |
|----------|-------------------|----------|----------|------------|-----------|---------------------------------|----------|-----|
| <b>1</b> | <b>7</b>          | <b>1</b> | <b>1</b> | <b>1</b>   | <b>1</b>  | <b>6</b>                        | <b>1</b> |     |

|          | BMC Slave Address | 0        | 0        | First Flag | Last Flag | Receive TCO Command<br>01 0000b | 0        |     |

|            |          |             |          |     |          |             |          |          |
|------------|----------|-------------|----------|-----|----------|-------------|----------|----------|
| <b>8</b>   | <b>1</b> | <b>8</b>    | <b>1</b> |     | <b>1</b> | <b>8</b>    | <b>1</b> | <b>1</b> |
| Byte Count | A        | Data Byte 1 | A        | ... | A        | Data Byte N | A        | P        |
| N          | 0        |             | 0        |     | 0        |             | 0        |          |

### 10.5.7 Receive TCO Flow

The I350 is used as a channel for receiving packets from the network link and passing them to the external BMC. The BMC configures the I350 to pass these specific packets to the BMC. Once a full packet is received from the link and identified as a manageability packet that should be transferred to the BMC, the I350 starts the receive TCO flow to the BMC.

The I350 uses the SMBus notification method to notify the BMC that it has data to deliver. Since the packet size might be larger than the maximum SMBus fragment size, the packet is divided into fragments, where the I350 uses the maximum fragment size allowed in each fragment (configured via the EEPROM). The last fragment of the packet transfer is always the status of the packet. As a result, the packet is transferred in at least two fragments. The data of the packet is transferred as part of the receive TCO LAN packet transaction.

When SMBus alert is selected as the BMC notification method, the I350 notifies the BMC on each fragment of a multi-fragment packet. When asynchronous notify is selected as the BMC notification method, the I350 notifies the BMC only on the first fragment of a received packet. It is the BMC's responsibility to read the full packet including all the fragments.

Any timeout on the SMBus notification results in discarding the entire packet. Any NACK by the BMC causes the fragment to be re-transmitted to the BMC on the next Receive Packet command.

The maximum size of the received packet is limited by the I350 hardware to 1536 bytes. Packets larger than 1536 bytes are silently discarded. Any packet smaller than 1536 bytes is processed.

## 10.5.8 Transmit TCO Flow

The I350 is used as the channel for transmitting packets from the external BMC to the network link. The network packet is transferred from the BMC over the SMBus and then, when fully received by the I350, is transmitted over the network link.

In quad-address mode, each SMBus address is connected to a different LAN port. When a packet is received during a SMBus transaction using SMBus address #0, it is transmitted to the network using LAN port #0; it is transmitted through LAN port #1 if received on SMBus address #1, etc.

The I350 supports packets up to an Ethernet packet length of 1536 bytes. Since SMBus transactions can only be up to 240 bytes in length, packets might need to be transferred over the SMBus in more than one fragment. This is achieved using the *F* and *L* bits in the command number of the transmit TCO packet Block Write command. When the *F* bit is set, it is the first fragment of the packet. When the *L* bit is set, it is the last fragment of the packet. When both bits are set, the entire packet is in one fragment. The packet is sent over the network link only after all its fragments are received correctly over the SMBus. The maximum SMBus fragment size is defined within the EEPROM and cannot be changed by the BMC.

The minimum packet length defined by the 802.3 spec is 64 bytes. The I350 pads packets that are less than 64 bytes to meet the specification requirements (there is no need for the external BMC to pad packets less than 64 bytes). If the packet sent by the BMC is larger than 1536 bytes, the I350 silently discards the packet.

The I350 calculates the L2 CRC on the transmitted packet and adds its four bytes at the end of the packet. Any other packet field (such as XSUM or VLAN) must be calculated and inserted by the BMC (the I350 does not change any field in the transmitted packet, other than adding padding and CRC bytes).

If the network link is down when the I350 has received the last fragment of the packet from the BMC, it silently discards the packet. Note that any link down event during the transfer of any packet over the SMBus does not stop the operation since the I350 waits for the last fragment to end to see whether the network link is up again.

### 10.5.8.1 Transmit Errors in Sequence Handling

Once a packet is transferred over the SMBus from the BMC to the I350, the *F* and *L* flags should follow specific rules. The *F* flag defines the first fragment of the packet; the *L* flag that the transaction contains the last fragment of the packet. Table 10-9 lists the different flag options in transmit packet transactions.

**Table 10-9 Flag Options During Transmit Packet Transactions**

| Previous | Current   | Action/Notes                                                                                                                                       |
|----------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Last     | First     | Accept both.                                                                                                                                       |
| Last     | Not First | Error for the current transaction. Current transaction is discarded and an abort status is asserted.                                               |
| Not Last | First     | Error in previous transaction. Previous transaction (until previous First) is discarded. Current packet is processed. No abort status is asserted. |
| Not Last | Not First | Process the current transaction.                                                                                                                   |

**Note:** Since every other Block Write command in TCO protocol has both *F* and *L* flags on, they cause flushing any pending transmit fragments that were previously received. When running the TCO transmit flow, no other Block Write transactions are allowed in between the fragments.

### 10.5.8.2 TCO Command Aborted Flow

The I350 indicates to the BMC an error or an abort condition by setting the *TCO Abort* bit (See Section 10.5.10.2.2) in the general status. The I350 might also be configured to send a notification to the BMC (see Section 10.5.10.1.3.3).

Following is a list of possible error and abort conditions:

- Any error in the SMBus protocol (NACK, SMBus timeouts, etc.).
- Any error in compatibility between required protocols to specific functionality (for example, RX Enable command with a byte count not equal to 1/14, as defined in the command specification).
- If the I350 does not have space to store the transmitted packet from the BMC (in its internal buffer space) before sending it to the link, the packet is discarded and the external BMC is notified via the *Abort* bit.
- Error in the *F/L* bit sequence during multi-fragment transactions.
- An internal reset to the I350's firmware.

## 10.5.9 SMBus ARP Transactions

All SMBus ARP transactions include the PEC byte.

### 10.5.9.1 Prepare to ARP

This command clears the *Address Resolved* flag (set to false). It does not affect the status or validity of the dynamic SMBus address and is used to inform all devices that the ARP master is starting the ARP process:

| 1 | 7             | 1  | 1 | 8         | 1 | 8                      | 1 | 1 |
|---|---------------|----|---|-----------|---|------------------------|---|---|
| S | Slave Address | Wr | A | Command   | A | PEC                    | A | P |
|   | 1100 001      | 0  | 0 | 0000 0001 | 0 | [Data Dependent Value] | 0 |   |

### 10.5.9.2 Reset Device (General)

This command clears the *Address Resolved* flag (set to false). It does not affect the status or validity of the dynamic SMBus address.

| 1 | 7             | 1  | 1 | 8         | 1 | 8                      | 1 | 1 |
|---|---------------|----|---|-----------|---|------------------------|---|---|
| S | Slave Address | Wr | A | Command   | A | PEC                    | A | P |
|   | 1100 001      | 0  | 0 | 0000 0010 | 0 | [Data Dependent Value] | 0 |   |

### 10.5.9.3 Reset Device (Directed)

The Command field is NACKed if bits 7:1 do not match the current SMBus address. This command clears the *Address Resolved* flag (set to false) and does not affect the status or validity of the dynamic SMBus address.

| 1 | 7             | 1  | 1 | 8                          | 1 | 8                      | 1 | 1 |
|---|---------------|----|---|----------------------------|---|------------------------|---|---|
| S | Slave Address | Wr | A | Command                    | A | PEC                    | A | P |
|   | 1100 001      | 0  | 0 | Targeted Slave Address   0 | 0 | [Data Dependent Value] | 0 |   |

### 10.5.9.4 Assign Address

This command assigns SMBus address. The address and command bytes are always acknowledged.

The transaction is aborted (NACKed) immediately if any of the UDID bytes is different from I350 UDID bytes. If successful, the manageability system internally updates the SMBus address. This command also sets the *Address Resolved* flag (set to true).

| 1 | 7             | 1  | 1 | 8         | 1 | 8          | 1 |     |
|---|---------------|----|---|-----------|---|------------|---|-----|
| S | Slave Address | Wr | A | Command   | A | Byte Count | A | ... |
|   | 1100 001      | 0  | 0 | 0000 0100 | 0 | 0001 0001  | 0 |     |

| 8                  | 1 | 8            | 1 | 8            | 1 | 8            | 1 |     |
|--------------------|---|--------------|---|--------------|---|--------------|---|-----|
| Data 1             | A | Data 2       | A | Data 3       | A | Data 4       | A | ... |
| UDID Byte 15 (MSB) | 0 | UDID Byte 14 | 0 | UDID Byte 13 | 0 | UDID Byte 12 | 0 |     |

|              |   |              |   |             |   |             |   |     |
|--------------|---|--------------|---|-------------|---|-------------|---|-----|
| 8            | 1 | 8            | 1 | 8           | 1 | 8           | 1 |     |
| Data 5       | A | Data 6       | A | Data 7      | A | Data 8      | A | ... |
| UDID Byte 11 | 0 | UDID Byte 10 | 0 | UDID Byte 9 | 0 | UDID Byte 8 | 0 |     |

|             |   |             |   |             |   |     |
|-------------|---|-------------|---|-------------|---|-----|
| 8           | 1 | 8           | 1 | 8           | 1 |     |
| Data 9      | A | Data 10     | A | Data 11     | A | ... |
| UDID Byte 7 | 0 | UDID Byte 6 | 0 | UDID Byte 5 | 0 |     |

|             |   |             |   |             |   |             |   |     |
|-------------|---|-------------|---|-------------|---|-------------|---|-----|
| 8           | 1 | 8           | 1 | 8           | 1 | 8           | 1 |     |
| Data 12     | A | Data 13     | A | Data 14     | A | Data 15     | A | ... |
| UDID Byte 4 | 0 | UDID Byte 3 | 0 | UDID Byte 2 | 0 | UDID Byte 1 | 0 |     |

|                   |   |                  |   |                        |   |   |
|-------------------|---|------------------|---|------------------------|---|---|
| 8                 | 1 | 8                | 1 | 8                      | 1 | 1 |
| Data 16           | A | Data 17          | A | PEC                    | A | P |
| UDID Byte 0 (LSB) | 0 | Assigned Address | 0 | [Data Dependent Value] | 0 |   |

**Note:** The Assigned address is not checked by the I350, so if the bus master assigns an invalid address (for example a reserved address), the I350 will use it as its address. The only exception is address 0xC2 used as part of the SMBus process.

### 10.5.9.5 Get UDID (General and Directed)

The general get UDID SMBus transaction supports a constant command value of 0x03 and, if directed, supports a Dynamic command value equal to the dynamic SMBus address.

If the SMBus address has been resolved (*Address Resolved* flag set to true), the manageability system does not acknowledge (NACK) this transaction. If it's a General command, the manageability system always acknowledges (ACKs) as a directed transaction.

This command does not affect the status or validity of the dynamic SMBus address or the *Address Resolved* flag.

| S | Slave Address | Wr | A | Command   | A | S | ... |
|---|---------------|----|---|-----------|---|---|-----|
|   | 1100 001      | 0  | 0 | See Below | 0 |   |     |

|               |    |   |            |   |     |
|---------------|----|---|------------|---|-----|
| 7             | 1  | 1 | 8          | 1 |     |
| Slave Address | Rd | A | Byte Count | A | ... |
| 1100 001      | 1  | 0 | 0001 0001  | 0 |     |

|                    |   |              |   |              |   |              |   |     |
|--------------------|---|--------------|---|--------------|---|--------------|---|-----|
| 8                  | 1 | 8            | 1 | 8            | 1 | 8            | 1 |     |
| Data 1             | A | Data 2       | A | Data 3       | A | Data 4       | A | ... |
| UDID Byte 15 (MSB) | 0 | UDID Byte 14 | 0 | UDID Byte 13 | 0 | UDID Byte 12 | 0 |     |

|              |   |              |   |             |   |             |   |     |
|--------------|---|--------------|---|-------------|---|-------------|---|-----|
| 8            | 1 | 8            | 1 | 8           | 1 | 8           | 1 |     |
| Data 5       | A | Data 6       | A | Data 7      | A | Data 8      | A | ... |
| UDID Byte 11 | 0 | UDID Byte 10 | 0 | UDID Byte 9 | 0 | UDID Byte 8 | 0 |     |

|             |   |             |   |             |   |     |
|-------------|---|-------------|---|-------------|---|-----|
| 8           | 1 | 8           | 1 | 8           | 1 |     |
| Data 9      | A | Data 10     | A | Data 11     | A | ... |
| UDID Byte 7 | 0 | UDID Byte 6 | 0 | UDID Byte 5 | 0 |     |

|             |   |             |   |             |   |             |   |     |
|-------------|---|-------------|---|-------------|---|-------------|---|-----|
| 8           | 1 | 8           | 1 | 8           | 1 | 8           | 1 |     |
| Data 12     | A | Data 13     | A | Data 14     | A | Data 15     | A | ... |
| UDID Byte 4 | 0 | UDID Byte 3 | 0 | UDID Byte 2 | 0 | UDID Byte 1 | 0 |     |

|                   |   |                      |   |                        |    |   |
|-------------------|---|----------------------|---|------------------------|----|---|
| 8                 | 1 | 8                    | 1 | 8                      | 1  | 1 |
| Data 16           | A | Data 17              | A | PEC                    | ~Ä | P |
| UDID Byte 0 (LSB) | 0 | Device Slave Address | 0 | [Data Dependent Value] | 1  |   |

The Get UDID command depends on whether or not this is a Directed or General command.

The General Get UDID SMBus transaction supports a constant command value of 0x03.

The Directed Get UDID SMBus transaction supports a Dynamic command value equal to the dynamic SMBus address with the LSB bit set.

**Note:** Bit 0 (LSB) of Data byte 17 is always 1b.

## 10.5.10 SMBus Pass-Through Transactions

This section details commands (both read and write) that the I350 SMBus interface supports for pass-through.

### 10.5.10.1 Write SMBus Transactions

This section details the commands that the BMC can send to the I350 over the SMBus interface. The SMBus write transactions table lists the different SMBus write transactions supported by the I350.

| TCO Command                      | Transaction | Command                                   | Fragmentation | Section                     |
|----------------------------------|-------------|-------------------------------------------|---------------|-----------------------------|
| Transmit Packet                  | Block Write | First: 0x84<br>Middle: 0x04<br>Last: 0x44 | Multiple      | <a href="#">10.5.10.1.1</a> |
| Transmit Packet                  | Block Write | Single: 0xC4                              | Single        | <a href="#">10.5.10.1.1</a> |
| Request Status                   | Block Write | Single: 0xDD                              | Single        | <a href="#">10.5.10.1.2</a> |
| Receive Enable                   | Block Write | Single: 0xCA                              | Single        | <a href="#">10.5.10.1.3</a> |
| Force TCO                        | Block Write | Single: 0xCF                              | Single        | <a href="#">10.5.10.1.4</a> |
| Management Control               | Block Write | Single: 0xC1                              | Single        | <a href="#">10.5.10.1.5</a> |
| Update MNG RCV Filter Parameters | Block Write | Single: 0xCC                              | Single        | <a href="#">10.5.10.1.6</a> |
| Set Thermal Sensor Configuration | Block Write | Single: 0xCB (opcode = 1)                 | Single        | <a href="#">10.5.10.1.7</a> |
| Perform Thermal Sensor Action    | Block Write | Single: 0xCB (opcode = 2)                 | Single        | <a href="#">10.5.10.1.8</a> |

#### 10.5.10.1.1 Transmit Packet Command

The Transmit Packet command behavior is detailed in [Section 10.5.8](#). The Transmit Packet fragments have the following format.

The payload length is limited to the maximum payload length set in the EEPROM. If the overall packet length is bigger than 1536 bytes, the packet is silently discarded.

| Function                 | Command | Byte Count | Data 1          | ... | Data N          |
|--------------------------|---------|------------|-----------------|-----|-----------------|
| Transmit first fragment  | 0x84    | N          | Packet data MSB | ... | Packet data LSB |
| Transmit middle fragment | 0x04    |            |                 |     |                 |
| Transmit last fragment   | 0x44    |            |                 |     |                 |
| Transmit single fragment | 0xC4    |            |                 |     |                 |

#### 10.5.10.1.2 Request Status Command

An external BMC can initiate a request to read I350 manageability status by sending a Request Status command. When received, the I350 initiates a notification to an external BMC when status is ready. After this, the external controller will be able to read the status, by issuing a read status command (see [Section 10.5.10.2.2](#)).

The format is as follows:

| Function       | Command | Byte Count | Data 1 |
|----------------|---------|------------|--------|
| Request Status | 0xDD    | 1          | 0      |

### 10.5.10.1.3 Receive Enable Command

The Receive Enable command is a single fragment command used to configure the I350. This command has two formats: short, 1-byte legacy format (providing backward compatibility with previous components) and long, 14-byte advanced format (allowing greater configuration capabilities). The Receive Enable command format is as follows:

| Function                | CMD  | Byte Count | Data 1               | Data 2       | ... | Data 7       | Data 8      | ... | Data 11     | Data 12        | Data 13       | Data 14          |
|-------------------------|------|------------|----------------------|--------------|-----|--------------|-------------|-----|-------------|----------------|---------------|------------------|
| Legacy Receive Enable   | 0xCA | 1          | Receive Control Byte | -            | ... | -            | -           | ... | -           | -              | -             | -                |
| Advanced Receive Enable |      | 14 (0x0E)  |                      | MAC Addr MSB |     | MAC Addr LSB | IP Addr MSB |     | IP Addr LSB | BMC SMBus Addr | I/F Data Byte | Alert Value Byte |

**Table 10-10** Receive Control Byte

| Field   | Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RCV_EN  | 0      | Receive TCO Enable.<br>0b: Disable receive TCO packets.<br>1b: Enable Receive TCO packets.<br>Setting this bit enables all manageability receive filtering operations. Enabling specific filters is done via the EEPROM or through special configuration commands.<br><b>Note:</b> When the <i>RCV_EN</i> bit is cleared, all receive TCO functionality is disabled, not just the packets that are directed to the BMC (also auto ARP packets). |
| RCV_ALL | 1      | Receive All Enable.<br>0b: Disable receiving all packets.<br>1b: Enable receiving all packets.<br>Forwards all packets received over the wire that passed L2 filtering to the external BMC. This flag has no effect if bit 0 (Enable TCO packets) is disabled.                                                                                                                                                                                  |
| EN_STA  | 2      | Enable Status Reporting.<br>0b: Disable status reporting.<br>1b: Enable status reporting.                                                                                                                                                                                                                                                                                                                                                       |

**Table 10-10 Receive Control Byte**

| Field      | Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EN_ARP_RES | 3      | <p>Enable ARP Response.</p> <p>0b: Disable the I350 ARP response.</p> <p>The I350 treats ARP packets as any other packet, for example, packet is forwarded to the BMC if it passed other (non-ARP) filtering.</p> <p>1b: Enable the I350 ARP response.</p> <p>The I350 automatically responds to all received ARP requests that match its IP address. Note that setting this bit does not change the Rx filtering settings. Appropriate Rx filtering to enable ARP request packets to reach the BMC should be set by the BMC or by the EEPROM.</p> <p>The BMC IP address is provided as part of the Receive Enable message (bytes 8:11). If a short version of the command is used, the I350 uses IP address configured in the most recent long version of the command in which the EN_ARP_RES bit was set. If no such previous long command exists, then the I350 uses the IP address configured in the EEPROM as ARP Response IPv4 Address in the pass-through LAN configuration structure.</p> <p>If the CBDM bit is set, the I350 uses the BMC dedicated MAC address in ARP response packets. If the CBDM bit is not set, the BMC uses the Host MAC address.</p> |
| NM         | 5:4    | <p>Notification Method. Define the notification method the I350 uses.</p> <p>00b: SMBUS Alert.</p> <p>01b: Asynchronous notify.</p> <p>10b: Direct receive.</p> <p>11b: Not supported.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Reserved   | 6      | Reserved. Must be set to 1b.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| CBDM       | 7      | <p>Configure the BMC Dedicated MAC Address.</p> <p><b>Note:</b> This bit should be 0b when the RCV_EN bit (bit 0) is not set.</p> <p>0b: The I350 shares the MAC address for MNG traffic with the Host MAC address, which is specified in EEPROM words 0x0-0x2.</p> <p>1b: The I350 uses the BMC dedicated MAC address as a filter for incoming receive packets.</p> <p>The BMC MAC address is set in bytes 2-7 in this command.</p> <p>If a short version of the command is used, the I350 uses the MAC address configured in the most recent long version of the command in which the CBDM bit was set.</p> <p>When the dedicated MAC address feature is activated, the I350 uses the following registers to filter in all the traffic addressed to the BMC MAC. BMC should not modify these registers:</p> <p>Manageability Decision Filter – MDEF7 (and corresponding bit 7 in Management Only traffic Register – MNGONLY)</p> <p>Manageability MAC Address Low – MMAL[3]</p> <p>Manageability MAC Address High – MMAH[3]</p>                                                                                                                                    |

#### 10.5.10.1.3.1 Management MAC Address (Data Bytes 7:2)

Ignored if the CBDM bit is not set. This MAC address is used to configure the dedicated MAC address. In addition, it is used in the ARP response packet when the EN\_ARP\_RES bit is set. This MAC address is also used when CBDM bit is set in subsequent short versions of this command.

#### 10.5.10.1.3.2 Management IP Address (Data Bytes 11:8)

This IP address is used to filter ARP request packets.

#### 10.5.10.1.3.3 Asynchronous Notification SMBus Address (Data Byte 12)

This address is used for the asynchronous notification SMBus transaction and for direct receive.

#### 10.5.10.1.3.4 Interface Data (Data Byte 13)

Interface data byte used in asynchronous notification.

### 10.5.10.1.3.5 Alert Value Data (Data Byte 14)

Alert Value data byte used in asynchronous notification.

### 10.5.10.1.4 Force TCO Command

This command causes the I350 to perform a TCO reset, TCO isolate, or Firmware Reset

**TCO Reset:** if Force TCO reset is enabled in the EEPROM. The force TCO reset clears the data path (Rx/Tx) of the I350 to enable the BMC to transmit/receive packets through the I350. Force TCO reset is asserted only to the port related to the SMBus address the command. This command should only be used when the BMC is unable to transmit receive and suspects that the I350 is inoperable. The command also causes the LAN device driver to unload. It is recommended to perform a system restart to resume normal operation.

**TCO isolate:** if TCO isolate is enabled in the EEPROM (See [Section 6.3.7.3](#)). The TCO Isolate command will disable PCIe write operations to the LAN port. If TCO Isolate is disabled in EEPROM the I350 does not execute the command but sends a response to the BMC with successful completion. Following TCO Isolate management sets *MANC.TCO\_Isolate* to 1.

**Firmware Reset:** This command will cause re-initialization of all the manageability functions and re-load of manageability related EEPROM words (e.g. Firmware patch code).

The I350 considers the Force TCO reset command as an indication that the operating system is hung and clears the *DRV\_LOAD* flag. The Force TCO command format is as follows:

| Function        | Command | Byte Count | Data 1   |
|-----------------|---------|------------|----------|
| Force TCO Reset | 0xCF    | 1          | TCO Mode |

Where TCO Mode is:

| Field                       | Bit(s) | Description                                                                                                                                                                                                                                             |
|-----------------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DO_TCO_RST                  | 0      | Perform TCO Reset.<br>0b: Do nothing.<br>1b: Perform TCO reset.                                                                                                                                                                                         |
| DO_TCO_ISOLATE <sup>1</sup> | 1      | Do TCO Isolate<br>0b = Enable PCIe write access to LAN port.<br>1b = Isolate Host PCIe write operation to the port<br>Note: Should be used for debug only.                                                                                              |
| RESET_MGMT                  | 2      | Reset manageability; re-load manageability EEPROM words.<br>0b = Do nothing<br>1b = Issue firmware reset to manageability.<br>Setting this bit generates a one-time firmware reset. Following the reset, management related data from EEPROM is loaded. |
| Reserved                    | 7:3    | Reserved (set to 0x00).                                                                                                                                                                                                                                 |

1. TCO Isolate Host Write operation enabled in EEPROM.

### 10.5.10.1.5 Management Control

This command is used to set generic manageability parameters. The parameters list is shown in [Table 10-11](#). The command is 0xC1 stating that it is a Management Control command. The first data byte is the parameter number and the data afterwards (length and content) are parameter specific as shown in Management Control Command Parameters/Content.

**Note:** If the parameter that the BMC sets is not supported by the I350. The I350 does not NACK the transaction. After the transaction ends, the I350 discards the data and asserts a transaction abort status.

The Management Control command format is as follows:

| Function           | Command | Byte Count | Data 1           | Data 2              | ... | Data N |
|--------------------|---------|------------|------------------|---------------------|-----|--------|
| Management Control | 0xC1    | N          | Parameter Number | Parameter Dependent |     |        |

**Table 10-11 Management Control Command Parameters/Content**

| Parameter        | #    | Parameter Data                                                                                                                                                                                                                                                                                                |
|------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Keep PHY Link Up | 0x00 | A single byte parameter:<br>Data 2:<br>Bit 0: Set to indicate that the PHY link for this port should be kept up throughout system resets. This is useful when the server is reset and the BMC needs to keep connectivity for a manageability session.<br>Bit [7:1] Reserved.<br>0b: Disabled.<br>1b: Enabled. |

#### 10.5.10.1.6 Update Management Receive Filter Parameters

This command is used to set the manageability receive filters parameters. The command is 0xCC. The first data byte is the parameter number and the data that follows (length and content) are parameter specific as listed in management RCV filter parameters.

If the parameter that the BMC sets is not supported by the I350, then the I350 does not NACK the transaction. After the transaction ends, the I350 discards the data and asserts a transaction abort status.

The update management RCV receive filter parameters command format is as follows:

| Function                               | Command | Byte Count | Data 1           | Data 2              | ... | Data N |
|----------------------------------------|---------|------------|------------------|---------------------|-----|--------|
| Update Manageability Filter Parameters | 0xCC    | N          | Parameter Number | Parameter Dependent |     |        |

[Table 10-12](#) lists the different parameters and their content.

**Table 10-12 Management Receive Filter Parameters**

| Parameter       | Number | Parameter Data                                                                                                                                                                                                                                    |
|-----------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filters Enables | 0x1    | Defines the generic filters configuration. The structure of this parameter is four bytes as the Manageability Control (MANC) register.<br><b>Note:</b> The general filter enable is in the Receive Enable command that enables receive filtering. |

**Table 10-12 Management Receive Filter Parameters**

| Parameter                            | Number | Parameter Data                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MNGONLY configuration                | 0xF    | This parameter defines which of the packets types identified as manageability packets in the receive path will never be directed to the Host memory.<br>Data 2:5: MNGONLY register bytes - Data 2 is the MSB                                                                                                                       |
| Flex Filter 0 Enable Mask and Length | 0x10   | Flex Filter 0 Mask.<br>Data 17:2 = Mask. Bit 0 in data 2 is the first bit of the mask.<br>Data 19:18 = Reserved. Should be set to 00b.<br>Data 20 = Flexible filter length.                                                                                                                                                        |
| Flex Filter 0 Data                   | 0x11   | Data 2 — Group of flex filter's bytes:<br>0x0 = bytes 0-29<br>0x1 = bytes 30-59<br>0x2 = bytes 60-89<br>0x3 = bytes 90-119<br>0x4 = bytes 120-127<br>Data 3:32 = Flex filter data bytes. Data 3 is LSB.<br>Group's length is not a mandatory 30 bytes; it might vary according to filter's length and must NOT be padded by zeros. |
| Decision Filters                     | 0x61   | Five bytes are required to load the manageability decision filters (MDEF).<br>Data 2: Decision filter number.<br>Data 3: MSB of MDEF register for this decision filter.<br>...<br>Data 6: LSB of MDEF register for this decision filter.                                                                                           |
| VLAN Filters                         | 0x62   | Three bytes are required to load the VLAN tag filters.<br>Data 2: VLAN filter number.<br>Data 3: MSB of VLAN filter.<br>Data 4: LSB of VLAN filter.                                                                                                                                                                                |
| Flex Port Filters                    | 0x63   | Three bytes are required to load the manageability flex port filters.<br>Data 2: Flex port filter number.<br>Data 3: MSB of flex port filter.<br>Data 4: LSB of flex port filter.                                                                                                                                                  |
| IPv4 Filters                         | 0x64   | Five bytes are required to load the IPv4 address filter.<br>Data 2: IPv4 address filter number (3:0).<br>Data 3: LSB of IPv4 address filter.<br>...<br>Data 6: MSB of IPv4 address filter.                                                                                                                                         |
| IPv6 Filters                         | 0x65   | 17 bytes are required to load the IPv6 address filter.<br>Data 2 — IPv6 address filter number (3:0).<br>Data 3 — LSB of IPv6 address filter.<br>...<br>Data 18 — MSB of IPv6 address filter.                                                                                                                                       |
| MAC Filters                          | 0x66   | Seven bytes are required to load the MAC address filters.<br>Data 2 — MAC address filters pair number (3:0).<br>Data 3 — MSB of MAC address.<br>...<br>Data 8: LSB of MAC address.                                                                                                                                                 |
| EtherType Filters                    | 0x67   | 5 bytes to load EtherType Filters (METF)<br>Data 2 — METF filter index (valid values are 0, 1, 2, 3)<br>Data 3 — MSB of METF<br>...<br>Data 6 — LSB of METF                                                                                                                                                                        |

**Table 10-12 Management Receive Filter Parameters**

| Parameter                | Number | Parameter Data                                                                                                                                                                                                                                                                                                                                                                     |

**Table 10-13 Filter Enable Parameters**

| Bit   | Name                         | Description                                                                                                                                                                                                                                                                           |
|-------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16:0  | Reserved                     | Reserved                                                                                                                                                                                                                                                                              |
| 17    | RCV_TCO_EN                   | TCO Receive Traffic Enabled.<br>When bit is set receive traffic to the manageability block is enabled.<br>This bit should be set only if at least one of EN_BMC2OS or EN_BMC2NET bits are set.<br>This bit is usually set using the receive enable command (see Section 10.5.10.1.3). |
| 18    | KEEP_PHY_LINK_UP             | Block PHY reset and power state changes. When this bit is set the PHY reset and power state changes does not get to the PHY, This bit can not be written unless Keep_PHY_Link_Up_En EEPROM bit is set.                                                                                |
| 22:19 | Reserved                     | Reserved                                                                                                                                                                                                                                                                              |
| 23    | Enable Xsum Filtering to MNG | When this bit is set, only packets that pass the L3 and L4 checksum are send to the manageability block.                                                                                                                                                                              |
| 24    | Enable IPv4 Address Filters  | When set, the last 128 bits of the MIPAF register are used to store four IPv4 addresses for IPv4 filtering. When cleared, these bits store a single IPv6 filter.                                                                                                                      |
| 25    | FIXED_NET_TYPE               | Fixed net type: If set, only packets matching the net type defined by the NET_TYPE field passes to manageability. Otherwise, both tagged and un-tagged packets can be forwarded to the manageability engine.                                                                          |
| 26    | NET_TYPE                     | NET TYPE:<br>0b = pass only un-tagged packets.<br>1b = pass only VLAN tagged packets.<br>Valid only if FIXED_NET_TYPE is set.                                                                                                                                                         |
| 31:27 | Reserved                     | Reserved.                                                                                                                                                                                                                                                                             |

### 10.5.10.1.7 Set Thermal Sensor Configuration

This command sets the thermal sensor configuration for threshold “Index” in direction “Direction”.

Where the threshold is measured in “unit types” and the “Actions” field describes the actions to activate upon crossing of the threshold in the requested direction according to [Table 10-44](#).

Direction is encoded as follow:

- 0 = High Going
- 1 = Low Going

| Function                         | Command | Byte Count | Data 1       | Data 2 | Data      |
|----------------------------------|---------|------------|--------------|--------|-----------|
| Set Thermal Sensor Configuration | 0xCB    | 14         | Opcode (0x1) | Index  | Direction |

| Data 4-5  | Data 6-9             | Data 10-13          | Data 14    |
|-----------|----------------------|---------------------|------------|
| Threshold | Actions "Going High" | Actions "Going Low" | Hysteresis |

### 10.5.10.1.8 Perform Thermal Sensor Action

This command executes actions immediately.

The "Actions" field describes the actions to activate according to [Table 10-44](#).

| Function                      | Command | Byte Count | Data 1       | Data 2-5 |
|-------------------------------|---------|------------|--------------|----------|
| Perform Thermal Sensor Action | 0xCB    | 5          | Opcode (0x2) | Actions  |

### 10.5.10.2 Read SMBus Transactions

This section details the pass-through read transactions that the BMC can send to the I350 over SMBus.

SMBus read transactions lists the different SMBus read transactions supported by the I350. All the read transactions are compatible with SMBus read block protocol format.

**Table 10-14 SMBus Read Transactions**

| TCO Command                           | Transaction | Command              | Opcode                                                  | Fragments | Section                     |
|---------------------------------------|-------------|----------------------|---------------------------------------------------------|-----------|-----------------------------|
| Receive TCO Packet                    | Block Read  | 0xD0 or 0xC0         | First: 0x90<br>Middle: 0x10<br>Last <sup>1</sup> : 0x50 | Multiple  | <a href="#">10.5.10.2.1</a> |
| Read Status                           | Block Read  | 0xD0 or 0xC0 or 0xDE | Single: 0xDD                                            | Single    | <a href="#">10.5.10.2.2</a> |
| Get System MAC Address                | Block Read  | 0xD4                 | Single: 0xD4                                            | Single    | <a href="#">10.5.10.2.3</a> |
| Read Management Parameters            | Block Read  | 0xD1                 | Single: 0xD1                                            | Single    | <a href="#">10.5.10.2.4</a> |
| Read Management RCV Filter Parameters | Block Read  | 0xCD                 | Single: 0xCD                                            | Single    | <a href="#">10.5.10.2.5</a> |
| Read Receive Enable Configuration     | Block Read  | 0xDA                 | Single: 0xDA                                            | Single    | <a href="#">10.5.10.2.6</a> |
| Get Thermal Sensor Capabilities       | Block Read  | 0xDB (index = 0)     | Single: 0xDB                                            | Single    | <a href="#">10.5.10.2.6</a> |
| Get Thermal Sensor Configuration      | Block Read  | 0xDB (index = 1)     | Single: 0xDB                                            | Single    | <a href="#">10.5.10.2.6</a> |
| Get Thermal Sensor Status             | Block Read  | 0xDB (index = 2)     | Single: 0xDB                                            | Single    | <a href="#">10.5.10.2.6</a> |

1. The last fragment of the receive TCO packet is the packet status.

0xC0 or 0xD0 commands are used for more than one payload. If BMC issues these read commands, and the I350 has no pending data to transfer, it always returns as default opcode 0xDD with the I350 status and does not NACK the transaction.

If an SMBus quick read command is received, it is handled as a I350 Request Status command (See [Section 10.5.10.1.2](#) for details).

### 10.5.10.2.1 Receive TCO LAN Packet Transaction

The BMC uses this command to read packets received on the LAN and its status. When the I350 has a packet to deliver to the BMC, it asserts the SMBus notification for the BMC to read the data (or direct receive). Upon receiving notification of the arrival of a LAN receive packet, the BMC begins issuing a Receive TCO packet command using the block read protocol.

A packet can be transmitted to the BMC in at least two fragments (at least one for the packet data and one for the packet status). As a result, BMC should follow the *F* and *L* bit of the op-code.

The op-code can have these values:

- 0x90 — First Fragment
- 0x10 — Middle Fragment
- When the opcode is 0x50, this indicates the last fragment of the packet, which contains packet status.

If a notification timeout is defined (in the EEPROM) and the BMC does not finish reading the whole packet within the timeout period, since the packet has arrived, the packet is silently discarded.

Following is the receive TCO packet format and the data format returned from the I350.

| Function           | Command      |
|--------------------|--------------|
| Receive TCO Packet | 0xC0 or 0xD0 |

| Function                    | Byte Count | Data 1 (Op-Code) | Data 2                                    | ... | Data N           |
|-----------------------------|------------|------------------|-------------------------------------------|-----|------------------|
| Receive TCO First Fragment  | N          | 0x90             | Packet Data Byte                          | ... | Packet Data Byte |
| Receive TCO Middle Fragment |            | 0x10             |                                           |     |                  |
| Receive TCO Last Fragment   | 17 (0x11)  | 0x50             | See <a href="#">Section 10.5.10.2.1.1</a> |     |                  |

#### 10.5.10.2.1.1 Receive TCO LAN Status Payload Transaction

This transaction is the last transaction that the I350 issues when a packet received from the LAN is transferred to the BMC. The transaction contains the status of the received packet.

The format of the status transaction is as follows:

| Function                | Byte Count | Data 1 (Op-Code) | Data 2 – Data 17 (Status Data) |
|-------------------------|------------|------------------|--------------------------------|
| Receive TCO Long Status | 17 (0x11)  | 0x50             | See Below                      |

The status is 16 bytes where byte 0 (bits 7:0) is set in Data 2 of the status and byte 15 in Data 17 of the status. [Table 10-15](#) lists the content of the status data.

**Table 10-15 TCO LAN Packet Status Data**

| Name          | Bits   | Description                                                                                   |
|---------------|--------|-----------------------------------------------------------------------------------------------|
| Packet Length | 13:0   | Packet length including CRC, only 14 LSB bits.                                                |
| Packet status | 36:14  | See <a href="#">Table 10-16</a>                                                               |
| Reserved      | 42:37  | Reserved                                                                                      |
| Error         | 47:43  | See <a href="#">Table 10-17</a>                                                               |
| VLAN          | 63:48  | The two bytes of the VLAN header tag.                                                         |
| Reserved      | 67:64  | Reserved                                                                                      |
| Packet type   | 80:68  | See <a href="#">Table 10-19</a>                                                               |
| Reserved      | 84:81  | Reserved                                                                                      |
| MNG status    | 127:85 | See <a href="#">Table 10-20</a> . This field should be ignored if Receive TCO is not enabled, |

The meaning of the bits inside of each field can be found in [Section 7.1.4.2](#).

**Table 10-16 Packet Status Info**

| Field        | Bit(s) | Description                                     |
|--------------|--------|-------------------------------------------------|
| LAN#         | 22:21  | Indicates the source port of the packet         |
| Reserved     | 20     | Reserved                                        |
| VP           | 19     | VLAN Stripped –insertion of VLAN TAG is needed. |
| VEXT         | 18     | Additional VLAN present in packet               |
| Reserved     | 17:15  | Reserved                                        |
| Reserved     | 14:12  | Reserved                                        |
| CRC stripped | 11     | Insertion of CRC is needed.                     |
| Reserved     | 10:6   | Reserved                                        |
| UDPV         | 5      | UDP checksum valid                              |
| Reserved     | 4:3    | Reserved                                        |
| IPCS         | 2      | Ipv4 Checksum Calculated on packet              |
| L4I          | 1      | L4 (TCP/UDP) Checksum calculated on packet      |
| UDPCS        | 0      | UDP checksum calculated on packet               |

**Table 10-17 Error Status Info**

| Field    | Bit(s) | Description                 |
|----------|--------|-----------------------------|
| RXE      | 4      | RX Data Error               |
| IPE      | 3      | Ipv4 Checksum Error         |
| L4E      | 2      | L4 (TCP/UDP) Checksum Error |
| Reserved | 1:0    | Reserved                    |

**Table 10-19 Packet type**

| Bit Index | Bit 11 = 0b                             | Bit 11 = 1b (L2 packet)                                                                                                                |
|-----------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 12        | VLAN packet indication                  |                                                                                                                                        |
| 11        | Packet matched one of the ETQF filters. |                                                                                                                                        |
| 10:8      | Reserved                                | Reserved                                                                                                                               |
| 7         | Reserved                                | Reserved                                                                                                                               |
| 6         |                                         |                                                                                                                                        |
| 5         |                                         |                                                                                                                                        |
| 4         |                                         |                                                                                                                                        |
| 3         |                                         |                                                                                                                                        |
| 2         |                                         |                                                                                                                                        |
| 1         |                                         |                                                                                                                                        |
| 0         |                                         | EtherType - ETQF register index that matches the packet. Special types might be defined for 1588, 802.1X, or any other requested type. |

**Table 10-20 MNG Status**

| Name                                  | Bits  | Description                                                                                                                     |
|---------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------|
| Decision Filter match                 | 42:35 | Set when there is a match to one of the Decision filters                                                                        |
| IPv4/IPv6 match                       | 34    | Set when there is an IPv6 match and cleared when there's an IPV4 match. This bit is valid only if bit 33 (IP match bit) is set. |
| IP address match                      | 33    | Set when there is a match to any of the IP address filters                                                                      |
| IP address Index                      | 32:31 | Set when there is a match to the IP filter number. (IPv4 or IPv6)                                                               |
| Flex TCO filter match                 | 30    | Set when there is a match to the Flex port filter                                                                               |
| Reserved                              | 29:27 | Reserved                                                                                                                        |
| L4 port match                         | 26    | Set when there is a match to any of the UDP / TCP port filters                                                                  |
| L4 port Filter Index                  | 25:19 | Indicate the flex filter number                                                                                                 |
| Exact Address match                   | 18    | Set when there is a match to any of the 4 Exact MAC addresses.                                                                  |
| Exact Address Index                   | 17:15 | Indicates which of the 4 Exact MAC addresses match the packet. Valid only if the Exact Address match is set.                    |
| MNG VLAN Address Match                | 14    | Set when the MNG packet matches one of the MNG VLAN filters                                                                     |
| Pass MNG VLAN Filter Index            | 13:11 | Indicates which of the Vlan filters match the packet.                                                                           |
| Reserved                              | 10:8  | Reserved                                                                                                                        |
| Pass ARP req / ARP resp               | 7     | Set when the MNG packet is an ARP response/request packet                                                                       |
| Pass MNG neighbor                     | 6     | Set when the MNG packet is a neighbor discovery packet.                                                                         |
| Pass MNG broadcast                    | 5     | Set when the MNG packet is a broadcast packet                                                                                   |
| Pass RMCP 0x0298                      | 4     | Set when the UDP/TCP port of the MNG packet is 0x298                                                                            |
| Pass RMCP 0x026F                      | 3     | Set when the UDP/TCP port of the MNG packet is 0x26F                                                                            |
| Manageability Ethertype filter passed | 2     | Indicates that one of the METF filters matched                                                                                  |
| manageability Ethertype filter index  | 1:0   | Indicates which of the METF filters matched                                                                                     |

### 10.5.10.2.2 Read Status Command

The BMC should use this command after receiving a notification from the I350 (such as SMBus Alert). The I350 also sends a notification to the BMC in either of the following two cases:

- The BMC asserts a request for reading the status.

- The I350 detects a change in one of the Status Data 1 bits (and was set to send status to the BMC on status change) in the Receive Enable command.

**Note:** Commands 0xC0/0xD0 are for backward compatibility and can be used for other payloads. The I350 defines these commands in the opcode as well as which payload this transaction is. When the 0XDE command is set, the I350 always returns opcode 0XDD with the I350 status. The BMC reads the event causing the notification, using the Read Status command as follows. The I350 response to one of the commands (0xC0 or 0xD0) in a given time as defined in the SMBus Notification Timeout and Flags word in the EEPROM.

| Function    | Command              |
|-------------|----------------------|
| Read Status | 0XC0 or 0XD0 or 0XDE |

| Function                   | Byte Count | Data 1<br>(Op-Code) | Data 2<br>(Status<br>Data 1) | Data 3<br>(Status Data 2) |
|----------------------------|------------|---------------------|------------------------------|---------------------------|
| Receive TCO Partial Status | 3          | 0XDD                | See Below                    |                           |

Table 10-21 lists the status data byte 1 parameters.

**Table 10-21 Status Data Byte 1**

| Bit          | Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                              |              |              |  |   |   |                              |   |   |                              |   |   |                              |   |   |                              |

1. This indication is asserted when the I350 manageability block reloads the EEPROM and its internal database is updated to the EEPROM default values. This is an indication that the external BMC should reconfigure the I350, if other values other than the EEPROM default should be configured.

Status data byte 2 is used by the BMC to indicate whether the LAN device driver is alive and running.

The LAN device driver valid indication is a bit set by the LAN device driver during initialization; the bit is cleared when the LAN device driver enters a Dx state or is cleared by the hardware on a PCI reset.

Bits 2 and 1 indicate that the LAN device driver is stuck. Bit 2 indicates whether the interrupt line of the LAN function is asserted. Bit 1 indicates whether the LAN device driver dealt with the interrupt line before the last Read Status cycle. [Table 10-22](#) lists status data byte 2.

**Table 10-22 Status Data Byte 2**

| Bit | Name                                      | Description                                                                                                                                                                                                                   |

| 2   | Interrupt Pending Indication              | 1b = LAN interrupt line is asserted.<br>0b = LAN interrupt line is not asserted.                                                                                                                                              |
| 1   | Interrupt Cause Register (ICR0 Read/Write | 1b = ICR register was read since the last read status cycle.<br>0b = ICR register was not read since the last read status cycle.<br>Reading the ICR indicates that the driver has dealt with the interrupt that was asserted. |
| 0   | Thermal Sensor event                      | 0b = No thermal event<br>1b = Thermal event asserted.                                                                                                                                                                         |

[Table 10-23](#) lists the possible values of bits 2 and 1 and what the BMC can assume from the bits:

**Table 10-23 Status Data Byte 2 (Bits 2 and 1)**

| Previous   | Current | Description                                                                                                         |
|------------|---------|---------------------------------------------------------------------------------------------------------------------|
| Don't Care | 00b     | Interrupt is not pending (OK).                                                                                      |
| 00b        | 01b     | New interrupt is asserted (OK).                                                                                     |
| 10b        | 01b     | New interrupt is asserted (OK).                                                                                     |
| 11b        | 01b     | Interrupt is waiting for reading (OK).                                                                              |
| 01b        | 01b     | Interrupt is waiting for reading by the driver for more than one read cycle (not OK).<br>Possible drive hang state. |
| Don't Care | 11b     | Previous interrupt was read and current interrupt is pending (OK).                                                  |
| Don't Care | 10b     | Interrupt is not pending (OK).                                                                                      |

BMC reads should consider the time it takes for the LAN device driver to deal with the interrupt (in  $\mu$ s). Note that excessive reads by the BMC can give false indications.

### 10.5.10.2.3 Get System MAC Address Command

The Get System MAC Address returns the system MAC address over to the SMBus. This command is a single-fragment Read Block transaction that returns the following the MAC address configured in RAL0, RAH0 registers.

Get system MAC address format:

| Function               | Command |
|------------------------|---------|
| Get system MAC address | 0xD4    |

Data returned from the I350:

| Function               | Byte Count | Data 1 (Op-Code) | Data 2          | ... | Data 7          |
|------------------------|------------|------------------|-----------------|-----|-----------------|
| Get system MAC address | 7          | 0xD4             | MAC address MSB | ... | MAC address LSB |

#### 10.5.10.2.4 Read Management Parameters Command

In order to read the management parameters the BMC should execute two SMBus transactions. The first transaction is a block write that sets the parameter that the BMC wants to read. The second transaction is block read that reads the parameter.

Block write transaction:

| Function                   | Command | Byte Count | Data 1           |
|----------------------------|---------|------------|------------------|
| Management control request | 0xC1    | 1          | Parameter number |

Following the block write the BMC should issue a block read that reads the parameter that was set in the Block Write command:

| Function                  | Command |
|---------------------------|---------|
| Read management parameter | 0xD1    |

Data returned:

| Function                  | Byte Count | Data 1 (Op-Code) | Data 2           | Data 3              | ... | Data N |
|---------------------------|------------|------------------|------------------|---------------------|-----|--------|
| Read management parameter | N          | 0xD1             | Parameter number | Parameter dependent |     |        |

The returned data is in the same format of the BMC command. The returned data is as follow:

| Parameter               | #    | Parameter Data                                                                                                                                                                                                                                                                                          |
|-------------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Keep PHY Link Up        | 0x00 | A single byte parameter:<br>Data 2 —<br>Bit 0 Set to indicate that the PHY link for this port should be kept up. Sets the keep_PHY_link_up bit. When cleared, clears the keep_PHY_link_up bit.<br>Bit [7:1] Reserved.                                                                                   |
| Wrong parameter request | 0xFE | Returned by the I350 only. This parameter is returned on read transaction, if in the previous read command the BMC sets a parameter that is not supported by the I350.                                                                                                                                  |
| The I350 is not ready   | 0xFF | Returned by the I350 only, on read parameters command when the data that should have been read is not ready. This parameter has no data. The BMC should retry the read transaction. This value is also returned if the byte count is illegal or if the read command is not preceded by a write command. |

The parameter that is returned might not be the parameter requested by the BMC. The BMC should verify the parameter number (default parameter to be returned is 0x1).

If the parameter number is 0xFF, it means that the data that was requested from the I350 is not ready yet. The BMC should retry the read transaction.

It is responsibility of the BMC to follow the procedure previously defined. When the BMC sends a Block Read command (as previously described) that is not preceded by a Block Write command with bytecount=1, the I350 sets the parameter number in the read block transaction to be 0xFF.

#### 10.5.10.2.5 Read Management Receive Filter Parameters Command

In order to read the management receive filter parameters, the BMC should execute two SMBus transactions. The first transaction is a block write that sets the parameter that the BMC wants to read. The second transaction is block read that read the parameter.

Block write transaction:

| Function                         | Command | Byte Count | Data 1           | Data 2         |
|----------------------------------|---------|------------|------------------|----------------|
| Update MNG RCV filter parameters | 0xCC    | 1 or 2     | Parameter number | Parameter data |

The different parameters supported for this command are the same as the parameters supported for update Management receive filter parameters.

Following the block write the BMC should issue a block read that reads the parameter that was set in the Block Write command:

| Function                          | Command |
|-----------------------------------|---------|
| Request MNG RCV filter parameters | 0xCD    |

Data returned from the I350:

| Function                       | Byte Count | Data 1 (Op-Code) | Data 2           | Data 3              | ... | Data N |
|--------------------------------|------------|------------------|------------------|---------------------|-----|--------|
| Read MNG RCV filter parameters | N          | 0xCD             | Parameter number | Parameter dependent |     |        |

The parameter that is returned might not be the parameter requested by the BMC. The BMC should verify the parameter number (default parameter to be returned is 0x1).

If the parameter number is 0xFF, it means that the data that was requested from the I350 should supply is not ready yet. The BMC should retry the read transaction.

It is BMC responsibility to follow the procedure previously defined. When the BMC sends a Block Read command (as previously described) that is not preceded by a Block Write command with bytecount=1 or 2, the I350 sets the parameter number in the read block transaction to be 0xFF.

| Parameter                          | #    | Parameter Data                                                                                                                                                                                                                                                  |
|------------------------------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filters Enable                     | 0x01 | None                                                                                                                                                                                                                                                            |
| MNGONLY Configuration              | 0x0F | None                                                                                                                                                                                                                                                            |
| Flex Filter Enable Mask and Length | 0x10 | None                                                                                                                                                                                                                                                            |

| IPv6 Filters                       | 0x65 | One byte to define the accessed IPv6 address filter (MIPAF)<br>Data 2 — Pv6 address filter number                                                                                                                                                               |
| MAC Filters                        | 0x66 | One byte to define the accessed MAC address filters pair (MMAL, MMAH)<br>Data 2 — MAC address filters pair number (0 - 3)                                                                                                                                       |
| EtherType Filters                  | 0x67 | 1 byte to define Ethertype filters (METF)<br>Data 2 — METF filter index (valid values are 0 - 3)                                                                                                                                                                |
| Extended Decision Filter           | 0x68 | 1 byte to define the extended decisions filters (MDEF_EXT & MDEF)<br>Data 2 — MDEF filter index (valid values are 0 - 6)                                                                                                                                        |
| Wrong parameter request            | 0xFE | Returned by the I350 only. This parameter is returned on read transaction, if in the previous read command the BMC sets a parameter that is not supported by the I350.                                                                                          |
| The I350 is not ready              | 0xFF | Returned by the I350 only, on read parameters command when the data that should have been read is not ready. This parameter has no data.<br>This value is also returned if the byte count is illegal or if the read command is not preceded by a write command. |

#### 10.5.10.2.6 Read Receive Enable Configuration Command

The BMC uses this command to read the receive configuration data. This data can be configured when using Receive Enable command or through the EEPROM.

Read Receive Enable Configuration command format (SMBus Read Block) is as follows:

| Function            | Command |
|---------------------|---------|
| Read Receive Enable | 0xDA    |

Data returned from the I350:

| Function | Byte Count | Data 1 (Op-Code) | Data 2 | Data 3 | ... | Data 8 | Data 9 | ... | Data 12 | Data 13 | Data 14 | Data 15 |
|----------|------------|------------------|--------|--------|-----|--------|--------|-----|---------|---------|---------|---------|
|----------|------------|------------------|--------|--------|-----|--------|--------|-----|---------|---------|---------|---------|

|                     |           |      |                      |              |     |              |             |     |             |                |               |                  |
|---------------------|-----------|------|----------------------|--------------|-----|--------------|-------------|-----|-------------|----------------|---------------|------------------|
| Read Receive Enable | 15 (0x0F) | 0xDA | Receive Control Byte | MAC Addr MSB | ... | MAC Addr LSB | IP Addr MSB | ... | IP Addr LSB | BMC SMBus Addr | I/F Data Byte | Alert Value Byte |
|---------------------|-----------|------|----------------------|--------------|-----|--------------|-------------|-----|-------------|----------------|---------------|------------------|

The detailed description of each field is specified in the receive enable command description in [Section 10.5.10.1.3](#).

### 10.5.10.2.7 Get Thermal Sensor Capabilities Command

The BMC can use this function to read the thermal sensor capabilities. It uses a write command to set the needed index and then a read block command to read the data.

The write command is

| Function                         | Command | Byte Count | Data 1 |
|----------------------------------|---------|------------|--------|
| Get Thermal Capabilities Request | 0xCB    | 1          | 0x0    |

The read command is:

| Function                         | Command |
|----------------------------------|---------|
| Get Thermal Capabilities Request | 0xDB    |

Data returned from the I350 is

| Function                        | Byte Count | Data 1 (Op-Code) | Data 2 (index) | Data 3 (Version) | Data 4 (Unit Types)             | Data 5-6 (Number of Thresholds) |
|---------------------------------|------------|------------------|----------------|------------------|---------------------------------|---------------------------------|
| Get Thermal Sensor capabilities | 24         | 0xDB             | 0x0x           | 1                | See <a href="#">Table 10-45</a> | See below                       |

| Data 7 (Accuracy) | Data 8 (Hysteresis) | Data 9 (M) | Data 10 (B) | Data 11 (K1) | Data 12 (K2) | Data 13-16 (Valid High going Actions) | Data 17-20 (Valid Low going Actions) | Data 21-24 (Valid Immediate Actions) | Data 25-26 (TJunction Max) |
|-------------------|---------------------|------------|-------------|--------------|--------------|---------------------------------------|--------------------------------------|--------------------------------------|----------------------------|
|                   | See Below           | See below  |             |              |              | See <a href="#">Table 10-44</a>       | See <a href="#">Table 10-44</a>      | See <a href="#">Table 10-44</a>      | See below                  |

- Version should always be 1.
- Unit Types describes the unit types measured according to the encoding in [Table 10-45](#).
- Accuracy describes the accuracy of the reported measurements as follow:
  - 7:4: Max deviation of actual value above measurement in “unit types”.
  - 3:0: Max deviation of actual value below measurement in “unit types”.
- Max hysteresis - defines the max hysteresis value allowed in the implementation. A value of zero means hysteresis is not supported.
- Number of thresholds describes the number of up and down thresholds as follow:
  - 15:12: Reserved

- 11:8: Max Number of mixed thresholds.
- 7:4: Max number of up thresholds.
- 3:0: Max number of down thresholds.
- Valid Actions “High going” thresholds - describes the actions that can be activated by the device as described in Table 10-44 when an high going threshold is crossed or the upper hysteresis of a “Low Going” Threshold is crossed.
- Valid Actions “Low going” thresholds - describes the actions that can be activated by the device as described in Table 10-44 when an low going threshold is crossed or the lower hysteresis of a “Low Going” Threshold is crossed.
- Valid Actions “Immediate” - describes the actions that can be activated by the device as described in Table 10-44 using a “Perform Thermal Sensor Action” command.
- M, B, K1, K2 - parameters used to translate the raw data read to a meaningful value according to the following formula:

$$Y = (MX + (B * 10^{K1})) * 10^{K2}$$

where X is the measured value and Y is the value presented to the user.

**Note:** This formula is compliant with the definition of section 36.3 “Sensor Reading Conversion Formula” in IPMI 2.0

- Tjunction Max - The maximal junction temperature supported (125 C)

#### 10.5.10.2.8 Get Thermal Sensor Configuration Command

The BMC can use this function to read the thermal sensor configuration for a given threshold. It uses a write command to set the needed index and then a read block command to read the data.

The write command is

| Function                          | Command | Byte Count | Data 1 | Data 1 |
|-----------------------------------|---------|------------|--------|--------|
| Get Thermal configuration Request | 0xCB    | 2          | 0x1    | Index  |

The read command is

| Function                         | Byte Count | Data 1 (Op-Code) | Data 2 (command) | Data 3 (index) | Data 4-5 (Threshold)     |
|----------------------------------|------------|------------------|------------------|----------------|--------------------------|
| Get Thermal Sensor configuration | 15         | 0xDB             | 0x1              | index          | The programmed threshold |

| Data 6-9 (Action “Going High”)                     | Data 10-13 (Action “Going Low”)                    | Data 14 (Direction) | Data 15 (Hysteresis) |
|----------------------------------------------------|----------------------------------------------------|---------------------|----------------------|
| The programmed actions as described in Table 10-44 | The programmed actions as described in Table 10-44 | See below           | See below            |

The threshold and the Hysteresis are measured in “unit types”.

The “Actions Going High” field describes the actions to activate upon crossing of the threshold for “Going High” thresholds or when crossing the hysteresis for “Going Low” thresholds according to [Table 10-44](#).

The “Actions Going Low” field describes the actions to activate upon crossing of the threshold for “Going Low” thresholds or when crossing the hysteresis for “Going High” thresholds according to [Table 10-44](#).

Direction is encoded as follow:

- 0 = High Going
- 1 = Low Going

#### 10.5.10.2.9 Get Thermal Sensor Status Command

The BMC can use this function to read the thermal sensor status. It uses a write command to set the needed index and then a read block command to read the data.

The write command is

| Function                          | Command | Byte Count | Index |
|-----------------------------------|---------|------------|-------|
| Get Thermal Sensor Status Request | 0xCB    | 1          | 0x2   |

The read command is

| Function                  | Byte Count | Data 1 (Op-Code) | Data 2 (command) | Data 3-4 (Measured Value)          | Data 5-8 (Active Actions)                                                | Data 9-10 (Threshold cross event) |
|---------------------------|------------|------------------|------------------|------------------------------------|--------------------------------------------------------------------------|-----------------------------------|
| Get Thermal Sensor Status | 10         | 0xDB             | 0x2              | The value measured in “unit types” | The currently active actions as described in <a href="#">Table 10-44</a> | See below                         |

“Threshold cross events” is a bitmap that describes which events were crossed since the last read of the status or since the activation of the thermal sensor (the latest of the two).

### 10.5.11 Example Configuration Steps

This section provides sample configuration settings for common filtering configurations. Three examples are presented. The examples are in pseudo code format, with the name of the SMBus command followed by the parameters for that command and an explanation.

#### 10.5.11.1 Example 1 - Shared MAC, RMCP Only Ports

This example is the most basic configuration. The MAC address filtering is shared with the Host operating system and only traffic directed the RMCP ports (26Fh & 298h) is filtered. For this example, the BMC must issue gratuitous ARPs because no filter is enabled to pass ARP requests to the BMC.

##### 10.5.11.1.1 Example 1 Pseudo Code

Step 1: Disable existing filtering

### Receive Enable[00]

Utilizing the simple form of the Receive Enable command, this prevents any packets from reaching the BMC by disabling filtering:

Receive Enable Control 00h:

- Bit 0 [0] – Disable Receiving of packets

Step 2: Configure MDEF[0]

### Update Manageability Filter Parameters [61, 0, C0000000]

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 61h). This will update MDEF[0], as indicated by the 2nd parameter (0).

MDEF[0] value of C0000000h:

- Bit 30 [1] – port 298h
- Bit 31 [1] – port 26Fh

Step 3: Configure MNGONLY

### Update Manageability Filter Parameters [F, 0, 00000001]

Use the Update Manageability Filter Parameters command to update Manageability Only (MNGONLY) (parameter Fh) so that port 298h and 26Fh would not be sent to the Host.

- Bit [0] - MDEF[0] is exclusive to the BMC.

Step 4: - Enable Filtering

### Receive Enable [05]

Using the simple form of the Receive Enable command:

Receive Enable Control 05h:

- Bit 0 [1] – Enable Receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)
- Bit 5:4 [00] – Notification method = SMB Alert
- Bit 7 [0] – Use shared MAC

The resulting MDEF filters are as follows:

**Table 10-25 Example 1 MDEF Results**

|                         |     | Manageability Decision Filter (MDEF) |   |   |   |   |   |   |   |
|-------------------------|-----|--------------------------------------|---|---|---|---|---|---|---|
| Filter                  |     | 0                                    | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| L2 Exact Address[3:0]   | AND |                                      |   |   |   |   |   |   |   |
| Broadcast               | AND |                                      |   |   |   |   |   |   |   |
| Manageability VLAN[7:0] | AND |                                      |   |   |   |   |   |   |   |
| IPv6 Address[3:0]       | AND |                                      |   |   |   |   |   |   |   |
| IPv4 Address[3:0]       | AND |                                      |   |   |   |   |   |   |   |
| L2 Exact Address[3:0]   | OR  |                                      |   |   |   |   |   |   |   |
| Broadcast               | OR  |                                      |   |   |   |   |   |   |   |
| Multicast               | AND |                                      |   |   |   |   |   |   |   |

**Table 10-25 Example 1 MDEF Results**

|                    |    |   |  |  |  |  |  |  |  |
|--------------------|----|---|--|--|--|--|--|--|--|
| ARP Request        | OR |   |  |  |  |  |  |  |  |
| ARP Response       | OR |   |  |  |  |  |  |  |  |
| Neighbor Discovery | OR |   |  |  |  |  |  |  |  |
| Port 0x298         | OR | X |  |  |  |  |  |  |  |
| Port 0x26F         | OR | X |  |  |  |  |  |  |  |
| Flex Port 7:0      | OR |   |  |  |  |  |  |  |  |
| Flex TCO           | OR |   |  |  |  |  |  |  |  |

### 10.5.11.2 Example 2 - Dedicated MAC, Auto ARP Response and RMCP Port Filtering

This example shows a common configuration; the BMC has a dedicated MAC and IP address. Automatic ARP responses will be enabled as well as RMCP port filtering. By enabling Automatic ARP responses the BMC is not required to send the gratuitous ARPs as it did in Example 1.

For demonstration purposes, the dedicated MAC address will be calculated by reading the System MAC address and adding 1 to it, assume the System MAC is AABBCDC. The IP address for this example will be 1.2.3.4. Additionally, the XSUM filtering will be enabled.

Note that not all Intel Ethernet Controllers support automatic ARP responses, please refer to product specific documentation.

#### 10.5.11.2.1 Example 2 - Pseudo Code

Step 1: Disable existing filtering

##### Receive Enable[00]

Utilizing the simple form of the Receive Enable command, this prevents any packets from reaching the BMC by disabling filtering:

Receive Enable Control 00h:

- Bit 0 [0] – Disable Receiving of packets

Step 2: Read System MAC Address

##### Get System MAC Address []

Reads the System MAC address. Assume returned AABBCDC for this example.

Step 3: Configure XSUM Filter

##### Update Manageability Filter Parameters [01, 00800000]

Use the Update Manageability Filter Parameters command to update Filters Enable settings (parameter 1). This sets the Manageability Control (MANC) Register.

MANC Register 00800000h:

- Bit 23 [1] - XSUM Filter enable

Note that some of the following configuration steps manipulate the MANC register indirectly, this command sets all bits except XSUM to 0. It is important to either do this step before the others, or to read the value of the MANC and then write it back with only bit 32 changed. Also note that the XSUM enable bit may differ between Ethernet Controllers, refer to product specific documentation.

Step 4: Configure MDEF[0]

**Update Manageability Filter Parameters [61, 0, C0000000]**

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 61h). This will update MDEF[0], as indicated by the 2nd parameter (0).

MDEF value of 00000C00h:

- Bit 30 [1] – port 298h
- Bit 31 [1] – port 26Fh

Step 5: Configure MDEF[1]

**Update Manageability Filter Parameters [61, 1, 10000000]**

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 61h). This will update MDEF[1], as indicated by the 2<sup>nd</sup> parameter (1).

MDEF value of 10000000:

- Bit 28 [1] – ARP Requests

When Enabling Automatic ARP responses, the ARP requests still go into the manageability filtering system and as such need to be designated as also needing to be sent to the Host. For this reason a separate MDEF is created with only ARP request filtering enabled.

Refer to the next step for more details.

Step 6: Configure Manageability only

**Update Manageability Filter Parameters [F, 0, 00000001]**

Use the Update Manageability Filter Parameters command to update Manageability Only (MNGONLY) (parameter Fh) so that port 298h and 26Fh would not be sent to the Host.

- Bit [0] - MDEF[0] is exclusive to the BMC.

This allows ARP requests to be passed to both manageability and to the Host. Specified separate MDEF filter for ARP requests. If ARP requests had been added to *MDEF[0]* and then *MDEF[0]* specified in Management Only configuration then not only would RMCP traffic (ports 26Fh and 298h) be sent only to the BMC, ARP requests would have also been sent to the BMC only.

Step 7: Enable Filtering

**Receive Enable [8D, AABBCDD, 01020304, 00, 00, 00]**

Using the advanced version Receive Enable command, the first parameter:

Receive Enable Control 8Dh:

- Bit 0 [1] – Enable Receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)
- Bit 3 [1] – Enable Automatic ARP Responses
- Bit 5:4 [00] – Notification method = SMB Alert
- Bit 7 [1] - Use dedicated MAC

Second parameter is the MAC address (AABBCDD).

Third Parameter is the IP address(01020304).

The last three parameters are zero when the notification method is SMB Alert.

The resulting MDEF filters are as follows:

**Table 10-26 Example 2 MDEF Results**

|                         |     | Manageability Decision Filter (MDEF) |   |   |   |   |   |   |   |
|-------------------------|-----|--------------------------------------|---|---|---|---|---|---|---|
| Filter                  |     | 0                                    | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| L2 Exact Address[3:0]   | AND |                                      |   |   |   |   |   |   |   |
| Broadcast               | AND |                                      |   |   |   |   |   |   |   |
| Manageability VLAN[7:0] | AND |                                      |   |   |   |   |   |   |   |
| IPv6 Address[3:0]       | AND |                                      |   |   |   |   |   |   |   |
| IPv4 Address[3:0]       | AND |                                      |   |   |   |   |   |   |   |
| L2 Exact Address[3:0]   | OR  |                                      |   |   |   |   |   |   |   |
| Broadcast               | OR  |                                      |   |   |   |   |   |   |   |
| Multicast               | AND |                                      |   |   |   |   |   |   |   |
| ARP Request             | OR  |                                      | X |   |   |   |   |   |   |
| ARP Response            | OR  |                                      |   |   |   |   |   |   |   |
| Neighbor Discovery      | OR  |                                      |   |   |   |   |   |   |   |
| Port 0x298              | OR  | X                                    |   |   |   |   |   |   |   |
| Port 0x26F              | OR  | X                                    |   |   |   |   |   |   |   |
| Flex Port 7:0           | OR  |                                      |   |   |   |   |   |   |   |
| Flex TCO                | OR  |                                      |   |   |   |   |   |   |   |

### 10.5.11.3 Example 3 - Dedicated MAC & IP Address

This example provided the BMC with a dedicated MAC and IP address and allows it to receive ARP requests. The BMC is then responsible for responding to ARP requests.

For demonstration purposes, the dedicated MAC address will be calculated by reading the System MAC address and adding 1 to it, assume the System MAC is AABBCDC. The IP address for this example will be 1.2.3.4. For this example, the Receive Enable command is used to configure the MAC address filter.

In order for the BMC to be able to receive ARP Requests, it will need to specify a filter for this, and that filter will need to be included in the Manageability To Host filtering so that the Host OS may also receive ARP Requests.

#### 10.5.11.3.1 Example 3 - Pseudo Code

Step 1: Disable existing filtering

##### Receive Enable[00]

Utilizing the simple form of the Receive Enable command, this prevents any packets from reaching the BMC by disabling filtering:

Receive Enable Control 00h:

- Bit 0 [0] – Disable Receiving of packets

Step 2: Read System MAC Address

##### Get System MAC Address []

Reads the System MAC address. Assume returned AABBCDC for this example.

Step 3: Configure IP Address Filter

**Update Manageability Filter Parameters [64, 00, 01020304]**

Use the Update Manageability Filter Parameters to configure an IPv4 filter.

The 1st parameter (64h) specifies that we are configuring an IPv4 filter.

The 2nd parameter (00h) indicates which IPv4 filter is being configured, in this case filter 0.

The 3rd parameter is the IP address – 1.2.3.4.

Step 4: Configure MAC Address Filter

**Update Manageability Filter Parameters [66, 00, AABBCDD]**

Use the Update Manageability Filter Parameters to configure a MAC Address filter.

The 1st parameter (66h) specifies that we are configuring a MAC Address filter.

The 2nd parameter (00h) indicates which MAC Address filter is being configured, in this case filter 0.

The 3rd parameter is the MAC Address - AABBCDD

Step 5: Configure *MDEF[0]* for IP and MAC Filtering

**Update Manageability Filter Parameters [61, 0, 00002001]**

Use the Update Manageability Filter Parameters command to update Decision Filters (*MDEF*) (parameter 61h). This will update *MDEF[0]*, as indicated by the 2nd parameter (0).

*MDEF* value of 00002001:

- Bit 0 [1] – MAC[0] Address Filtering
- Bit 13 [1] – IP[0] Address Filtering

Step 6: Configure *MDEF[1]*

**Update Manageability Filter Parameters [61, 1, 10000000]**

Use the Update Manageability Filter Parameters command to update Decision Filters (*MDEF*) (parameter 61h). This will update *MDEF[1]*, as indicated by the 2nd parameter (1).

*MDEF* value of 10000000:

- Bit 28 [1] – ARP Requests

Step 7: Configure the Management to Host Filter

**Update Manageability Filter Parameters [F, 0, 00000001]**

Use the Update Manageability Filter Parameters command to update Manageability Only (*MNGONLY*) (parameter Fh) so that the dedicated MAC/IP traffic would not be sent to the Host. Note that given the Host will not program this address in its L2 filtering, this step is not a must, unless the Host chooses to work in promiscuous mode.

- Bit [0] - *MDEF[0]* is exclusive to the BMC.

Step 8: Enable Filtering

**Receive Enable [05]**

Using the simple form of the Receive Enable command,:

Receive Enable Control 05h:

- Bit 0 [1] – Enable Receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)
- Bit 5:4 [00] – Notification method = SMB Alert

The resulting MDEF filters are as follows:

**Table 10-27 Example 3 MDEF Results**

|                         |     | Manageability Decision Filter (MDEF) |   |   |   |   |   |   |   |
|-------------------------|-----|--------------------------------------|---|---|---|---|---|---|---|
| Filter                  |     | 0                                    | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| L2 Exact Address[3:0]   | AND | 0001                                 |   |   |   |   |   |   |   |
| Broadcast               | AND |                                      |   |   |   |   |   |   |   |
| Manageability VLAN[7:0] | AND |                                      |   |   |   |   |   |   |   |
| IPv6 Address[3:0]       | AND |                                      |   |   |   |   |   |   |   |
| IPv4 Address[3:0]       | AND | 0001                                 |   |   |   |   |   |   |   |
| L2 Exact Address[3:0]   | OR  |                                      |   |   |   |   |   |   |   |
| Broadcast               | OR  |                                      |   |   |   |   |   |   |   |
| Multicast               | AND |                                      |   |   |   |   |   |   |   |
| ARP Request             | OR  |                                      | X |   |   |   |   |   |   |
| ARP Response            | OR  |                                      |   |   |   |   |   |   |   |
| Neighbor Discovery      | OR  |                                      |   |   |   |   |   |   |   |
| Port 0x298              | OR  |                                      |   |   |   |   |   |   |   |
| Port 0x26F              | OR  |                                      |   |   |   |   |   |   |   |
| Flex Port 7:0           | OR  |                                      |   |   |   |   |   |   |   |
| Flex TCO                | OR  |                                      |   |   |   |   |   |   |   |

#### 10.5.11.4 Example 4 - Dedicated MAC and VLAN Tag

This example shows an alternate configuration; the BMC has a dedicated MAC and IP address, along with a VLAN tag of 32h will be required for traffic to be sent to the BMC. This means that all traffic with VLAN a matching tag will be sent to the BMC.

For demonstration purposes, the dedicated MAC address will be calculated by reading the System MAC address and adding 1 to it, assume the System MAC is AABBCDC. The IP address for this example will be 1.2.3.4 and the VLAN tag will be 0032h.

Additionally, the XSUM filtering will be enabled.

##### 10.5.11.4.1 Example 4 - Pseudo Code

Step 1: Disable existing filtering

##### Receive Enable[00]

Utilizing the simple form of the Receive Enable command, this prevents any packets from reaching the BMC by disabling filtering:

Receive Enable Control 00h:

- Bit 0 [0] – Disable Receiving of packets

Step 2: - Read System MAC Address

## Get System MAC Address []

Reads the System MAC address. Assume returned AABBCDC for this example.

### Step 3: Configure XSUM Filter

#### Update Manageability Filter Parameters [01, 00800000]

Use the Update Manageability Filter Parameters command to update Filters Enable settings (parameter 1). This set the Manageability Control (MANC) Register.

MANC Register 00800000h:

- Bit 23 [1] – XSUM Filter enable

Note that some of the following configuration steps manipulate the MANC register indirectly, this command sets all bits except XSUM to 0. It is important to either do this step before the others, or to read the value of the MANC and then write it back with only bit 32 changed. Also note that the XSUM enable bit may differ between Ethernet Controllers, refer to product specific documentation.

### Step 4: Configure VLAN 0 Filter

#### Update Manageability Filter Parameters [62, 0, 0032]

Use the Update Manageability Filter Parameters command to configure VLAN filters. Parameter 62h indicates update to VLAN Filter, the 2nd parameter indicates which VLAN filter (0 in this case), the last parameter is the VLAN ID (0032h).

### Step 5: Configure MDEF[0]

#### Update Manageability Filter Parameters [61, 0, 00000020]

Use the Update Manageability Filter Parameters command to update Decision Filters (MDEF) (parameter 61h). This will update MDEF[0], as indicated by the 2nd parameter (0).

MDEF value of 00000020:

- Bit 5 [1] – VLAN[0] AND

### Step 6: Enable Filtering

#### Receive Enable [85, AABCCDD, 01020304, 00, 00, 00]

Using the advanced version Receive Enable command, the first parameter:

Receive Enable Control 85h:

- Bit 0 [1] – Enable Receiving of packets
- Bit 2 [1] – Enable status reporting (such as link lost)
- Bit 5:4 [00] – Notification method = SMB Alert
- Bit 7 [1] – Use Dedicated MAC

Second parameter is the MAC address: AABCCDD.

Third Parameter is the IP address: 01020304.

The last three parameters are zero when the notification method is SMBus Alert.

The resulting MDEF filters are as follows:

**Table 10-28 Example 4 MDEF Results**

|                         |     | Manageability Decision Filter (MDEF) |   |   |   |   |   |   |      |
|-------------------------|-----|--------------------------------------|---|---|---|---|---|---|------|
| Filter                  |     | 0                                    | 1 | 2 | 3 | 4 | 5 | 6 | 7    |
| L2 Exact Address[3:0]   | AND |                                      |   |   |   |   |   |   | 0001 |
| Broadcast               | AND |                                      |   |   |   |   |   |   |      |
| Manageability VLAN[7:0] | AND | X                                    |   |   |   |   |   |   |      |
| IPv6 Address[3:0]       | AND |                                      |   |   |   |   |   |   |      |
| IPv4 Address[3:0]       | AND |                                      |   |   |   |   |   |   |      |
| L2 Exact Address[3:0]   | OR  |                                      |   |   |   |   |   |   |      |
| Broadcast               | OR  |                                      |   |   |   |   |   |   |      |
| Multicast               | AND |                                      |   |   |   |   |   |   |      |
| ARP Request             | OR  |                                      |   |   |   |   |   |   |      |
| ARP Response            | OR  |                                      |   |   |   |   |   |   |      |
| Neighbor Discovery      | OR  |                                      |   |   |   |   |   |   |      |
| Port 0x298              | OR  |                                      |   |   |   |   |   |   |      |
| Port 0x26F              | OR  |                                      |   |   |   |   |   |   |      |
| Flex Port 7:0           | OR  |                                      |   |   |   |   |   |   |      |
| Flex TCO                | OR  |                                      |   |   |   |   |   |   |      |

## 10.5.12 SMBus Troubleshooting

This section outlines the most common issues found while working with pass-through using the SMBus sideband interface.

### 10.5.12.1 TCO Alert Line Stays Asserted After a Power Cycle

After the I350 resets, all its ports indicate a status change. If the BMC only reads status from one port (slave address), the other ports will continue to assert the TCO alert line.

Ideally, the BMC should use the ARA transaction (see [Section 10.5.9](#)) to determine which slave asserted the TCO alert. Many customers only wish to use one port for manageability thus using ARA might not be optimal.

An alternate to using ARA is to configure one of the ports to not report status and to set its SMBus timeout period. In this case, the SMBus timeout period determines how long a port asserts the TCO alert line awaiting a status read from a BMC; by default this value is zero (indicates an infinite timeout).

The SMBus configuration section of the EEPROM has a SMBus Notification Timeout (ms) field that can be set to a recommended value of 0xFF (for this issue). Note that this timeout value is for all slave addresses. Along with setting the SMBus Notification Timeout to 0xFF, it is recommended that the other ports be configured in the EEPROM to disable status alerting. This is accomplished by having the *Enable Status Reporting* bit set to 0b for the desired port in the LAN configuration section of the EEPROM.

The third solution for this issue is to have the BMC hard-code the slave addresses to always read from all ports. As with the previous solution, it is recommended that the other ports have status reporting disabled.

### 10.5.12.2 When SMBus Commands Are Always NACK'd

There are several reasons why all commands sent to the I350 from a BMC could be NACK'd. The following are most common:

- Invalid EEPROM Image — The image itself might be invalid or it could be a valid image and is not a pass-through image, as such SMBus connectivity is disabled.
- The BMC is not using the correct SMBus address — Many BMC vendors hard-code the SMBus address(es) into their firmware. If the incorrect values are hard-coded, the I350 does not respond.
  - The SMBus address(es) can be dynamically set using the SMBus ARP mechanism.
- The BMC is using the incorrect SMBus interface — The EEPROM might be configured to use one physical SMBus port; however, the BMC is physically connected to a different one.
- Bus Interference — the bus connecting the BMC and the I350 might be unstable.

### 10.5.12.3 SMBus Clock Speed Is 16.6666 KHz

This can happen when the SMBus connecting the BMC and the I350 is also tied into another device (such as an ICH) that has a maximum clock speed of 16.6666 KHz. The solution is to not connect the SMBus between the I350 and the BMC to this device.

### 10.5.12.4 A Network Based Host Application Is Not Receiving Any Network Packets

Reports have been received about an application not receiving any network packets. The application in question was NFS under Linux. The problem was that the application was using the RMPC/RMCP+ IANA reserved port 0x26F (623) and the system was also configured for a shared MAC and IP address with the OS and BMC.

The management control to Host configuration, in this situation, was setup not to send RMCP traffic to the OS (this is typically the correct configuration). This means that no traffic sent to port 623 was being routed.

The solution in this case is to configure the problematic application NOT to use the reserved port 0x26F.

### 10.5.12.5 Unable to Transmit Packets from the BMC

If the BMC has been transmitting and receiving data without issue for a period of time and then begins to receive NACKs from the I350 when it attempts to write a packet, the problem is most likely due to the fact that the buffers internal to the I350 are full of data that has been received from the network but has yet to be read by the BMC.

Being an embedded device, the I350 has limited buffers that are shared for receiving and transmitting data. If a BMC does not keep the incoming data read, the I350 can be filled up. This prevents the BMC from transmitting more data, resulting in NACKs.

If this situation occurs, the recommended solution is to have the BMC issue a Receive Enable command to disable more incoming data, read all the data from the I350, and then use the Receive Enable command to enable incoming data.

### 10.5.12.6 SMBus Fragment Size

The SMBus specification indicates a maximum SMBus transaction size of 32 bytes. Most of the data passed between the I350 and the BMC over the SMBus is RMCP/RMCP+ traffic, which by its very nature (UDP traffic) is significantly larger than 32 bytes in length. Multiple SMBus transactions may therefore be required to move data from the I350 to the BMC or to send a data from the BMC to the I350.

Recognizing this bottleneck, the I350 handles up to 240 bytes of data in a single transaction. This is a configurable setting in the EEPROM. The default value in the EEPROM images is 32, per the SMBus specification. If performance is an issue, increase this size.

During initialization, firmware within the I350 allocates buffers based upon the SMBus fragment size setting within the EEPROM. The I350 firmware has a finite amount of RAM for its use: the larger the SMBus fragment size, the fewer buffers it can allocate. Because this is true, BMC implementations must take care to send data over the SMBus efficiently.

For example, the I350 firmware has 3 KB of RAM it can use for buffering SMBus fragments. If the SMBus fragment size is 32 bytes then the firmware could allocate 96 buffers of size 32 bytes each. As a result, the BMC could then send a large packet of data (such as KVM) that is 800 bytes in size in 25 fragments of size 32 bytes apiece.

However, this might not be the most efficient way because the BMC must break the 800 bytes of data into 25 fragments and send each one at a time.

If the SMBus fragment size is changed to 240 bytes, the I350 firmware can create 12 buffers of 240 bytes each to receive SMBus fragments. The BMC can now send that same 800 bytes of KVM data in only four fragments, which is much more efficient.

The problem of changing the SMBus fragment size in the EEPROM is if the BMC does not also reflect this change. If a programmer changes the SMBus fragment size in the I350 to 240 bytes and then wants to send 800 bytes of KVM data, the BMC can still only send the data in 32 byte fragments. As a result, firmware runs out of memory.

This is because firmware created the 12 buffers of 240 bytes each for fragments; however, the BMC is only sending fragments of size 32 bytes. This results in a memory waste of 208 bytes per fragment. Then when the BMC attempts to send more than 12 fragments in a single transaction, the I350 NACKs the SMBus transaction due to not enough memory to store the KVM data.

In summary, if a programmer increases the size of the SMBus fragment size in the EEPROM (recommended for efficiency purposes) take care to ensure that the BMC implementation reflects this change and uses that fragment size to its fullest when sending SMBus fragments.

### 10.5.12.7 Losing Link

Normal behavior for the Ethernet Controller when the system powers down or performs a reset is for the link to temporarily go down and then back up again to re-negotiate the link speed. This behavior can have adverse affects on manageability.

For example if there is an active FTP or Serial Over LAN session to the BMC, this connection may be lost. In order to avoid this possible situation, the BMC can use the Management Control command detailed in [Section 10.5.10.1.5](#) to ensure the link stays active at all times.

This command is available when using the NC-SI sideband interface as well.

Care should be taken with this command, if the driver negotiates the maximum link speed, the link speed will remain the same when the system powers down or resets. This may have undesirable power consumption consequences. Currently, when using NC-SI, the BMC can re-negotiate the link speed. That functionality is not available when using the SMBus interface.

### 10.5.12.8 Enable XSum Filtering

If XSum filtering is enabled, the BMC does not need to perform the task of checking this checksum for incoming packets. Only packets that have a valid XSum is passed to the BMC. All others are silently discarded.

This is a way to offload some work from the BMC.

### 10.5.12.9 Still Having Problems?

If problems still exist, contact your field representative. Be prepared to provide the following:

- A SMBus trace if possible
- A dump of the EEPROM image. This should be taken from the actual I350, rather than the EEPROM image provided by Intel. Parts of the EEPROM image are changed after writing (such as the physical EEPROM size).

## 10.6 NC-SI Pass Through Interface

The Network Controller Sideband Interface (NC-SI) is a DMTF industry standard protocol for the sideband interface. NC-SI uses a modified version of the industry standard RMII interface for the physical layer as well as defining a new logical layer.

The NC-SI specification can be found at:

<http://www.dmtf.org/>

### 10.6.1 Overview

#### 10.6.1.1 Terminology

The terminology in this document is taken from the NC-SI specification.

**Table 10-29 NC-SI Terminology**

| Term                        | Definition                                                                                                                                                                                        |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frame Versus Packet         | Frame is used in reference to Ethernet, whereas packet is used everywhere else.                                                                                                                   |
| External Network Interface  | The interface of the network controller that provides connectivity to the external network infrastructure (port).                                                                                 |
| Internal Host Interface     | The interface of the network controller that provides connectivity to the Host OS running on the platform.                                                                                        |
| Management Controller (BMC) | An intelligent entity comprising of HW/FW/SW, that resides within a platform and is responsible for some or all management functions associated with the platform (BMC, service processor, etc.). |

**Table 10-29 NC-SI Terminology**

| Term                                  | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Network Controller (NC)               | The component within a system that is responsible for providing connectivity to the external Ethernet network world.                                                                                                                                                                                                                                                                                                                                                  |
| Remote Media                          | The capability to allow remote media devices to appear as if they were attached locally to the Host.                                                                                                                                                                                                                                                                                                                                                                  |
| Network Controller Sideband Interface | The interface of the network controller that provides connectivity to a management controller. It can be shortened to sideband interface as appropriate in the context.                                                                                                                                                                                                                                                                                               |
| Interface                             | This refers to the entire physical interface, such as both the transmit and receive interface between the management controller and the network controller.                                                                                                                                                                                                                                                                                                           |
| Integrated Controller                 | The term integrated controller refers to a network controller device that supports two or more channels for NC-SI that share a common NC-SI physical interface. For example, a network controller that has two or more physical network ports and a single NC-SI bus connection.                                                                                                                                                                                      |
| Multi-Drop                            | Multi-drop commonly refers to the case where multiple physical communication devices share an electrically common bus and a single device acts as the master of the bus and communicates with multiple slave or target devices. In NC-SI, a management controller serves the role as the master, and the network controllers are the target devices.                                                                                                                  |
| Point-to-Point                        | Point-to-point commonly refers to the case where only two physical communication devices are interconnected via a physical communication medium. The devices might be in a master/slave relationship, or could be peers. In NC-SI, point-to-point operation refers to the situation where only a single management controller and single network controller package are used on the bus in a master/slave relationship where the management controller is the master. |
| Channel                               | The control logic and data paths supporting NC-SI pass-through operation on a single network interface (port). A network controller that has multiple network interface ports can support an equivalent number of NC-SI channels.                                                                                                                                                                                                                                     |
| Package                               | One or more NC-SI channels in a network controller that share a common set of electrical buffers and common buffer control for the NC-SI bus. Typically, there will be a single, logical NC-SI package for a single physical network controller package (chip or module). However, the specification allows a single physical chip or module to hold multiple NC-SI logical packages.                                                                                 |
| Control Traffic/Messages/Packets      | Command, response and notification packets transmitted between the BMC and the I350 for the purpose of managing NC-SI.                                                                                                                                                                                                                                                                                                                                                |
| Pass-Through Traffic/Messages/Packets | Non-control packets passed between the external network and the BMC through the I350.                                                                                                                                                                                                                                                                                                                                                                                 |
| Channel Arbitration                   | Refer to operations where more than one of the network controller channels can be enabled to transmit pass-through packets to the BMC at the same time, where arbitration of access to the RXD, CRS_DV, and RX_ER signal lines is accomplished either by software or hardware means.                                                                                                                                                                                  |
| Logically Enabled/Disabled NC         | Refers to the state of the network controller wherein pass-through traffic is able/unable to flow through the sideband interface to and from the management controller, as a result of issuing Enable/Disable Channel command.                                                                                                                                                                                                                                        |
| NC RX                                 | Defined as the direction of ingress traffic on the external network controller interface                                                                                                                                                                                                                                                                                                                                                                              |
| NC TX                                 | Defined as the direction of egress traffic on the external network controller interface                                                                                                                                                                                                                                                                                                                                                                               |
| NC-SI RX                              | Defined as the direction of ingress traffic on the sideband enhanced NC-SI Interface with respect to the network controller.                                                                                                                                                                                                                                                                                                                                          |
| NC-SI TX                              | Defined as the direction of egress traffic on the sideband enhanced NC-SI Interface with respect to the network controller.                                                                                                                                                                                                                                                                                                                                           |

### 10.6.1.2 System Topology

In NC-SI each physical endpoint (NC package) can have several logical slaves (NC channels).

NC-SI defines that one management controller and up to four network controller packages can be connected to the same NC-SI link.

Figure 10-6 shows an example topology for a single BMC and a single NC package. In this example, the NC package has two NC channels.

**Figure 10-6** Single NC Package, Two NC Channels

Figure 10-7 shows an example topology for a single BMC and two NC packages. In this example, one NC package has two NC channels and the other has only one NC channel. Scenarios in which the NC-SI lines are shared by multiple NCs (Figure 10-7) mandate an arbitration mechanism. The arbitration mechanism is described in Section 10.6.8.1.

**Figure 10-7** Two NC Packages (Left, with Two NC Channels and Right, with One NC Channel)

**Note:** Channel numbers should match PCI function numbers. So when PCI functions are swapped (FACTPS.LAN Function Sel == 1), then the channels should be swapped also.

### 10.6.1.3 Data Transport

Since NC-SI is based upon the RMIi transport layer, data is transferred in the form of Ethernet frames.

NC-SI defines two types of transmitted frames:

1. Control frames:
  - a. Configures and control the interface
  - b. Identified by a unique EtherType in their L2 header
2. Pass-through frames:
  - a. Actual LAN pass-through frames transferred from/to the BMC
  - b. Identified as not being a control frame
  - c. Attributed to a specific NC channel by their source MAC address (as configured in the NC by the BMC)

**Note:** The NC-SI spec allows reception of data packets up to 1536 bytes. However, the I350 allows only legal Ethernet packets to pass. So packets larger than 1518 bytes plus optional VLAN headers will be dropped.

#### 10.6.1.3.1 Control Frames

NC-SI control frames are identified by a unique NC-SI EtherType (0x88F8).

Control frames are used in a single-threaded operation, meaning commands are generated only by the BMC and can only be sent one at a time. Each command from the BMC is followed by a single response from the NC (command-response flow), after which the BMC is allowed to send a new command.

The only exception to the command-response flow is the Asynchronous Event Notification (AEN). These control frames are sent unsolicited from the NC to the BMC.

AEN functionality by the NC must be disabled by default, until activated by the BMC using the Enable AEN commands.

In order to be considered a valid command, a control frame must:

1. Comply with the NC-SI header format.
2. Be targeted to a valid channel in the package via the Package ID and Channel ID fields. For example, to target a NC channel with package ID of 0x2 and internal channel ID of 0x5, the BMC must set the channel ID inside the control frame to 0x45. The channel ID is composed of three bits of package ID and five bits of internal channel ID.
3. Contain a correct payload checksum (if used).
4. Meet any other condition defined by NC-SI.

There are also commands (such as select package) targeted to the package as a whole. These commands must use an internal channel ID of 0x1F.

For details, refer to the NC-SI specification.

#### 10.6.1.3.2 NC-SI Frames Receive Flow

Figure 10-8 shows the flow for frames received on the NC from the BMC.

**Figure 10-8 NC-SI Frames Receive Flow for the NC**

## 10.6.2 Supported Features

The I350 supports all the mandatory features of the NC-SI specification (rev 1.0.0). Table 10-30 lists the supported commands.

Table 10-31 lists optional features supported.

**Table 10-30 Supported NC-SI Commands**

| Command                          | Supported over RMII  | Supported over MCTP |
|----------------------------------|----------------------|---------------------|
| Clear initial state              | Yes                  | Yes                 |
| Get Version ID                   | Yes                  | Yes                 |
| Get Parameters                   | Yes                  | Yes                 |
| Get Controller Packet Statistics | Yes, partially       | Yes, partially      |
| Get Link Status <sup>1</sup>     | Yes                  | Yes                 |
| Enable Channel                   | Yes                  | Yes <sup>2</sup>    |
| Disable Channel                  | Yes                  | Yes <sup>2</sup>    |
| Reset Channel                    | Yes                  | Yes <sup>2</sup>    |
| Enable VLAN                      | Yes <sup>1,3/4</sup> | No <sup>2</sup>     |
| Disable VLAN                     | Yes                  | No <sup>2</sup>     |
| Enable Broadcast Filter          | Yes                  | No <sup>2</sup>     |
| Disable Broadcast Filter         | Yes                  | No <sup>2</sup>     |
| Set MAC Address                  | Yes                  | No <sup>2</sup>     |

**Table 10-30 Supported NC-SI Commands (Continued)**

| Command                           | Supported over RMII | Supported over MCTP |
|-----------------------------------|---------------------|---------------------|
| Get NC-SI Statistics              | Yes, partially      | Yes, partially      |
| Set NC-SI Flow-Control            | Yes                 | No                  |
| Set Link Command                  | Yes                 | Yes                 |
| Enable Global multicast Filter    | Yes                 | No <sup>2</sup>     |
| Disable Global multicast Filter   | Yes                 | No <sup>2</sup>     |
| Get Capabilities                  | Yes                 | Yes <sup>5</sup>    |
| Set VLAN Filters                  | Yes                 | No <sup>2</sup>     |
| AEN Enable                        | Yes                 | Yes                 |
| Get NC-SI Pass-Through Statistics | Yes, partially      | No <sup>2</sup>     |
| Select Package                    | Yes                 | Yes                 |
| Deselect Package                  | Yes                 | Yes                 |
| Enable Channel Network TX         | Yes                 | No                  |
| Disable Channel Network TX        | Yes                 | No                  |
| OEM Command <sup>6</sup>          | Yes                 | Yes                 |

1. When working with SGMII interface, this command is not supported.
2. In MCTP over SMBus mode, only control commands are supported and not pass through traffic - thus many of the regular NC-SI commands are not supported or are supported in a limited manner, only to allow control and status reporting for the device.
3. When one of the LAN devices is assigned for the sole use of the manageability and its LAN PCI-E function is disabled, using the NC-SI Set Link command while advertising multiple speeds and enabling Auto-Negotiation, will result in the lowest possible speed chosen. To enable higher link speed, the BMC should not advertise speeds that are below the desired link speed. When doing it, changing the power state of the LAN device will have no effect and the link speed will not be re-negotiated.
4. The I350 does not support filtering of User priority/CFI Bits of VLAN
5. When the "Get Capabilities" command is received over MCTP, the I350 returns the full filtering capabilities reported over RMII even that pass through is not available via MCTP.
6. See [Section 10.6.3](#) for details.

**Table 10-31 Optional NC-SI Features Support**

| Feature                                  | Implement      | Details                                                                                                    |
|------------------------------------------|----------------|------------------------------------------------------------------------------------------------------------|
| AENs                                     | Yes            | The Driver state AEN may be emitted up to 15 sec. after actual driver change.                              |
| Get Controller Packet Statistics command | Yes, partially | Supports the following counters <sup>1</sup> : 2-9,13-16 <sup>2</sup>                                      |
| Get NC-SI statistics                     | Yes, partially | Support the following counters: <sup>3</sup> 1-4, 7 <sup>4</sup> .                                         |
| Get NC-SI Pass-Through Statistics        | Yes, partially | Support the following counters: 2.<br>Support the following counters only when the OS is down:<br>1, 6, 7. |
| VLAN Modes                               | Yes, partially | Support only modes 1, 3.                                                                                   |
| Buffering Capabilities                   | Yes            | 8Kb                                                                                                        |
| MAC Address Filters                      | Yes            | Supports 2 mixed MAC addresses per port.                                                                   |
| Channel Count                            | Yes            | Supports 4 channels.                                                                                       |
| VLAN Filters                             | Yes            | Support 8 VLAN filters per port.<br>Filtering is ignoring the CFI bit and the 802.1P priority bits         |

**Table 10-31 Optional NC-SI Features Support**

| Feature              | Implement | Details                                                                                                                                        |
|----------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Broadcast Filters    | Yes       | Support the following filters:<br>ARP<br>DHCP<br>Net BIOS                                                                                      |
| Multicast Filters    | Yes       | Supports the following filters <sup>5</sup> :<br>IPv6 Neighbor Advertisement<br>IPv6 Router Advertisement<br>DHCPv6 relay and server multicast |
| Hardware Arbitration | Yes       | Supports NC-SI HW arbitration.                                                                                                                 |

1. *TCTL.EN* should be set to 1b to activate TX related counters and *RCTL.RXEN*, *MANC.RCV\_EN* or *WUC.APME* should be set to enable RX related counters.
2. As described in the Get Controller Packet Statistics Counter Numbers table in NC-SI spec.
3. The I350 does not increment the NC-SI Control Packets Dropped counter when packets with Checksum errors are dropped. In this case, only the NC-SI Command Checksum Errors counter is updated.
4. As described in Get NC-SI Statistics Response Counters table in NC-SI spec.
5. Supports only when all three filters are enabled.

### 10.6.2.1 Set Link Error Codes

The following rules are used to define the error code returned for Set Link command in case an invalid configuration is requested:

1. Host Driver Check: If host device driver is present, return a Command Specific Response (0x9) with a Set Link Host OS/Driver Conflict Reason (0x1).
2. Speed Present Check: If no speed is selected, return a General Reason Code for a failed command (0x1) with Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).
3. Parameter Validity:
  - a. Auto Negotiation Parameter Validation: If Auto Negotiation is requested and none of the selected parameters are valid for the device, return a General Reason Code for a failed command (0x1) with a Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).

**Note:** This means that, for example, a command requesting 10G on a 1G device will succeed provided that the command requests at least one other supported speed. The same goes for an unsupported duplex setting (a device with no HD support will accept a command with both FD and HD set), and also for HD being requested with speeds of 1G and higher as long as a speed below 1G is also requested (and is supported in HD). The device will simply ignore the unsupported parameters.

- b. Force Mode Parameter Validation:
  1. If more than one link speed is being forced, then return a General Reason Code for a failed command (0x1) and a Command Specific Reason with a Set Link Speed Conflict Reason (0x0905).
  2. If more than one duplex setting is being forced, then return a General Reason Code for a failed command (0x1) with Parameter Is Invalid, Unsupported, or Out-of-Range Reason (0x2).
  3. If 1G and above is requested with HD, then return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Parameter Conflict Error (0x0903).
4. Media Type Compatibility Check: If current media type is not compatible for the requested link parameters, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Media Conflict Error (0x0902).

5. Power State Compatibility Check: If current power state does not allow for the requested link parameters, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Set Link Power Mode Conflict Error (0x0904).
6. If for some reason the hardware cannot perform the flow required for the command, return a General Reason Code for a failed command (0x1) and a Command Specific Reason with Link Command Failed-Hardware Access Error (0x0906).

## 10.6.3 NC-SI Mode — Intel Specific Commands

In addition to regular NC-SI commands, the following Intel vendor specific commands are supported. The purpose of these commands is to provide a means for the BMC to access some of the Intel-specific features present in the I350.

### 10.6.3.1 Overview

The following features are available via the NC-SI OEM specific commands:

- Receive filters:
  - Packet Addition Decision Filters 0x0...0x4
  - Packet Reduction Decision Filters 0x5...0x7
  - *MNGONLY* register (controls the forwarding of manageability packets to the Host)
  - Flex 128 filter
  - Flex TCP/UDP port filters 0x0...0x2
  - IPv4/IPv6 filters
- Get System MAC Address — This command enables the BMC to retrieve the system MAC address used by the NC. This MAC address can be used for a shared MAC address mode.
- Keep PHY Link Up (Veto bit) Enable/Disable — This feature enables the BMC to block PHY reset, which might cause session loss.
- TCO Reset — Enables the BMC to reset the I350.
- Checksum offloading — Offloads IP/UDP/TCP checksum checking from the BMC.

These commands are designed to be compliant with their corresponding SMBus commands (if existing). All of the commands are based on a single DMTF defined NC-SI command, known as OEM Command. This command is as follows.

#### 10.6.3.1.1 OEM Command (0x50)

The OEM command can be used by the BMC to request the sideband interface to provide vendor-specific information.

|         | Bits                          |       |               |       |
|---------|-------------------------------|-------|---------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08         | 07:00 |
| 00...15 | NC-SI Header                  |       |               |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |               |       |
| 20...   | Intel Command Number          |       | Optional Data |       |

### 10.6.3.1.2 OEM Response (0xD0)

|         | Bits                          |                      |             |       |
|---------|-------------------------------|----------------------|-------------|-------|
| Bytes   | 31:24                         | 23:16                | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |                      |             |       |
| 16...19 | Response Code                 |                      | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |                      |             |       |
| 24...27 | Intel Command Number          | Optional Return Data |             |       |

**Note:** Responses have no command-specific reason code, unless otherwise specified within the command.

### 10.6.3.2 Command Summary

**Table 10-32 OEM Specific Command Response and Reason Codes**

| Response Code |                | Reason Code |                                        |
|---------------|----------------|-------------|----------------------------------------|
| Value         | Description    | Value       | Description                            |
| 0x1           | Command Failed | 0x5081      | Invalid Intel Command Number           |
|               |                | 0x5082      | Invalid Intel Command Parameter Number |
|               |                | 0x5087      | Invalid Driver State                   |
|               |                | 0x5088      | Invalid EEPROM                         |

**Table 10-33 Command Summary**

| Intel Command | Parameter | Command Name                            | Supported in MCTP |
|---------------|-----------|-----------------------------------------|-------------------|
| 0x00          | 0x00      | Set IP Filters Control                  | No                |
| 0x01          | 0x00      | Get IP Filters Control                  | No                |
| 0x02          | 0x0F      | Set Manageability Only                  | No                |
|               | 0x10      | Set Flexible 128 Filter Mask and Length |                   |
|               | 0x11      | Set Flexible 128 Filter Data            |                   |
|               | 0x61      | Set Packet Addition Filters             |                   |
|               | 0x63      | Set Flex TCP/UDP Port Filters           |                   |
|               | 0x64      | Set Flex IPv4 Address Filters           |                   |
|               | 0x65      | Set Flex IPv6 Address Filters           |                   |
|               | 0x67      | Set EtherType Filter                    |                   |
|               | 0x68      | Set Packet Addition Extended Filter     |                   |

**Table 10-33 Command Summary (Continued)**

| Intel Command | Parameter | Command Name                                    | Supported in MCTP |
|---------------|-----------|-------------------------------------------------|-------------------|
| 0x03          | 0x0F      | Get Manageability Only                          | No                |
|               | 0x10      | Get Flexible 128 Filter Mask and Length         |                   |
|               | 0x11      | Get Flexible 128 Filter Data                    |                   |
|               | 0x61      | Get Packet Addition Filters                     |                   |
|               | 0x63      | Get Flex TCP/UDP Port Filters                   |                   |
|               | 0x64      | Get Flex IPv4 Address Filters                   |                   |
|               | 0x65      | Get Flex IPv6 Address Filters                   |                   |
|               | 0x67      | Get EtherType Filter                            |                   |
|               | 0x68      | Get Packet Addition Extended Filter             |                   |
| 0x04          | 0x00      | Set Unicast Packet Reduction                    | No                |
|               | 0x01      | Set Multicast Packet Reduction                  |                   |
|               | 0x02      | Set Broadcast Packet Reduction                  |                   |
|               | 0x10      | Set Extended Unicast Packet Reduction           |                   |
|               | 0x11      | Set Extended Multicast Packet Reduction         |                   |
|               | 0x12      | Set Extended Broadcast Packet Reduction         |                   |
| 0x05          | 0x00      | Get Unicast Packet Reduction                    | No                |
|               | 0x01      | Get Multicast Packet Reduction                  |                   |
|               | 0x02      | Get Broadcast Packet Reduction                  |                   |
|               | 0x10      | Get Extended Unicast Packet Reduction           |                   |
|               | 0x11      | Get Extended Multicast Packet Reduction         |                   |
|               | 0x12      | Get Extended Broadcast Packet Reduction         |                   |
| 0x06          | N/A       | Get System MAC Address                          | Yes               |
| 0x20          | N/A       | Set Intel Management Control                    | No                |
| 0x21          | N/A       | Get Intel Management Control                    | No                |
| 0x22          | N/A       | Perform TCO Reset                               | Yes               |
| 0x23          | N/A       | Enable IP/UDP/TCP Checksum Offloading           | No                |
| 0x24          | N/A       | Disable IP/UDP/TCP Checksum Offloading          | No                |
| 0x40          | 0x01      | Enable OS2BMC flow                              | No                |
|               | 0x02      | Enable Network to BMC flow                      |                   |
|               | 0x03      | Enable Both Network to BMC and Host to BMC flow |                   |
| 0x41          | N/A       | Get OS2BMC parameters                           | No                |
| 0x48          | 0x1       | Get Controller information                      | Yes               |
| 0x4C          | 0x0       | Get Thermal Sensor Capabilities                 | Yes               |
|               | 0x1       | Get Thermal Sensor Configuration                | Yes               |
|               | 0x2       | Get Thermal Sensor Status                       | Yes               |
| 0x4D          | 0x1       | Set Thermal Sensor Configuration                | Yes               |
|               | 0x2       | Perform Thermal Action                          | Yes               |

### 10.6.3.3 Set Intel Filters Control — IP Filters Control Command (Intel Command 0x00, Filter Control Index 0x00)

This command controls different aspects of the Intel filters.

|         | Bits                          |       |                          |       |
|---------|-------------------------------|-------|--------------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                    | 07:00 |
| 00...15 | NC-SI Header                  |       |                          |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                          |       |
| 20...23 | 0x00                          | 0x00  | IP Filters control (3-2) |       |
| 24...25 | IP Filters Control (1-0)      |       |                          |       |

Where “IP Filters Control” has the following format.

**Table 10-34 IP Filters Control**

| Bit #  | Name           | Description                                                                                                                                                                                                           | Default Value |
|--------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| 0      | IPv4/IPv6 Mode | IPv6 (0b): There are zero IPv4 filters and four IPv6 filters<br>IPv4 (1b): There are four IPv4 filters and three IPv6 filters.<br>See <a href="#">Section 8.21.8</a> or <a href="#">Section 10.3.3.6</a> for details. | 1b            |
| 1...31 | Reserved       |                                                                                                                                                                                                                       |               |

### 10.6.3.3.1 Set Intel Filters Control — IP Filters Control Response (Intel Command 0x00, Filter Control Index 0x00)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...27 | 0x00                          | 0x00  |             |       |

### 10.6.3.4 Get Intel Filters Control Commands (Intel Command 0x01)

#### 10.6.3.4.1 Get Intel Filters Control — IP Filters Control Command (Intel Command 0x01, Filter Control Index 0x00)

This command reflects different aspects of the Intel filters.

|       | Bits  |       |       |       |
|-------|-------|-------|-------|-------|
| Bytes | 31:24 | 23:16 | 15:08 | 07:00 |

|         |                               |      |  |
|---------|-------------------------------|------|--|
| 00...15 | NC-SI Header                  |      |  |
| 16...19 | Manufacturer ID (Intel 0x157) |      |  |
| 20...21 | 0x01                          | 0x00 |  |

#### 10.6.3.4.2 Get Intel Filters Control — IP Filters Control Response (Intel Command 0x01, Filter Control Index 0x00)

|         | Bits                          |       |                          |       |
|---------|-------------------------------|-------|--------------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                    | 07:00 |
| 00...15 | NC-SI Header                  |       |                          |       |
| 16...19 | Response Code                 |       | Reason Code              |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                          |       |
| 24...27 | 0x01                          | 0x00  | IP Filters Control (3-2) |       |
| 28...29 | IP Filters Control (1-0)      |       |                          |       |

IP Filter Control: See [Table 10-34](#).

### 10.6.3.5 Set Intel Filters Formats

#### 10.6.3.5.1 Set Intel Filters Command (Intel Command 0x02)

|         | Bits                          |                  |                         |       |
|---------|-------------------------------|------------------|-------------------------|-------|
| Bytes   | 31:24                         | 23:16            | 15:08                   | 07:00 |
| 00...15 | NC-SI Header                  |                  |                         |       |
| 16...19 | Manufacturer ID (Intel 0x157) |                  |                         |       |
| 20...21 | 0x02                          | Parameter Number | Filters Data (optional) |       |

#### 10.6.3.5.2 Set Intel Filters Response (Intel Command 0x02)

|         | Bits                          |                      |                        |       |
|---------|-------------------------------|----------------------|------------------------|-------|
| Bytes   | 31:24                         | 23:16                | 15:08                  | 07:00 |
| 00...15 | NC-SI Header                  |                      |                        |       |
| 16...19 | Response Code                 |                      | Reason Code            |       |
| 20...23 | Manufacturer ID (Intel 0x157) |                      |                        |       |
| 24...   | 0x02                          | Filter Control Index | Return Data (Optional) |       |

#### 10.6.3.5.3 Set Intel Filters — Manageability Only Command (Intel Command 0x02, Filter Parameter 0x0F)

This command sets the *MNGONLY* register. The *MNGONLY* register controls whether pass-through packets destined to the BMC are not forwarded to the Host OS. The *MNGONLY* register structure is described in [Table 10-4](#).

|         | Bits                          |       |                          |       |
|---------|-------------------------------|-------|--------------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                    | 07:00 |
| 00...15 | NC-SI Header                  |       |                          |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                          |       |
| 20...23 | 0x02                          | 0x0F  | Manageability Only (3-2) |       |
| 24...25 | Manageability Only (1-0)      |       |                          |       |

#### 10.6.3.5.4 Set Intel Filters — Manageability Only Response (Intel Command 0x02, Filter Parameter 0x0F)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x02                          | 0x0F  |             |       |

#### 10.6.3.5.5 Set Intel Filters — Flex Filter Enable Mask and Length Command (Intel Command 0x02, Filter Parameter 0x10)

The following command sets the Intel flex filters mask and length. See [Section 10.3.3.5](#) for details of the programming.

|         | Bits                          |              |             |             |
|---------|-------------------------------|--------------|-------------|-------------|
| Bytes   | 31:24                         | 23:16        | 15:08       | 07:00       |
| 00...15 | NC-SI Header                  |              |             |             |
| 16...19 | Manufacturer ID (Intel 0x157) |              |             |             |
| 20...23 | 0x02                          | 0x10         | Mask Byte 1 | Mask Byte 2 |
| 24...27 | ...                           | ...          | ...         | ...         |
| 28...31 | ...                           | ...          | ...         | ...         |
| 32...35 | ...                           | ...          | ...         | ...         |
| 36...37 | ...                           | Mask Byte 16 | Reserved    | Reserved    |
| 38      | Length                        |              |             |             |

### 10.6.3.5.6 Set Intel Filters — Flex Filter Enable Mask and Length Response (Intel Command 0x02, Filter Parameter 0x10)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x02                          | 0x10  |             |       |

### 10.6.3.5.7 Set Intel Filters — Flex Filter Data Command (Intel Command 0x02, Filter Parameter 0x11)

|         | Bits                          |               |                   |               |
|---------|-------------------------------|---------------|-------------------|---------------|
| Bytes   | 31:24                         | 23:16         | 15:08             | 07:00         |
| 00...15 | NC-SI Header                  |               |                   |               |
| 16...19 | Manufacturer ID (Intel 0x157) |               |                   |               |
| 20...   | 0x02                          | 0x11          | Filter Data Group | Filter Data 1 |
|         | ...                           | Filter Data N |                   |               |

The Filter Data Group parameter defines which bytes of the Flex filter are set by this command:

**Table 10-35 Filter Data Group**

| Code | Bytes programmed | Filter Data Length |
|------|------------------|--------------------|
| 0x0  | bytes 0-29       | 1 - 30             |
| 0x1  | bytes 30-59      | 1 - 30             |
| 0x2  | bytes 60-89      | 1 - 30             |
| 0x3  | bytes 90-119     | 1 - 30             |
| 0x4  | bytes 120-127    | 1 - 8              |

**Note:** Using this command to configure the filters data must be done after the flex filter mask command is issued and the mask is set.

### 10.6.3.5.8 Set Intel Filters — Flex Filter Data Response (Intel Command 0x02, Filter Parameter 0x11)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x02                          | 0x11  |             |       |

**Note:** If Filter Data Length is larger than specified in [Table 10-35](#) an Out of Range Reason code is returned.

### 10.6.3.5.9 Set Intel Filters — Packet Addition Decision Filter Command (Intel Command 0x02, Filter Parameter 0x61)

**Note:** This command is kept and supported for legacy reasons, however it is recommended to use the Set Intel Filters - Packet Addition Extended Decision Filter Command (Intel Command 0x02, Filter parameter 0x68 - [Section 10.6.3.5.19](#)) instead.

|         | Bits                          |       |                       |                       |
|---------|-------------------------------|-------|-----------------------|-----------------------|
| Bytes   | 31:24                         | 23:16 | 15:08                 | 07:00                 |
| 00...15 | NC-SI Header                  |       |                       |                       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                       |                       |
| 20...23 | 0x02                          | 0x61  | Filter index          | Decision Filter (MSB) |
| 24...25 | .....                         |       | Decision Filter (LSB) |                       |

Filter index range: 0x0...0x4.

**Note:** If the filter index is bigger than 4, a command failed Response Code is returned with no reason.

**Table 10-36 Filter Values**

| Bit # | Name                    | Description                                                                                   |
|-------|-------------------------|-----------------------------------------------------------------------------------------------|
| 3:0   | Exact (AND)             | If set, packets must match exact filter 0 to 3 respectively.                                  |
| 4     | Broadcast (AND)         | If set, packets must match the broadcast filter.                                              |
| 12:5  | VLAN (AND)              | If set, packets must match VLAN filter 0 to 7 respectively.                                   |
| 16:13 | IPv4 Address (AND)      | If set, packets must match IPv4 filter 0 to 3 respectively                                    |
| 20:17 | IPv6 Address (AND)      | If set, packets must match IPv4 filter 0 to 3 respectively                                    |
| 24:21 | Exact (OR)              | If set, packets must match exact filter 0 to 3 respectively or a different OR filter.         |
| 25    | Broadcast (OR)          | If set, packets can pass if match the broadcast filter or a different OR filter.              |
| 26    | Multicast (AND)         | If set, packets must match the multicast filter.                                              |
| 27    | ARP Request (OR)        | If set, packets can pass if match the ARP request filter or a different OR filter.            |
| 28    | ARP Response (OR)       | If set, packets can pass if match the ARP response filter or a different OR filter.           |
| 29    | Neighbor Discovery (OR) | If set, packets can pass if match the neighbor discovery filter or a different OR filter.     |
| 30    | Port 0x298 (OR)         | If set, packets can pass if match a fixed TCP/UDP port 0x298 filter or a different OR filter. |
| 31    | Port 0x26F (OR)         | If set, packets can pass if match a fixed TCP/UDP port 0x26F filter or a different OR filter. |

The filtering is done according to the mechanism described in [Section 10.3.4.1](#).

**Note:** These filter settings operate according to the VLAN mode, as configured according to the DMTF NC-SI specification. After disabling packet reduction filters, the BMC must re-set the VLAN mode using the Set VLAN command.

### 10.6.3.5.10 Set Intel Filters — Packet Addition Decision Filter Response (Intel Command 0x02, Filter Parameter 0x61)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x02                          | 0x61  |             |       |

### 10.6.3.5.11 Set Intel Filters — Flex TCP/UDP Port Filter Command (Intel Command 0x02, Filter Parameter 0x63)

|         | Bits                          |       |                   |                  |
|---------|-------------------------------|-------|-------------------|------------------|
| Bytes   | 31:24                         | 23:16 | 15:08             | 07:00            |
| 00...15 | NC-SI Header                  |       |                   |                  |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                   |                  |
| 20...23 | 0x02                          | 0x63  | Port filter index | TCP/UDP Port MSB |
| 24      | TCP/UDP Port LSB              |       |                   |                  |

Filter index range: 0x0...0x2.

If the filter index is bigger than 2, a command failed Response Code is returned with no reason.

### 10.6.3.5.12 Set Intel Filters — Flex TCP/UDP Port Filter Response (Intel Command 0x02, Filter Parameter 0x63)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x02                          | 0x63  |             |       |

### 10.6.3.5.13 Set Intel Filters — IPv4 Filter Command (Intel Command 0x02, Filter Parameter 0x64)

|         | Bits                          |       |                    |                    |
|---------|-------------------------------|-------|--------------------|--------------------|
| Bytes   | 31:24                         | 23:16 | 15:08              | 07:00              |
| 00...15 | NC-SI Header                  |       |                    |                    |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                    |                    |
| 20...23 | 0x02                          | 0x64  | IP filter index    | IPv4 Address (MSB) |
| 24...25 | ...                           |       | IPv4 Address (LSB) |                    |

IPv4 Mode: Filter index range: 0x0...0x3.

IPv6 Mode: This command should not be used in IPv6 mode.

#### 10.6.3.5.14 Set Intel Filters — IPv4 Filter Response (Intel Command 0x02, Filter Parameter 0x64)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x02                          | 0x64  |             |       |

#### 10.6.3.5.15 Set Intel Filters — IPv6 Filter Command (Intel Command 0x02, Filter Parameter 0x65)

|         | Bits                          |       |                            |                                |
|---------|-------------------------------|-------|----------------------------|--------------------------------|
| Bytes   | 31:24                         | 23:16 | 15:08                      | 07:00                          |
| 00...15 | NC-SI Header                  |       |                            |                                |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                            |                                |
| 20...23 | 0x02                          | 0x65  | IP filter index            | ...IPv6 Address (MSB, byte 15) |
| 24...27 | ...                           | ...   | ...                        | ...                            |
| 28...31 | ...                           | ...   | ...                        | ...                            |
| 32...35 | ...                           | ...   | ...                        | ...                            |
| 36...37 | ...                           |       | IPv6 Address (LSB, byte 0) |                                |

**Note:** The filters index range can vary according to the IPv4/IPv6 mode setting in the Filters Control command.

IPv4 Mode: Filter index range: 0x0...0x2.

IPv6 Mode: Filter index range: 0x0...0x3.

#### 10.6.3.5.16 Set Intel Filters — IPv6 Filter Response (Intel Command 0x02, Filter Parameter 0x65)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x02                          | 0x65  |             |       |

If the IP filter index is larger the 3, a command failed Response Code will be returned, with no reason.

#### 10.6.3.5.17 Set Intel Filters - EtherType Filter Command (Intel Command 0x02, Filter parameter 0x67)

|         | Bits                          |       |                        |                      |
|---------|-------------------------------|-------|------------------------|----------------------|
| Bytes   | 31:24                         | 23:16 | 15:08                  | 07:00                |
| 00...15 | NC-SI Header                  |       |                        |                      |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                        |                      |
| 20...23 | 0x02                          | 0x67  | EtherType Filter Index | EtherType Filter MSB |
| 24...27 | ...                           | ...   | EtherType Filter LSB   |                      |

Where the EtherType Filter has the format as described in [Section 8.21.3](#).

#### 10.6.3.5.18 Set Intel Filters - EtherType Filter Response (Intel Command 0x02, Filter parameter 0x67)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x02                          | 0x67  |             |       |

If the Ethertype filter Index is greater than 3, a command failed Response Code is returned with no reason.

#### 10.6.3.5.19 Set Intel Filters - Packet Addition Extended Decision Filter Command (Intel Command 0x02, Filter parameter 0x68)

See [Figure 10-2](#) for description of the decision filters structure.

The command shall overwrite any previously stored value.

**Note:** Previous "Set Intel Filters – Packet Addition Decision Filter" command (0x61) is kept and supported for legacy reasons - If previous "Decision Filter" command is called – it should set the Decision Filter 0 as provided. The extended Decision Filter remains unchanged. However, it is recommended to use this set of commands for packet addition.

|         | Bits                          |       |                                |                                |
|---------|-------------------------------|-------|--------------------------------|--------------------------------|
| Bytes   | 31:24                         | 23:16 | 15:08                          | 07:00                          |
| 00...15 | NC-SI Header                  |       |                                |                                |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                                |                                |
| 20...23 | 0x02                          | 0x68  | Extended Decision filter Index | Extended Decision filter 1 MSB |
| 24...27 | ...                           | ...   | Extended Decision filter 1 LSB | Extended Decision filter 0 MSB |
| 28...30 | ...                           | ...   | Extended Decision filter 0 LSB |                                |

Extended Decision filter Index Range: 0...4

Filter 0: See [Table 10-37](#).

Filter 1: See [Table 10-38](#).

**Table 10-37 Filter Values**

| Bit # | Name                    | Description                                                                                   |
|-------|-------------------------|-----------------------------------------------------------------------------------------------|
| 3:0   | Exact (AND)             | If set, packets must match exact filter 0 to 3 respectively.                                  |
| 4     | Broadcast (AND)         | If set, packets must match the broadcast filter.                                              |
| 12:5  | VLAN (AND)              | If set, packets must match VLAN filter 0 to 7 respectively.                                   |
| 16:13 | IPv4 Address (AND)      | If set, packets must match IPv4 filter 0 to 3 respectively                                    |
| 20:17 | IPv6 Address (AND)      | If set, packets must match IPv4 filter 0 to 3 respectively                                    |
| 24:21 | Exact (OR)              | If set, packets must match exact filter 0 to 3 respectively or a different OR filter.         |
| 25    | Broadcast (OR)          | If set, packets can pass if match the broadcast filter or a different OR filter.              |
| 26    | Multicast (AND)         | If set, packets must match the multicast filter.                                              |
| 27    | ARP Request (OR)        | If set, packets can pass if match the ARP request filter or a different OR filter.            |
| 28    | ARP Response (OR)       | If set, packets can pass if match the ARP response filter or a different OR filter.           |
| 29    | Neighbor Discovery (OR) | If set, packets can pass if match the neighbor discovery filter or a different OR filter.     |
| 30    | Port 0x298 (OR)         | If set, packets can pass if match a fixed TCP/UDP port 0x298 filter or a different OR filter. |
| 31    | Port 0x26F (OR)         | If set, packets can pass if match a fixed TCP/UDP port 0x26F filter or a different OR filter. |

**Table 10-38 Extended Filter Values**

| Bit # | Name                 | Description                                                                                          |
|-------|----------------------|------------------------------------------------------------------------------------------------------|
| 3:0   | Ethertype 0 -3 (AND) | If set, packets must match the Ethertype filter 0 to 3 respectively.                                 |
| 7:4   | Reserved             | Reserved                                                                                             |
| 11:8  | Ethertype 0 -3 (OR)  | If set, packets can pass if match the Ethertype filter 0 to 3 respectively or a different OR filter. |
| 15:12 | Reserved             | Reserved                                                                                             |
| 16    | Flex port 0 (OR)     | If set, packets can pass if match the TCP/UDP Port filter 0                                          |

**Table 10-38 Extended Filter Values (Continued)**

| Bit # | Name                          | Description                                                                  |
|-------|-------------------------------|------------------------------------------------------------------------------|
| 17    | Flex port 1 (OR)              | If set, packets can pass if match the TCP/UDP Port filter 1                  |
| 18    | Flex port 2 (OR)              | If set, packets can pass if match the TCP/UDP Port filter 2                  |
| 19    | DHCPv6 (OR)                   | If set, packets can pass if match the DHCPv6 port (0x0223)                   |
| 20    | DHCP Client (OR)              | If set, packets can pass if match the DHCP Server port (0x0043)              |
| 21    | DHCP Server (OR)              | If set, packets can pass if match the DHCP Client port (0x0044)              |
| 22    | NetBIOS Name Service (OR)     | If set, packets can pass if match the NetBIOS Name Service port (0x0089)     |
| 23    | NetBIOS Datagram Service (OR) | If set, packets can pass if match the NetBIOS Datagram Service port (0x008A) |
| 24    | Flex TCO (OR)                 | If set, packets can pass if match the Flex 128 TCO filter                    |
| 31:25 | Reserved                      |                                                                              |

### 10.6.3.5.20 Set Intel Filters – Packet Addition Extended Decision Filter Response (Intel Command 0x02, Filter parameter 0x68)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x02                          | 0x68  |             |       |

If the Extended Decision filter Index is bigger than 5, a command failed Response Code is returned with no reason.

## 10.6.3.6 Get Intel Filters Formats

### 10.6.3.6.1 Get Intel Filters Command (Intel Command 0x03)

|         | Bits                          |                  |       |       |
|---------|-------------------------------|------------------|-------|-------|
| Bytes   | 31:24                         | 23:16            | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |                  |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |                  |       |       |
| 20...21 | 0x03                          | Parameter Number |       |       |

### 10.6.3.6.2 Get Intel Filters Response (Intel Command 0x03)

|         | Bits         |       |       |       |
|---------|--------------|-------|-------|-------|
| Bytes   | 31:24        | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header |       |       |       |

|         |                               |                      |
|---------|-------------------------------|----------------------|
| 16...19 | Response Code                 | Reason Code          |
| 20...23 | Manufacturer ID (Intel 0x157) |                      |
| 24...25 | 0x03                          | Optional Return Data |

### 10.6.3.6.3 Get Intel Filters — Manageability Only Command (Intel Command 0x03, Filter Parameter 0x0F)

This command retrieves the *MNGONLY* register. The *MNGONLY* register controls whether pass-through packets destined to the BMC are also be forwarded to the Host OS.

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x03                          | 0x0F  |       |       |

### 10.6.3.6.4 Get Intel Filters — Manageability Only Response (Intel Command 0x03, Filter Parameter 0x0F)

The *MNGONLY* register structure is described in [Table 10-4](#).

|         | Bits                          |             |                          |       |
|---------|-------------------------------|-------------|--------------------------|-------|
| Bytes   | 31:24                         | 23:16       | 15:08                    | 07:00 |
| 00...15 | NC-SI Header                  |             |                          |       |
| 16...19 | Response Code                 | Reason Code |                          |       |
| 20...23 | Manufacturer ID (Intel 0x157) |             |                          |       |
| 24...27 | 0x03                          | 0x0F        | Manageability Only (3-2) |       |
| 28...29 | Manageability Only(1-0)       |             |                          |       |

### 10.6.3.6.5 Get Intel Filters — Flex Filter 0 Enable Mask and Length Command (Intel Command 0x03, Filter Parameter 0x10)

The following command retrieves the Intel flex filters mask and length. See [Section 10.3.3.5](#) for details of the values returned by this command.

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x03                          | 0x10  |       |       |

### 10.6.3.6.6 Get Intel Filters — Flex Filter 0 Enable Mask and Length Response (Intel Command 0x03, Filter Parameter 0x10)

|         | Bits                          |              |             |             |
|---------|-------------------------------|--------------|-------------|-------------|
| Bytes   | 31:24                         | 23:16        | 15:08       | 07:00       |
| 00...15 | NC-SI Header                  |              |             |             |
| 16...19 | Response Code                 |              | Reason Code |             |
| 20...23 | Manufacturer ID (Intel 0x157) |              |             |             |
| 24...27 | 0x03                          | 0x10         | Mask Byte 1 | Mask Byte 2 |
| 28...31 | ...                           | ...          | ...         | ...         |
| 32...35 | ...                           | ...          | ...         | ...         |
| 36...39 | ...                           | ...          | ...         | ...         |
| 40...43 | ...                           | Mask Byte 16 | Reserved    | Reserved    |
| 44      | Flexible Filter Length        |              |             |             |

### 10.6.3.6.7 Get Intel Filters — Flex Filter 0 Data Command (Intel Command 0x03, Filter Parameter 0x11)

The following command retrieves the Intel flex filters data.

|         | Bits                          |       |                         |       |
|---------|-------------------------------|-------|-------------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                   | 07:00 |
| 00...15 | NC-SI Header                  |       |                         |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                         |       |
| 20...22 | 0x03                          | 0x11  | Filter Data Group 0...4 |       |

The Filter Data Group parameter defines which bytes of the Flex filter are returned by this command:

**Table 10-39 Filter Data Group**

| Code | Bytes Returned |
|------|----------------|
| 0x0  | bytes 0-29     |
| 0x1  | bytes 30-59    |
| 0x2  | bytes 60-89    |
| 0x3  | bytes 90-119   |
| 0x4  | bytes 120-127  |

### 10.6.3.6.8 Get Intel Filters — Flex Filter 0 Data Response (Intel Command 0x03, Filter Parameter 0x11)

|         | Bits          |       |             |       |
|---------|---------------|-------|-------------|-------|
| Bytes   | 31:24         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header  |       |             |       |
| 16...19 | Response Code |       | Reason Code |       |

|         |                               |               |                     |               |
|---------|-------------------------------|---------------|---------------------|---------------|
| 20...23 | Manufacturer ID (Intel 0x157) |               |                     |               |
| 24...   | 0x03                          | 0x11          | Filter Group Number | Filter Data 1 |
|         | ...                           | Filter Data N |                     |               |

#### 10.6.3.6.9 Get Intel Filters — Packet Addition Decision Filter Command (Intel Command 0x03, Filter Parameter 0x61)

**Note:** This command is kept and supported for legacy reasons, however it is recommended to use the Get Intel Filters - Packet Addition Extended Decision Filter Command (Intel Command 0x03, Filter parameter 0x68 - [Section 10.6.3.6.19](#)) instead

|         | Bits                          |       |                       |       |
|---------|-------------------------------|-------|-----------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                 | 07:00 |
| 00...15 | NC-SI Header                  |       |                       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                       |       |
| 20...21 | 0x03                          | 0x61  | Decision filter index |       |

Filter index range: 0x0...0x4.

#### 10.6.3.6.10 Get Intel Filters — Packet Addition Decision Filter Response (Intel Command 0x03, Filter Parameter 0x61)

|         | Bits                          |       |                       |       |
|---------|-------------------------------|-------|-----------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                 | 07:00 |
| 00...15 | NC-SI Header                  |       |                       |       |
| 16...19 | Response Code                 |       | Reason Code           |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                       |       |
| 24...27 | 0x03                          | 0x61  | Decision Filter (MSB) |       |
| 28...29 | Decision Filter (LSB)         |       |                       |       |

The Decision filter structure returned is described in [Table 10-37](#).

If the Decision filter index is bigger than 4, a command failed Response Code is returned with no reason.

#### 10.6.3.6.11 Get Intel Filters — Flex TCP/UDP Port Filter Command (Intel Command 0x03, Filter Parameter 0x63)

|         | Bits                          |       |                      |       |
|---------|-------------------------------|-------|----------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                | 07:00 |
| 00...15 | NC-SI Header                  |       |                      |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                      |       |
| 20...22 | 0x03                          | 0x63  | TCP/UDP Filter Index |       |

Filter index range: 0x0...0x2.

#### 10.6.3.6.12 Get Intel Filters — Flex TCP/UDP Port Filter Response (Intel Command 0x03, Filter Parameter 0x63)

|         | Bits                          |       |                      |                  |
|---------|-------------------------------|-------|----------------------|------------------|
| Bytes   | 31:24                         | 23:16 | 15:08                | 07:00            |
| 00...15 | NC-SI Header                  |       |                      |                  |
| 16...19 | Response Code                 |       | Reason Code          |                  |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                      |                  |
| 24...27 | 0x03                          | 0x63  | TCP/UDP Filter Index | TCP/UDP Port (1) |
| 28      | TCP/UDP Port (0)              |       |                      |                  |

If the TCP/UDP Filter Index is bigger than 2, a command failed Response Code is returned with no reason

#### 10.6.3.6.13 Get Intel Filters — IPv4 Filter Command (Intel Command 0x03, Filter Parameter 0x64)

|         | Bits                          |         |                   |         |
|---------|-------------------------------|---------|-------------------|---------|
| Bytes   | 31...24                       | 23...16 | 15...08           | 07...00 |
| 00...15 | NC-SI Header                  |         |                   |         |
| 16...19 | Manufacturer ID (Intel 0x157) |         |                   |         |
| 20...22 | 0x03                          | 0x64    | IPv4 Filter Index |         |

**Note:** The filters index range can vary according to the IPv4/IPv6 mode setting in the Filters Control command.

IPv4 Mode: Filter index range: 0x0...0x3.

IPv6 Mode: This command should not be used in IPv6 mode.

#### 10.6.3.6.14 Get Intel Filters — IPv4 Filter Response (Intel Command 0x03, Filter Parameter 0x64)

|         | Bits                          |       |                   |                  |
|---------|-------------------------------|-------|-------------------|------------------|
| Bytes   | 31:24                         | 23:16 | 15:08             | 07:00            |
| 00...15 | NC-SI Header                  |       |                   |                  |
| 16...19 | Response Code                 |       | Reason Code       |                  |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                   |                  |
| 24...27 | 0x03                          | 0x64  | IPv4 Filter Index | IPv4 Address (3) |
| 28...29 | IPv4 Address (2-0)            |       |                   |                  |

### 10.6.3.6.15 Get Intel Filters — IPv6 Filter Command (Intel Command 0x03, Filter Parameter 0x65)

|         | Bits                          |       |                   |       |
|---------|-------------------------------|-------|-------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08             | 07:00 |
| 00...15 | NC-SI Header                  |       |                   |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                   |       |
| 20...22 | 0x03                          | 0x65  | IPv6 Filter Index |       |

**Note:** The filters index range can vary according to the IPv4/IPv6 mode setting in the Filters Control command

IPv4 Mode: Filter index range: 0x0...0x2.

IPv6 Mode: Filter index range: 0x0...0x3.

### 10.6.3.6.16 Get Intel Filters — IPv6 Filter Response (Intel Command 0x03, Filter parameter 0x65)

|         | Bits                          |       |                            |                             |
|---------|-------------------------------|-------|----------------------------|-----------------------------|
| Bytes   | 31:24                         | 23:16 | 15:08                      | 07:00                       |
| 00...15 | NC-SI Header                  |       |                            |                             |
| 16...19 | Response Code                 |       | Reason Code                |                             |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                            |                             |
| 24...27 | 0x03                          | 0x65  | IPv6 Filter Index          | IPv6 Address (MSB, Byte 16) |
| 28...31 | ...                           | ...   | ...                        | ...                         |
| 32...35 | ...                           | ...   | ...                        | ...                         |
| 36...39 | ...                           | ...   | ...                        | ...                         |
| 40...42 | ...                           | ...   | IPv6 Address (LSB, Byte 0) |                             |

If the IPv6 Filter Index is bigger than 3, a command failed Response Code is returned with no reason.

### 10.6.3.6.17 Get Intel Filters - EtherType Filter Command (Intel Command 0x03, Filter parameter 0x67)

|         | Bits                          |       |                        |       |
|---------|-------------------------------|-------|------------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                  | 07:00 |
| 00...15 | NC-SI Header                  |       |                        |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                        |       |
| 20...22 | 0x03                          | 0x67  | EtherType Filter Index |       |

Valid indices: 0...3

#### 10.6.3.6.18 Get Intel Filters - EtherType Filter Response (Intel Command 0x03, Filter parameter 0x67)

|         | Bits                          |       |                        |                      |
|---------|-------------------------------|-------|------------------------|----------------------|
| Bytes   | 31:24                         | 23:16 | 15:08                  | 07:00                |
| 00...15 | NC-SI Header                  |       |                        |                      |
| 16...19 | Response Code                 |       | Reason Code            |                      |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                        |                      |
| 24...27 | 0x03                          | 0x67  | EtherType Filter Index | EtherType Filter MSB |
| 28...30 | ..                            | ..    | EtherType Filter LSB   |                      |

If the Ethertype filter Index is larger than 3, a command failed Response Code is returned with no reason.

#### 10.6.3.6.19 Get Intel Filters – Packet Addition Extended Decision Filter Command (Intel Command 0x03, Filter parameter 0x68)

This command allows the BMC to retrieve the Extended Decision Filter.

|         | Bits                          |       |                                |       |
|---------|-------------------------------|-------|--------------------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                          | 07:00 |
| 00...15 | NC-SI Header                  |       |                                |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                                |       |
| 20...22 | 0x03                          | 0x68  | Extended Decision Filter Index |       |

#### 10.6.3.6.20 Get Intel Filters – Packet Addition Extended Decision Filter Response (Intel Command 0x03, Filter parameter 0x68)

|         | Bits                          |       |                       |                       |
|---------|-------------------------------|-------|-----------------------|-----------------------|
| Bytes   | 31:24                         | 23:16 | 15:08                 | 07:00                 |
| 00...15 | NC-SI Header                  |       |                       |                       |
| 16...19 | Response Code                 |       | Reason Code           |                       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                       |                       |
| 24...27 | 0x03                          | 0x68  | Decision Filter Index | Decision Filter 1 MSB |
| 28...31 | ..                            | ..    | Decision Filter 1 LSB | Decision Filter 0 MSB |
| 32...34 | ..                            | ..    | Decision Filter 0 LSB |                       |

Where Decision Filter 0 & Decision Filter 1 have the structure as detailed in the respective “Set” commands.

If the Extended Decision Filter Index is bigger than 4, a command failed Response Code is returned with no reason.

### 10.6.3.7 Set Intel Packet Reduction Filters Formats

**Note:** The non extended commands (Section 10.6.3.7.3 to Section 10.6.3.8.8) are kept and supported for legacy reasons, however it is recommended to use the extended commands (Section 10.6.3.7.9 to Section 10.6.3.7.14) instead

#### 10.6.3.7.1 Set Intel Packet Reduction Filters Command (Intel Command 0x04)

|         | Bits                          |                        |                          |       |
|---------|-------------------------------|------------------------|--------------------------|-------|
| Bytes   | 31:24                         | 23:16                  | 15:08                    | 07:00 |
| 00...15 | NC-SI Header                  |                        |                          |       |
| 16...19 | Manufacturer ID (Intel 0x157) |                        |                          |       |
| 20...23 | 0x04                          | Packet Reduction Index | Packet Reduction Data... |       |

#### 10.6.3.7.2 Set Intel Packet Reduction Filters Response (Intel Command 0x04)

|         | Bits                          |                        |                      |         |
|---------|-------------------------------|------------------------|----------------------|---------|
| Bytes   | 31...24                       | 23...16                | 15...08              | 07...00 |
| 00...15 | NC-SI Header                  |                        |                      |         |
| 16...19 | Response Code                 |                        | Reason Code          |         |
| 20...23 | Manufacturer ID (Intel 0x157) |                        |                      |         |
| 24...   | 0x04                          | Packet Reduction Index | Optional Return Data |         |

The *Packet Reduction* Data field has the following structure:

**Table 10-40 Packet Reduction field description**

| Bit # | Name               | Description                                                                         |
|-------|--------------------|-------------------------------------------------------------------------------------|
| 12:0  | Reserved           | Reserved                                                                            |
| 16:13 | IPv4 Address (AND) | If set, packets must match IPv4 filter 0 to 3 respectively                          |
| 20:17 | IPv6 Address (AND) | If set, packets must match IPv6 filter 0 to 3 respectively                          |
| 27:21 | Reserved           | Reserved                                                                            |
| 28    | ARP Response (OR)  | If set, packets can pass if match the ARP response filter or a different OR filter. |
| 29    | Reserved           | Reserved                                                                            |
| 30    | Port 0x298         | If set, packets can pass if match a fixed TCP/UDP port 0x298 filter.                |
| 31    | Port 0x26F         | If set, packets can pass if match a fixed TCP/UDP port 0x26F filter.                |

**Table 10-41 Extended Packet Reduction field description**

| Bit # | Name                 | Description                                                                 |
|-------|----------------------|-----------------------------------------------------------------------------|
| 3:0   | Ethertype 0 -3 (AND) | If set, packets must match the Ethertype filter 0 to 3 respectively.        |
| 7:4   | Reserved             | Reserved                                                                    |
| 11:8  | Ethertype 0-3 (OR)   | If set, packets can pass if match the Ethertype filter 0 to 3 respectively. |
| 15:12 | Reserved             | Reserved                                                                    |
| 16    | Flex port 0 (OR)     | If set, packets can pass if match the TCP/UDP Port filter 0                 |
| 17    | Flex port 1 (OR)     | If set, packets can pass if match the TCP/UDP Port filter 1                 |
| 18    | Flex port 2 (OR)     | If set, packets can pass if match the TCP/UDP Port filter 2                 |
| 23:19 | Reserved             |                                                                             |
| 24    | Flex TCO (OR)        | If set, packets can pass if match the Flex 128 TCO filter                   |
| 31:25 | Reserved             |                                                                             |

The filtering is divided into two decisions:

- Bit 20:13 in [Table 10-40](#) and Bits 3:2 in [Table 10-41](#) works in an AND manner; it must be true in order for a packet to pass (if was set).

Bits 28 in [Table 10-40](#) and Bits 24:10 in [Table 10-41](#) work in an OR manner; at least one of them must be true for a packet to pass (if any were set).

### 10.6.3.7.3 Set Unicast Packet Reduction Command (Intel Command 0x04, Reduction Filter Index 0x00)

This command causes the NC to filter packets that have passed due to the unicast filter (MAC address filters, as specified in the DMTF NC-SI). Note that unicast filtering might be affected by other filters, as specified in the DMTF NC-SI.

The filtering of these packets are done such that the BMC might add a logical condition that a packet must match, or it must be discarded.

**Note:** Packets that might have been blocked can still pass due to other decision filters.

In order to disable unicast packet reduction, the BMC should set all reduction filters to 0b. Following such a setting the NC must forward, to the BMC, all packets that have passed the unicast filters (MAC address filtering) as specified in the DMTF NC-SI.

The *Unicast Packet Reduction* field structure is described in [Table 10-40](#).

| Bytes   | Bits                           |       |                                |       |
|---------|--------------------------------|-------|--------------------------------|-------|
|         | 31:24                          | 23:16 | 15:08                          | 07:00 |
| 00...15 | NC-SI Header                   |       |                                |       |
| 16...19 | Manufacturer ID (Intel 0x157)  |       |                                |       |
| 20...23 | 0x04                           | 0x00  | Unicast Packet Reduction (3-2) |       |
| 24...25 | Unicast Packet Reduction (1-0) |       |                                |       |

### 10.6.3.7.4 Set Unicast Packet Reduction Response (Intel Command 0x04, Reduction Filter Index 0x00)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x04                          | 0x00  |             |       |

#### 10.6.3.7.5 Set Multicast Packet Reduction Command (Intel Command 0x04, Reduction Filter Index 0x01)

This command causes the NC to filter packets that have passed due to the multicast filter (MAC address filters, as specified in the DMTF NC-SI).

The filtering of these packets are done such that the BMC might add a logical condition that a packet must match, or it must be discarded.

**Note:** Packets that might have been blocked can still pass due to other decision filters.

In order to disable multicast packet reduction, the BMC should set all reduction filters to 0b. Following such a setting, the NC must forward, to the BMC, all packets that have passed the multicast filters (global multicast filtering) as specified in the DMTF NC-SI.

The *Multicast Packet Reduction* field structure is described in [Table 10-40](#).

|         | Bits                             |       |                                  |       |
|---------|----------------------------------|-------|----------------------------------|-------|
| Bytes   | 31:24                            | 23:16 | 15:08                            | 07:00 |
| 00...15 | NC-SI Header                     |       |                                  |       |
| 16...19 | Manufacturer ID (Intel 0x157)    |       |                                  |       |
| 20...23 | 0x04                             | 0x01  | Multicast Packet Reduction (3-2) |       |
| 24...25 | Multicast Packet Reduction (1-0) |       |                                  |       |

#### 10.6.3.7.6 Set Multicast Packet Reduction Response (Intel Command 0x04, Reduction Filter Index 0x01)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x04                          | 0x01  |             |       |

#### 10.6.3.7.7 Set Broadcast Packet Reduction Command (Intel Command 0x04, Reduction Filter Index 0x02)

This command causes the NC to filter packets that have passed due to the broadcast filter (MAC address filters, as specified in the DMTF NC-SI).

The filtering of these packets are done such that the BMC might add a logical condition that a packet must match, or it must be discarded.

**Note:** Packets that might have been blocked can still pass due to other decision filters.

In order to disable broadcast packet reduction, the BMC should set all reduction filters to 0b. Following such a setting, the NC must forward, to the BMC, all packets that have passed the broadcast filters as specified in the DMTF NC-SI.

The *Broadcast Packet Reduction* field structure is described in [Table 10-40](#).

|         | Bits                             |       |                                  |       |
|---------|----------------------------------|-------|----------------------------------|-------|
| Bytes   | 31:24                            | 23:16 | 15:08                            | 07:00 |
| 00...15 | NC-SI Header                     |       |                                  |       |
| 16...19 | Manufacturer ID (Intel 0x157)    |       |                                  |       |
| 20...23 | 0x04                             | 0x02  | Broadcast Packet Reduction (3-2) |       |
| 24...25 | Broadcast Packet Reduction (1-0) |       |                                  |       |

#### 10.6.3.7.8 Set Broadcast Packet Reduction Response (Intel Command 0x08)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x04                          | 0x02  |             |       |

#### 10.6.3.7.9 Set Unicast Extended Packet Reduction Command (Intel Command 0x04, Reduction Filter Index 0x10)

In “Set Intel Reduction Filters” add another parameter “Unicast Extended Packet Reduction (Intel Command 0x04, Filter parameter 0x10)” such that the byte count is 0xE. The command shall have the following format:

|        | Bits                          |       |       |       |
|--------|-------------------------------|-------|-------|-------|
| Bytes  | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00..15 | NC-SI Header                  |       |       |       |
| 16..19 | Manufacturer ID (Intel 0x157) |       |       |       |

|        |      |                                       |                                       |    |
|--------|------|---------------------------------------|---------------------------------------|----|
| 20..23 | 0x04 | 0x10                                  | Extended Unicast Reduction Filter MSB | .. |
| 24..27 | ..   | Extended Unicast Reduction Filter LSB | Unicast Reduction Filter MSB          | .. |
| 28..29 | ..   | Unicast Reduction Filter LSB          |                                       |    |

The command shall overwrite any previously stored value.

**Note:** See [Table 10-40](#) and [Table 10-41](#) for description of the Unicast Extended Packet Reduction format.

#### 10.6.3.7.10 Set Unicast Extended Packet Reduction Response (Intel Command 0x04, Reduction Filter Index 0x10)

|        | Bits                          |       |             |       |
|--------|-------------------------------|-------|-------------|-------|
| Bytes  | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00..15 | NC-SI Header                  |       |             |       |
| 16..19 | Response Code                 |       | Reason Code |       |

| 24..25 | 0x04                          | 0x10  |             |       |

#### 10.6.3.7.11 Set Multicast Extended Packet Reduction Command (Intel Command 0x04, Reduction Filter Index 0x11)

| Bytes  | Bits                          |                                         |                                         |       |
|--------|-------------------------------|-----------------------------------------|-----------------------------------------|-------|
|        | 31:24                         | 23:16                                   | 15:08                                   | 07:00 |
| 00..15 | NC-SI Header                  |                                         |                                         |       |
| 16..19 | Manufacturer ID (Intel 0x157) |                                         |                                         |       |
| 20..23 | 0x04                          | 0x11                                    | Extended Multicast Reduction Filter MSB | ..    |
| 24..27 | ..                            | Extended Multicast Reduction Filter LSB | Multicast Reduction Filter MSB          | ..    |
| 28..29 | ..                            | Multicast Reduction Filter LSB          |                                         |       |

**Note:** See [Table 10-40](#) and [Table 10-41](#) for description of the Multicast Extended Packet Reduction format.

The command shall overwrite any previously stored value.

#### 10.6.3.7.12 Set Multicast Extended Packet Reduction Response (Intel Command 0x04, Reduction Filter Index 0x11)

|        | Bits                          |       |             |       |
|--------|-------------------------------|-------|-------------|-------|
| Bytes  | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00..15 | NC-SI Header                  |       |             |       |
| 16..19 | Response Code                 |       | Reason Code |       |
| 20..23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24..25 | 0x04                          | 0x11  |             |       |

### 10.6.3.7.13 Set Broadcast Extended Packet Reduction Command (Intel Command 0x04, Reduction Filter Index 0x12)

|        | Bits                          |                                         |                                         |       |
|--------|-------------------------------|-----------------------------------------|-----------------------------------------|-------|
| Bytes  | 31:24                         | 23:16                                   | 15:08                                   | 07:00 |
| 00..15 | NC-SI Header                  |                                         |                                         |       |
| 16..19 | Manufacturer ID (Intel 0x157) |                                         |                                         |       |
| 20..23 | 0x04                          | 0x12                                    | Extended Broadcast Reduction Filter MSB | ..    |
| 24..27 | ..                            | Extended Broadcast Reduction Filter LSB | Broadcast Reduction Filter MSB          | ..    |
| 28..29 | ..                            | Broadcast Reduction Filter LSB          |                                         |       |

**Note:** See [Table 10-40](#) and [Table 10-41](#) for description of the Broadcast Extended Packet Reduction format.

The command shall overwrite any previously stored value.

### 10.6.3.7.14 Set Broadcast Extended Packet Reduction Response (Intel Command 0x04, Reduction Filter Index 0x12)

|        | Bits                          |       |             |       |
|--------|-------------------------------|-------|-------------|-------|
| Bytes  | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00..15 | NC-SI Header                  |       |             |       |
| 16..19 | Response Code                 |       | Reason Code |       |
| 20..23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24..25 | 0x04                          | 0x12  |             |       |

## 10.6.3.8 Get Intel Packet Reduction Filters Formats

**Note:** The non extended commands ([Section 10.6.3.8.3](#) to [Section 10.6.3.8.8](#)) are kept and supported for legacy reasons, however it is recommended to use the extended commands ([Section 10.6.3.8.9](#) to [Section 10.6.3.8.14](#)) instead

### 10.6.3.8.1 Get Intel Packet Reduction Filters Command (Intel Command 0x05)

|         | Bits                          |                        |       |       |
|---------|-------------------------------|------------------------|-------|-------|
| Bytes   | 31:24                         | 23:16                  | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |                        |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |                        |       |       |
| 20...21 | 0x05                          | Reduction Filter Index |       |       |

### 10.6.3.8.2 Get Intel Packet Reduction Filters Response (Intel Command 0x05)

|         | Bits                          |                        |             |       |
|---------|-------------------------------|------------------------|-------------|-------|
| Bytes   | 31:24                         | 23:16                  | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |                        |             |       |
| 16...19 | Response Code                 |                        | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |                        |             |       |
| 24...   | 0x05                          | Reduction Filter Index | Return Data |       |

**Note:** See Table 10-40 and Table 10-41 for description of the Return Data format.

### 10.6.3.8.3 Get Unicast Packet Reduction Command (Intel Command 0x05, Reduction Filter Index 0x00)

This command causes the NC to disable any packet reductions for unicast address filtering.

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x05                          | 0x00  |       |       |

### 10.6.3.8.4 Get Unicast Packet Reduction Response (Intel Command 0x05, Reduction Filter Index 0x00)

|         | Bits          |       |             |       |
|---------|---------------|-------|-------------|-------|
| Bytes   | 31:24         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header  |       |             |       |
| 16...19 | Response Code |       | Reason Code |       |

|         |                                |      |                                |
|---------|--------------------------------|------|--------------------------------|
| 20...23 | Manufacturer ID (Intel 0x157)  |      |                                |
| 24...27 | 0x05                           | 0x00 | Unicast Packet Reduction (MSB) |
| 28...29 | Unicast Packet Reduction (LSB) |      |                                |

#### 10.6.3.8.5 Get Multicast Packet Reduction Command (Intel Command 0x05, Reduction Filter Index 0x01)

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x05                          | 0x01  |       |       |

#### 10.6.3.8.6 Get Multicast Packet Reduction Response (Intel Command 0x05, Reduction Filter Index 0x01)

|         | Bits                             |       |                                  |       |
|---------|----------------------------------|-------|----------------------------------|-------|
| Bytes   | 31:24                            | 23:16 | 15:08                            | 07:00 |
| 00...15 | NC-SI Header                     |       |                                  |       |
| 16...19 | Response Code                    |       | Reason Code                      |       |
| 20...23 | Manufacturer ID (Intel 0x157)    |       |                                  |       |
| 24...27 | 0x05                             | 0x01  | Multicast Packet Reduction (MSB) |       |
| 28...29 | Multicast Packet Reduction (LSB) |       |                                  |       |

#### 10.6.3.8.7 Get Broadcast Packet Reduction Command (Intel Command 0x05, Reduction Filter Index 0x02)

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x05                          | 0x02  |       |       |

#### 10.6.3.8.8 Get Broadcast Packet Reduction Response (Intel Command 0x05, Reduction Filter Index 0x02)

|         | Bits                             |       |                                  |       |
|---------|----------------------------------|-------|----------------------------------|-------|
| Bytes   | 31:24                            | 23:16 | 15:08                            | 07:00 |
| 00...15 | NC-SI Header                     |       |                                  |       |
| 16...19 | Response Code                    |       | Reason Code                      |       |
| 20...23 | Manufacturer ID (Intel 0x157)    |       |                                  |       |
| 24...27 | 0x05                             | 0x02  | Broadcast Packet Reduction (MSB) |       |
| 28...29 | Broadcast Packet Reduction (LSB) |       |                                  |       |

#### 10.6.3.8.9 Get Unicast Extended Packet Reduction Command (Intel Command 0x05, Reduction Filter Index 0x10)

\

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x05                          | 0x10  |       |       |

#### 10.6.3.8.10 Get Unicast Extended Packet Reduction Response (Intel Command 0x05, Reduction Filter Index 0x10)

|         | Bits                                    |       |                                         |       |
|---------|-----------------------------------------|-------|-----------------------------------------|-------|
| Bytes   | 31:24                                   | 23:16 | 15:08                                   | 07:00 |
| 00...15 | NC-SI Header                            |       |                                         |       |
| 16...19 | Response Code                           |       | Reason Code                             |       |
| 20...23 | Manufacturer ID (Intel 0x157)           |       |                                         |       |
| 24...27 | 0x05                                    | 0x10  | Extended Unicast Packet Reduction (MSB) |       |
| 28...31 | Extended Unicast Packet Reduction (LSB) |       | Unicast Packet Reduction (MSB)          |       |
| 32...33 | Unicast Packet Reduction (LSB)          |       |                                         |       |

#### 10.6.3.8.11 Get Multicast Extended Packet Reduction Command (Intel Command 0x05, Reduction Filter Index 0x11)

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x05                          | 0x11  |       |       |

### 10.6.3.8.12 Get Multicast Extended Packet Reduction Response (Intel Command 0x05, Reduction Filter Index 0x11)

|         | Bits                                      |       |                                           |       |
|---------|-------------------------------------------|-------|-------------------------------------------|-------|
| Bytes   | 31:24                                     | 23:16 | 15:08                                     | 07:00 |

## 10.6.3.9 System MAC Address

### 10.6.3.9.1 Get System MAC Address Command (Intel Command 0x06)

In order to support a system configuration that requires the NC to hold the MAC address for the BMC (such as shared MAC address mode), the following command is provided to enable the BMC to query the NC for a valid MAC address.

The NC must return the system MAC addresses. The BMC should use the returned MAC addressing as a shared MAC address by setting it using the Set MAC Address command as defined in NC-SI 1.0.

It is also recommended that the BMC use packet reduction and Manageability-to-Host command to set the proper filtering method.

|         | Bits                          |       |       |       |

| 20...23 | Manufacturer ID (Intel 0x157) |             |             |       |
| 24...27 | 0x06                          | MAC Address |             |       |
| 28...30 | MAC Address                   |             |             |       |

#### 10.6.3.10 Set Intel Management Control Formats

##### 10.6.3.10.1 Set Intel Management Control Command (Intel Command 0x20)

|         | Bits                          |       |                            |       |
|---------|-------------------------------|-------|----------------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                      | 07:00 |
| 00...15 | NC-SI Header                  |       |                            |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |                            |       |
| 20...22 | 0x20                          | 0x00  | Intel Management Control 1 |       |

Where Intel Management Control 1 is as follows:

| Bit # | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | 0b            | Enable Critical Session Mode (Keep PHY Link Up and Veto Bit)<br>0b — Disabled<br>1b — Enabled<br>When critical session mode is enabled, the following behaviors are disabled: <ul style="list-style-type: none"> <li>The PHY is not reset on PE_RST# and PCIe resets (in-band and link drop). Other reset events are not affected — Internal_Power_On_Reset, device disable, Force TCO, and PHY reset by software.</li> <li>The PHY does not change its power state. As a result link speed does not change.</li> <li>The device does not initiate configuration of the PHY to avoid losing link.</li> </ul> |
| 1...7 | 0x0           | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### 10.6.3.10.2 Set Intel Management Control Response (Intel Command 0x20)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x20                          | 0x00  |             |       |

## 10.6.3.11 Get Intel Management Control Formats

### 10.6.3.11.1 Get Intel Management Control Command (Intel Command 0x21)

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x21                          | 0x00  |       |       |

Where Intel Management Control 1 is as described in [Section 10.6.3.10.2](#).

### 10.6.3.11.2 Get Intel Management Control Response (Intel Command 0x21)

|         | Bits                          |       |                            |       |
|---------|-------------------------------|-------|----------------------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08                      | 07:00 |
| 00...15 | NC-SI Header                  |       |                            |       |
| 16...19 | Response Code                 |       | Reason Code                |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |                            |       |
| 24...26 | 0x21                          | 0x00  | Intel Management Control 1 |       |

### 10.6.3.12 TCO Reset

Depending on the bit set in the TCO mode field this command will cause the I350 to perform either:

1. TCO Reset, if Force TCO reset is enabled in the EEPROM (see [Section 6.3.7](#)). The Force TCO reset will clear the data-path (RX/TX) of the I350 to enable the BMC to transmit/receive packets through the I350.
  - If the BMC has detected that the OS is hung and has blocked the RX/TX path The Force TCO reset will clear the data-path (RX/TX) of the Network Controller to enable the BMC to transmit/receive packets through the Network Controller.
  - When this command is issued to a channel in a package, it applies only to the specific channel.
  - After successfully performing the command the Network Controller will consider Force TCO command as an indication that the OS is hung and will clear the DRV\_LOAD flag (disable the driver). If TCO reset is disabled in EEPROM the I350 clears the CTRL\_EXT.DRV\_LOAD bit but does not reset the data-path and notifies BMC on successful completion.
  - Following TCO reset management sets *MANC.TCO\_RESET* to 1.
2. TCO isolate, if TCO isolate is enabled in the EEPROM (See [Section 6.3.7.3](#)). The TCO Isolate command will disable PCIe write operations to the LAN port.
  - If TCO Isolate is disabled in EEPROM the I350 does not execute the command but sends a response to the BMC with successful completion.
  - Following TCO Isolate management sets *MANC.TCO\_Isolate* to 1.
3. Firmware Reset. This command will cause re-initialization of all the manageability functions and re-load of manageability related EEPROM words (e.g. Firmware patch code).
  - When the BMC has loaded new management related EEPROM image (e.g. Firmware patch) the Firmware Reset command will load management related EEPROM information without need to power down the system.
  - This command is issued to the package and affects all channels. After the Firmware reset the FW Semaphore register (FWSM) is re-initialized.

**Notes:** Force TCO reset and TCO Isolate will affect only the channel (port) that the command was issued to.

Following firmware reset, BMC will need to re-initialize all ports.

#### 10.6.3.12.1 Perform Intel TCO Reset Command (Intel Command 0x22)

|         | Bits                          |          |       |       |
|---------|-------------------------------|----------|-------|-------|
| Bytes   | 31:24                         | 23:16    | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |          |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |          |       |       |
| 20      | 0x22                          | TCO Mode |       |       |

Where TCO Mode is:

| Field                       | Bit(s) | Description                                                                                                                                                                                                                                            |
|-----------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DO_TCO_RST                  | 0      | Perform TCO Reset.<br>0b: Do nothing.<br>1b: Perform TCO reset.                                                                                                                                                                                        |
| DO_TCO_ISOLATE <sup>1</sup> | 1      | Do TCO Isolate<br>0b = Enable PCIe write access to LAN port.<br>1b = Isolate Host PCIe write operation to the port<br>Note: Should be used for debug only.<br>Note: When Isolate is set, the OS2BMC flow is disabled also.                             |
| RESET_MGMT                  | 2      | Reset manageability; re-load manageability EEPROM words.<br>0b = Do nothing<br>1b = Issue firmware reset to manageability<br>Setting this bit generates a one-time firmware reset. Following the reset, management related data from EEPROM is loaded. |
| Reserved                    | 7:3    | Reserved (set to 0x00).                                                                                                                                                                                                                                |

**Note:** For compatibility, the TCO reset command without the TCO Mode parameter is accepted (TCO reset is performed).

1. TCO Isolate Host Write operation enabled in EEPROM.

### 10.6.3.12.2 Perform Intel TCO Reset Response (Intel Command 0x22)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...26 | 0x22                          |       |             |       |

### 10.6.3.13 Checksum Offloading

This command enables the checksum offloading filters in the NC.

When enabled, these filters block any packets that did not pass IP, UDP and TCP checksums from being forwarded to the BMC.

### 10.6.3.13.1 Enable Checksum Offloading Command (Intel Command 0x23)

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20      | 0x23                          |       |       |       |

### 10.6.3.13.2 Enable Checksum Offloading Response (Intel Command 0x23)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...26 | 0x23                          |       |             |       |

### 10.6.3.13.3 Disable Checksum Offloading Command (Intel Command 0x24)

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20      | 0x24                          |       |       |       |

### 10.6.3.13.4 Disable Checksum Offloading Response (Intel Command 0x24)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...26 | 0x24                          |       |             |       |

### 10.6.3.14 OS 2 BMC Configuration

These commands control enabling of the OS 2 BMC flow.

**Note:** If OS2BMC is disabled these commands will fail with response code 0x0001 (command failed) and reason code 0x0000.

#### 10.6.3.14.1 EnableOS2BMC Flow Command (Intel Command 0x40, Index 0x1)

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x40                          | 0x01  |       |       |

#### 10.6.3.14.2 EnableOS2BMC Flow Response (Intel Command 0x40, Index 0x1)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x40                          | 0x01  |             |       |

#### 10.6.3.14.3 Enable Network to BMC Flow Command (Intel Command 0x40, Index 0x2)

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x40                          | 0x02  |       |       |

#### 10.6.3.14.4 Enable Network to BMC Flow Response (Intel Command 0x40, Index 0x2)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x40                          | 0x02  |             |       |

#### 10.6.3.14.5 Enable both Host and Network to BMC flows Command (Intel Command 0x40, Index 0x3)

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...21 | 0x40                          | 0x03  |       |       |

#### 10.6.3.14.6 Enable both Host and Network to BMC Flows Response (Intel Command 0x40, Index 0x3)

|         | Bits                          |       |             |       |
|---------|-------------------------------|-------|-------------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |       |             |       |
| 16...19 | Response Code                 |       | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |       |
| 24...25 | 0x40                          | 0x03  |             |       |

#### 10.6.3.14.7 Get OS2BMC parameters Command (Intel Command 0x41)

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20      | 0x41                          |       |       |       |

#### 10.6.3.14.8 Get OS2BMC parameters Response (Intel Command 0x41)

|         | Bits                          |        |             |       |
|---------|-------------------------------|--------|-------------|-------|
| Bytes   | 31:24                         | 23:16  | 15:08       | 07:00 |
| 00...15 | NC-SI Header                  |        |             |       |
| 16...19 | Response Code                 |        | Reason Code |       |
| 20...23 | Manufacturer ID (Intel 0x157) |        |             |       |
| 24...27 | 0x41                          | Status |             |       |

Where the Status byte partition is as follow:

**Table 10-42 Status byte description**

| Bits | Content                                                                                           |
|------|---------------------------------------------------------------------------------------------------|
| 1:0  | Reserved                                                                                          |
| 2    | Network to BMC status<br>0 = network 2 BMC flow is disabled<br>1 = network 2 BMC flow is enabled. |
| 3    | OS2BMC status<br>0 = OS 2 BMC flow is disabled<br>1 = OS 2 BMC flow is enabled.                   |
| 7:4  | Reserved.                                                                                         |

## 10.6.3.15 Inventory and Update System Parameters Commands

### 10.6.3.15.1 Get Controller Information Command (Intel Command 0x48, Index 0x1)

This command gather the controller identification information and return it back to the BMC.

|         | Bits                          |       |       |       |
|---------|-------------------------------|-------|-------|-------|
| Bytes   | 31:24                         | 23:16 | 15:08 | 07:00 |
| 00...15 | NC-SI Header                  |       |       |       |
| 16...19 | Manufacturer ID (Intel 0x157) |       |       |       |
| 20...23 | 0x48                          | 0x1   |       |       |

### 10.6.3.15.2 Get Controller information Response (Intel Command 0x48, Index 0x1)

|         | Bits                          |       |             |                             |
|---------|-------------------------------|-------|-------------|-----------------------------|
| Bytes   | 31:24                         | 23:16 | 15:08       | 07:00                       |
| 00...15 | NC-SI Header                  |       |             |                             |
| 16...19 | Response Code                 |       | Reason Code |                             |
| 20...23 | Manufacturer ID (Intel 0x157) |       |             |                             |
| 24...27 | 0x48                          | 0x01  | Reserved    | Number of Inventory entries |

|         | Bits                 |                          |                        |       |
|---------|----------------------|--------------------------|------------------------|-------|
| Bytes   | 31:24                | 23:16                    | 15:08                  | 07:00 |
| 28...31 | FW version Item 1ID  | FW version Item 1 length | FW version Item 1 Data |       |
| ...     | ....                 |                          |                        |       |
| ...     | FW version Item 2 ID | FW version Item 2 length | FW version Item 2 Data |       |
| ...     | ....                 |                          |                        |       |
| ...     | FW version Item n ID | FW version Item n length | FW version Item n Data |       |
| ...     | ....                 |                          |                        |       |

Where the possible inventory items are as described below. Note that not all the inventory items would be present in all the implementations of this command.

**Table 10-43 Controller Information Items**

| ID   | Length (in bytes) | Data                         | Notes                                                                                                                   | Available without driver? |
|------|-------------------|------------------------------|-------------------------------------------------------------------------------------------------------------------------|---------------------------|
| 0x0D | 2                 | NC-SI FW version             | Major.Minor                                                                                                             | Yes                       |
| 0x0E | 2                 | PXE FW version               | MajorVersion.MinorVersion.Build.                                                                                        | Yes                       |
| 0x0F | 2                 | iSCSI FW version             | MajorVersion.MinorVersion.Build.                                                                                        | Yes                       |
| 0x10 | 2                 | uEFI FW version              | MajorVersion.MinorVersion.Build.                                                                                        | Yes                       |
| 0x11 | 2                 | Loader FW Patch Version      | Major.Minor                                                                                                             | Yes                       |
| 0x12 | 2                 | Application FW Patch Version | Should reflect the version of the patch currently used by the FW and not the FW version of the patch stored in the NVM. | Yes                       |

### 10.6.3.16 Thermal Sensor Commands

**Note:** Most of the actions exposed here are available only when working with an internal PHY. There is no support for controlling of external PHY behaviors according to thermal sensor inputs.

**Note:** Thermal Sensor configuration can be done only through NC-SI channel 0.

#### 10.6.3.16.1 Get Thermal Sensor Commands (Intel Command 0x4C)

##### 10.6.3.16.1.1 Common Tables

The following tables are used in the various commands:

**Table 10-44 Actions word definition**

| Bit   | Action                                 | Notes                                                                                                                                         |
|-------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | Measure Only <sup>1</sup>              | Activate the thermal sensor, but no automatic action.                                                                                         |
| 1     | Notify BMC <sup>1</sup>                |                                                                                                                                               |
| 2     | Power off PHY                          |                                                                                                                                               |
| 3     | Power on PHY                           |                                                                                                                                               |
| 4     | Restore Speed                          | Restore regular speed. When used as "Active Action", should be set if there are no limitations on the speed setting.                          |
| 5     | Set speed to 10 Mbps Max               | These actions set a maximum on the speed and do not force a specific speed. The Set Link command should be used to set a specific link speed. |
| 6     | Set speed to 100 Mbps Max              |                                                                                                                                               |
| 7     | Set speed to 1 Gbps Max                |                                                                                                                                               |
| 8     | Set speed to 10 Gbps Max               |                                                                                                                                               |
| 9     | Indicate on SDP (set) <sup>1</sup>     |                                                                                                                                               |
| 10    | Indicate on SDP (clear) <sup>1</sup>   |                                                                                                                                               |
| 11    | HW autonomous algorithm                |                                                                                                                                               |
| 12    | Cancel all active actions <sup>1</sup> |                                                                                                                                               |
| 13    | Rearm Event <sup>1</sup>               |                                                                                                                                               |
| 31:14 | Reserved                               |                                                                                                                                               |

1. These bits are not relevant when reporting active actions. Values should be ignored.

**Table 10-45 Unit Types word definition**

| Value    | Unit Types     | Notes                                    |
|----------|----------------|------------------------------------------|
| 0x0      | Generic Number | No specific indication of measured value |
| 0x1      | Celsius        | Temperature                              |
| 0x2      | Volts          |                                          |
| 0x3      | rpm            | Speed                                    |
| 0x4-0xFF | Reserved       | Reserved.                                |

### 10.6.3.16.1.2 Threshold and Hysteresis

Each threshold event includes a direction. For example, a thermal event with a threshold of 100 C and an "up" direction is defined as the temperature crossing from less than 100 C to more than 100 C.

For each threshold an hysteresis may be defined. This hysteresis direction is opposite to the threshold direction. So if, for the previous example, an hysteresis of 10 C is defined, it will be activated when the temperature crosses from more than 90 C to less than 90 C.

The following figure describes the thresholds and hysteresis modes and the actions activated for each of them.

**Figure 10-9** Thresholds, hysteresis and actions.

### 10.6.3.16.2 Get Thermal Sensor Capabilities Command (Intel Command 0x4C, Index 0x0)

This command requests the thermal sensor capabilities supported by this device.

|         | Bits                          |         |         |         |
|---------|-------------------------------|---------|---------|---------|
| Bytes   | 31...24                       | 23...16 | 15...08 | 07...00 |
| 00...15 | NC-SI Header                  |         |         |         |
| 16...19 | Manufacturer ID (Intel 0x157) |         |         |         |
| 20...21 | 0x4C                          | 0x00    |         |         |

### 10.6.3.16.3 Get Thermal Sensor Capabilities Response (Intel Command 0x4c, Index 0x0)

|         | Bits                          |        |             |                |
|---------|-------------------------------|--------|-------------|----------------|
| Bytes   | 31..24                        | 23..16 | 15..08      | 07..00         |
| 00...15 | NC-SI Header                  |        |             |                |
| 16...19 | Response Code                 |        | Reason Code |                |
| 20...23 | Manufacturer ID (Intel 0x157) |        |             |                |
| 24...27 | 0x4C                          | 0x0    | Version     | Unit Types     |
| 28...31 | Number of Thresholds          |        | Accuracy    | Max hysteresis |
| 32...35 | M                             | B      | K1          | K2             |

|         |                                             |  |  |
|---------|---------------------------------------------|--|--|
| 36...39 | Available actions - "High going" thresholds |  |  |
| 40..43  | Available actions - "Low going" thresholds  |  |  |
| 44..47  | Available actions - "Immediate"             |  |  |
| 48      | TJunction Max                               |  |  |

- Version should always be 1.
- Unit Types = 1 - we report temperature in Celsius.
- Accuracy describes the accuracy of the reported measurements as follow:
  - 7:4: Max deviation of actual value above measurement in "unit types" = 5 C
  - 3:0: Max deviation of actual value below measurement in "unit types" = 5 C
- Max hysteresis - defines the max hysteresis value allowed in the implementation = 0xF - an hysteresis of up to 15 degrees is supported
- Number of thresholds describes the number of up and down thresholds as follow:
  - 15:12: Reserved
  - 11:8: Max Number of mixed thresholds = 0.
  - 7:4: Max number of up thresholds = 3
  - 3:0: Max number of down thresholds = 0
- Valid Actions "High going" thresholds - describes the actions that can be activated by the device as described in [Table 10-44](#) when an high going threshold is crossed. The I350 supports Do Nothing, Notify BMC, Power off PHY, Set speed to 10 Mbps, Set speed to 100 Mbps, Indicate on SDP (set), and Indicate on SDP (clear).
- Valid Actions "Low going" thresholds - describes the actions that can be activated by the device as described in [Table 10-44](#) when an low going threshold is crossed. The I350 supports Notify BMC, Power on PHY, Restore Speed, Indicate on SDP (set), and Indicate on SDP (clear).
- Valid Actions "Immediate" - describes the actions that can be activated by the device as described in [Table 10-44](#) using a "Perform Thermal Sensor Action" command. The I350 supports Measure only, Reset or Speed, Cancel all active actions and reset thermal sensor.
- M = 1; B = 0, K1 = K2 = 0 - The assumption is that the thermal sensor in the I350 is the readable value.

**Note:** This formula is compliant with the definition of section 36.3 "Sensor Reading Conversion Formula" in IPMI 2.0

- TjunctionMax - The maximal junction temperature supported (125 C).

#### 10.6.3.16.4 Get Thermal Sensor Configuration Command (Intel Command 0x4C, Index 0x1)

This command requests the thermal sensor configuration for threshold "Index".

|         | Bits                          |         |         |         |
|---------|-------------------------------|---------|---------|---------|
| Bytes   | 31...24                       | 23...16 | 15...08 | 07...00 |
| 00...15 | NC-SI Header                  |         |         |         |
| 16...19 | Manufacturer ID (Intel 0x157) |         |         |         |
| 20...22 | 0x4C                          | 0x01    | Index   |         |

**Note:** If Index points to a non valid threshold as described in the Get Thermal Sensor Capabilities Response, the command fails with an Invalid Parameter reason.

#### 10.6.3.16.5 Get Thermal Sensor Configuration Response (Intel Command 0x4c, Index 0x1)

|         | Bits                          |                            |             |               |
|---------|-------------------------------|----------------------------|-------------|---------------|
| Bytes   | 31..24                        | 23..16                     | 15..08      | 07..00        |
| 00...15 | NC-SI Header                  |                            |             |               |
| 16...19 | Response Code                 |                            | Reason Code |               |
| 20...23 | Manufacturer ID (Intel 0x157) |                            |             |               |
| 24...27 | 0x4C                          | 0x1                        | Index       | Threshold (1) |
| 28...31 | Threshold (0)                 | Actions "Going High" (3-1) |             |               |
| 32...35 | Actions "Going High" (0)      | Actions "Going Low" (3-1)  |             |               |
| 36...38 | Actions "Going Low" (0)       | Direction                  | Hysteresis  |               |

The threshold and the Hysteresis are measured in "unit types".

The "Actions Going High" field describes the actions to activate upon crossing of the threshold for "Going High" thresholds or when crossing the hysteresis for "Going Low" thresholds according to [Table 10-44](#).

The "Actions Going Low" field describes the actions to activate upon crossing of the threshold for "Going Low" thresholds or when crossing the hysteresis for "Going High" thresholds according to [Table 10-44](#).

Direction is encoded as follow:

- 0 = High Going
- 1 = Low Going

#### 10.6.3.16.6 Get Thermal Sensor Status Command (Intel Command 0x4C, Index 0x2)

This command requests the current status of the Thermal sensor.

|         | Bits                          |         |         |         |
|---------|-------------------------------|---------|---------|---------|
| Bytes   | 31...24                       | 23...16 | 15...08 | 07...00 |
| 00...15 | NC-SI Header                  |         |         |         |
| 16...19 | Manufacturer ID (Intel 0x157) |         |         |         |
| 20...21 | 0x4C                          | 0x02    |         |         |

#### 10.6.3.16.7 Get Thermal Sensor Status Response (Intel Command 0x4c, Index 0x2)

|         | Bits                          |         |                |         |
|---------|-------------------------------|---------|----------------|---------|
| Bytes   | 31...24                       | 23...16 | 15...08        | 07...00 |
| 00...15 | NC-SI Header                  |         |                |         |
| 16...19 | Response Code                 |         | Reason Code    |         |
| 20...23 | Manufacturer ID (Intel 0x157) |         |                |         |
| 24...27 | 0x4C                          | 0x2     | Measured Value |         |
| 28...31 | Active Actions                |         |                |         |
| 32...33 | Threshold cross events        |         |                |         |

Where “Threshold cross events” is a bitmap that describes which events were crossed since the last read of the status or since the activation of the thermal sensor (the latest of the two).

### 10.6.3.16.8 Set Thermal Sensor Commands (Intel Command, Index 0x4D)

#### 10.6.3.16.8.1 Set Thermal Sensor Configuration Command (Intel Command 0x4D, Index 0x1)

This command sets the thermal sensor configuration for threshold “Index”

The threshold and the Hysteresis are measured in “unit types”.

The “Actions Going High” field describes the actions to activate upon crossing of the threshold for “Going High” thresholds or when crossing the hysteresis for “Going Low” thresholds according to [Table 10-44](#).

The “Actions Going Low” field describes the actions to activate upon crossing of the threshold for “Going Low” thresholds or when crossing the hysteresis for “Going High” thresholds according to [Table 10-44](#).

Direction is encoded as follow:

- 0 = High Going
- 1 = Low Going

|         | Bits                          |         |                            |           |
|---------|-------------------------------|---------|----------------------------|-----------|
| Bytes   | 31...24                       | 23...16 | 15...08                    | 07...00   |
| 00...15 | NC-SI Header                  |         |                            |           |
| 16...19 | Manufacturer ID (Intel 0x157) |         |                            |           |
| 20...23 | 0x4D                          | 0x01    | Index                      | Direction |
| 24...27 | Threshold                     |         | Actions “Going High” (MSB) |           |
| 28...31 | Actions “Going High” (LSB)    |         | Actions “Going Low” (MSB)  |           |
| 32...34 | Actions “Going Low” (LSB)     |         | Hysteresis                 |           |

**Note:** If Index and Direction points to a non valid threshold as described in the Get Thermal Sensor Capabilities Response, the command fails with an Invalid Parameter reason.

If the requested action is not supported, the command fails with an Invalid Parameter reason. Actions set can not be contradictory - so for a given set of actions, the following combinations are invalid and will result in a command fails with an Invalid Parameter reason:

- Indicate on SDP (set) and Indicate on SDP (clear) both set,
- Power off PHY and Power up PHY both set.
- Increase and Reduce Speed both set.
- Both a maximal speed and a PHY power off action are requested.
- More than one maximal speed is requested.
- Do Nothing and another option are requested.
- HW independent algorithm and another option are requested.

#### 10.6.3.16.8.2 Set Thermal Sensor Configuration Response (Intel Command 0x4c, Index 0x1)

|         | Bits                          |         |             |         |
|---------|-------------------------------|---------|-------------|---------|
| Bytes   | 31...24                       | 23...16 | 15...08     | 07...00 |
| 00...15 | NC-SI Header                  |         |             |         |
| 16...19 | Response Code                 |         | Reason Code |         |
| 20...23 | Manufacturer ID (Intel 0x157) |         |             |         |
| 24...25 | 0x4D                          | 0x1     |             |         |

#### 10.6.3.16.8.3 Set Thermal Sensor Action Command (Intel Command 0x4D, Index 0x2)

This command executes actions immediately.

The "Actions" field describes the actions to activate according to [Table 10-44](#).

|         | Bits                          |         |               |         |
|---------|-------------------------------|---------|---------------|---------|
| Bytes   | 31...24                       | 23...16 | 15...08       | 07...00 |
| 00...15 | NC-SI Header                  |         |               |         |
| 16...19 | Manufacturer ID (Intel 0x157) |         |               |         |
| 20...23 | 0x4D                          | 0x02    | Actions (MSB) |         |
| 24...25 | Actions (LSB)                 |         |               |         |

**Note:** If one of the requested actions is not supported, the command fails with an Invalid Parameter reason.

**Note:** Actions set can not be contradictory - so the following combinations are invalid and will result in a command fails with an Invalid Parameter reason:

- Indicate on SDP (set) and Indicate on SDP (clear) both set,
- Power Down PHY and Power up PHY both set.
- Restore and one of the Reduce Speed both set.
- Both a maximal speed and a PHY power down action are requested.
- More than one maximal speed is requested.

- Do Nothing and another option are requested.
- HW independent algorithm and another option are requested.

#### 10.6.3.16.8.4 Set Thermal Sensor Configuration Response (Intel Command 0x4c, Index 0x1)

|         | Bits                          |         |             |         |
|---------|-------------------------------|---------|-------------|---------|
| Bytes   | 31...24                       | 23...16 | 15...08     | 07...00 |
| 00...15 | NC-SI Header                  |         |             |         |
| 16...19 | Response Code                 |         | Reason Code |         |
| 20...23 | Manufacturer ID (Intel 0x157) |         |             |         |
| 24...25 | 0x4D                          | 0x2     |             |         |

#### 10.6.3.16.9 Thermal Sensor AEN (Intel AEN 0x81)

The following is the AEN that may be sent by the NC following a Thermal Sensor event.

This AEN must be enabled using the NC-SI “AEN Enable” command, using bit 17 (0x20000) of the AEN Enable mask.

|         | Bits                 |         |                        |         |
|---------|----------------------|---------|------------------------|---------|
| Bytes   | 31...24              | 23...16 | 15...08                | 07...00 |
| 00...15 | NC-SI AEN Header     |         |                        |         |
| 20...23 | Reserved             |         |                        | 0x81    |
| 24...27 | Measured Value       |         | Active Actions (3-2)   |         |
| 28...31 | Active Actions (1-0) |         | Threshold cross events |         |

Where “Threshold cross events” is a bitmap that describes which events were crossed since the last read of the status, AEN emission or since the activation of the thermal sensor (the latest of the two).

## 10.6.4 Basic NC-SI Workflows

### 10.6.4.1 Package States

A NC package can be in one of the following two states:

1. Selected — The package is allowed to use the NC-SI lines, meaning the NC package might send data to the BMC.
2. De-selected — The package is not allowed to use the NC-SI lines, meaning, the NC package cannot send data to the BMC.

The BMC must select no more than one NC package at any given time. Package selection can be accomplished in one of two methods:

1. Select Package command — This command explicitly selects the NC package.
2. Any other command targeted to a channel in the package also implicitly selects that NC package.

Package de-select can be accomplished only by issuing the De-Select Package command. The BMC should always issue the Select Package command as the first command to the package before issuing channel-specific commands. For further details on package selection, refer to the NC-SI specification.

### 10.6.4.2 Channel States

A NC channel can be in one of the following states:

1. Initial State — The channel only accepts the Clear Initial State command (the package also accepts the Select Package and De-Select Package commands).
2. Active state — This is the normal operational mode. All commands are accepted.

For normal operation mode, the BMC should always send the Clear Initial State command as the first command to the channel.

### 10.6.4.3 Discovery

After interface power-up, the BMC should perform a discovery process to discover the NCs that are connected to it. This process should include an algorithm similar to the following:

1. For package\_id=0x0 to MAX\_PACKAGE\_ID
  - a. Issue Select Package command to package ID package\_id
  - b. If a response was received then

For internal\_channel\_id = 0x0 to MAX\_INTERNAL\_CHANNEL\_ID

Issue a Clear Initial State command for package\_id | internal\_channel\_id (the combination of package\_id and internal\_channel\_id to create the channel ID).

If a response was received then

Consider internal\_channel\_id as a valid channel for the package\_id package

The BMC can now optionally discover channel capabilities and version ID for the channel

Else (If not a response was not received, then issue a Clear Initial State command three times.

Issue a De-Select Package command to the package (and continue to the next package).

- c. Else, if a response was not received, issue a Select Packet command three times.

### 10.6.4.4 Configurations

This section details different configurations that should be performed by the BMC.

The BMC should not consider any configuration valid unless the BMC has explicitly configured it after every reset (entry into the initial state). As a result, the BMC should re-configure everything at power-up and channel/package resets.

#### 10.6.4.4.1 NC Capabilities Advertisement

NC-SI defines the Get Capabilities command. It is recommended that the BMC use this command and verify that the capabilities match its requirements before performing any configurations. For example, the BMC should verify that the NC supports a specific AEN before enabling it.

#### 10.6.4.4.2 Receive Filtering

In order to receive traffic, the BMC must configure the NC with receive filtering rules. These rules are checked on every packet received on the LAN interface (such as from the network). Only if the rules matched, will the packet be forwarded to the BMC.

##### 10.6.4.4.2.1 MAC Address Filtering

NC-SI defines three types of MAC address filters: unicast, multicast and broadcast. To be received (not dropped) a packet must match at least one of these filters. The BMC should set one MAC address using the Set MAC Address command and enable broadcast and global multicast filtering.

###### 10.6.4.4.2.1.1 Unicast/Exact Match (Set MAC Address Command)

This filter filters on specific 48-bit MAC addresses. The BMC must configure this filter with a dedicated MAC address.

The NC might expose three types of unicast/exact match filters (such as MAC filters that match on the entire 48 bits of the MAC address): unicast, multicast and mixed. The I350 exposes two mixed filters, which might be used both for unicast and multicast filtering. The BMC should use one mixed filter for its MAC address.

**Note:** The MNGONLY bit matching the unicast filter (bit 5) is set by the first set MAC address command received from the BMC. It will not be cleared by further commands. If the MAC address is shared with the host and filter reductions are applied, the MNGONLY bit of the unicast filter should be cleared after each Set MAC address command using the *Set Intel Filters — Manageability Only Command* ([Section 10.6.3.5.3](#)).

Refer to NC-SI specification — Set MAC Address for further details.

###### 10.6.4.4.2.1.2 Broadcast (Enable/Disable Broadcast Filter Command)

NC-SI defines a broadcast filtering mechanism which has the following states:

1. Enabled — All broadcast traffic is blocked (not forwarded) to the BMC, except for specific filters (such as ARP request, DHCP, and NetBIOS).
2. Disabled — All broadcast traffic is forwarded to the BMC, with no exceptions.

Refer to NC-SI specification Enable/Disable Broadcast Filter command.

###### 10.6.4.4.2.1.3 Global Multicast (Enable/Disable Global Multicast Filter)

NC-SI defines a multicast filtering mechanism which has the following states:

1. Enabled — All multicast traffic is blocked (not forwarded) to the BMC.
2. Disabled — All multicast traffic is forwarded to the BMC, with no exceptions.

The recommended operational mode is Enabled, with specific filters set. Not all multicast filtering modes are necessarily supported. Refer to NC-SI specification Enable/Disable Global Multicast Filter command for further details.

#### 10.6.4.4.3 VLAN

NC-SI defines the following VLAN work modes:

| Mode       | Command and Name                              | Descriptions                                                                    |
|------------|-----------------------------------------------|---------------------------------------------------------------------------------|
| Disabled   | Disable VLAN command                          | In this mode, no VLAN frames are received.                                      |
| Enabled #1 | Enable VLAN command with VLAN only            | In this mode, only packets that matched a VLAN filter are forwarded to the BMC. |
| Enabled #2 | Enable VLAN command with VLAN only + non-VLAN | In this mode, packets from mode 1 + non-VLAN packets are forwarded.             |
| Enabled #3 | Enable VLAN command with Any-VLAN + non-VLAN  | In this mode, packets are forwarded regardless of their VLAN state.             |

Refer to NC-SI specification — Enable VLAN command for further details.

The I350 only supports modes #1 and #3. Recommendation:

1. Modes:
  - a. If VLAN is not required — Use the disabled mode.
  - b. If VLAN is required — Use the enabled #1 mode.
2. If enabling VLAN, The BMC should also set the active VLAN ID filters using the NC-SI Set VLAN Filter command prior to setting the VLAN mode.

#### 10.6.4.5 Pass-Through Traffic States

The BMC has independent, separate controls for enablement states of the receive (from LAN) and of the transmit (to LAN) pass-through paths.

#### 10.6.4.6 Channel Enable

This mode controls the state of the receive path:

1. Disabled — The channel does not pass any traffic from the network to the BMC.
2. Enabled — The channel passes any traffic from the network (that matched the configured filters) to the BMC.

This state also affects AENs: AENs is only sent in the enabled state.

The default state is disabled.

It is recommended that the BMC complete all filtering configuration before enabling the channel.

#### 10.6.4.7 Network Transmit Enable

This mode controls the state of the transmit path:

1. Disabled — the channel does not pass any traffic from the BMC to the network.
2. Enabled — the channel passes any traffic from the BMC (that matched the source MAC address filters) to the network.

The default state is disabled.

The NC filters pass-through packets according to their source MAC address. The NC tries to match that source MAC address to one of the MAC addresses configured by the Set MAC Address command. As a result, the BMC should enable network transmit only after configuring the MAC address.

It is recommended that the BMC complete all filtering configuration (especially MAC addresses) before enabling the network transmit.

This feature can be used for fail-over scenarios. See [Section 10.6.8.3](#).

## 10.6.5 Asynchronous Event Notifications

The asynchronous event notifications are unsolicited messages sent from the NC to the BMC to report status changes (such as link change, operating system state change, etc.).

Recommendations:

- The BMC firmware designer should use AENs. To do so, the designer must take into account the possibility that a NC-SI response frame (such as a frame with the NC-SI EtherType), arrives out-of-context (not immediately after a command, but rather after an out-of-context AEN).
- To enable AENs, the BMC should first query which AENs are supported, using the Get Capabilities command, then enable desired AEN(s) using the Enable AEN command, and only then enable the channel using the Enable Channel command.

## 10.6.6 Querying Active Parameters

The BMC can use the Get Parameters command to query the current status of the operational parameters.

## 10.6.7 Resets

In NC-SI there are two types of resets defined:

1. Synchronous entry into the initial state.
2. Asynchronous entry into the initial state.

Recommendations:

- It is very important that the BMC firmware designer keep in mind that following any type of reset, all configurations are considered as lost and thus the BMC must re-configure everything.
- As an asynchronous entry into the initial state might not be reported and/or explicitly noticed, the BMC should periodically poll the NC with NC-SI commands (such as Get Version ID, Get Parameters, etc.) to verify that the channel is not in the initial state. Should the NC channel respond to the command with a Clear Initial State Command Expected reason code, the BMC should consider the channel (and most probably the entire NC package) as if it underwent a (possibly unexpected) reset event. Thus, the BMC should re-configure the NC. See the NC-SI specification section on Detecting Pass-through Traffic Interruption.
- The Intel recommended polling interval is 2-3 seconds.

For exact details on the resets, refer to NC-SI specification.

## 10.6.8 Advanced Workflows

### 10.6.8.1 Multi-NC Arbitration

As described in [Section 10.6.1.2](#), in a multi-NC environment, there is a need to arbitrate the NC-SI lines.

[Figure 10-10](#) shows the system topology of such an environment.

**Figure 10-10 Multi-NC Environment**

See [Figure 10-10](#). The NC-SI Rx lines are shared between the NCs. To enable sharing of the NC-SI Rx lines, NC-SI has defined an arbitration scheme.

The arbitration scheme mandates that only one NC package can use the NC-SI Rx lines at any given time. The NC package that is allowed to use these lines is defined as selected. All the other NC packages are de-selected.

NC-SI has defined two mechanisms for the arbitration scheme:

1. Package selection by the BMC. In this mechanism, the BMC is responsible for arbitrating between the packages by issuing NC-SI commands (Select/De-Select Package). The BMC is responsible for having only one package selected at any given time.
2. Hardware arbitration. In this mechanism, two additional pins on each NC package are used to synchronize the NC package. Each NC package has an ARB\_IN and ARB\_OUT line and these lines are used to transfer Tokens. A NC package that has a token is considered selected.

**Note:** Hardware arbitration is enabled by the NC-SI ARB Enable EEPROM bit (See [Section 6.2.22](#)) and the NC-SI HW arbitration support EEPROM bit (see [Section 6.3.9.7](#)).

For details on Hardware arbitration, refer to the NC-SI specification.

### 10.6.8.2 Package Selection Sequence Example

Following is an example work flow for a BMC and occurs after the discovery, initialization, and configuration.

Assuming the BMC needs to share the NC-SI bus between packages, the BMC should:

1. Define a time-slot for each device.
2. Discover, initialize, and configure all the NC packages and channels.
3. Issue a De-Select Package command to all the channels.
4. Set active\_package to 0x0 (or the lowest existing package ID).
5. At the beginning of each time slot the BMC should:
  - a. Issue a De-Select Package to the active\_package. The BMC must then wait for a response and then an additional timeout for the package to become de-selected (200  $\mu$ s). See the NC-SI specification table 10 — parameter NC Deselect to Hi-Z Interval.
  - b. Find the next available package (typically active\_package = active\_package + 1).
  - c. Issue a Select Package command to active\_package.

### 10.6.8.3 Multiple Channels (Fail-Over)

In order to support a fail-over scenario, it is required from the BMC to operate two or more channels. These channels might or might not be in the same package.

The key element of a fault-tolerance fail-over scenario is having two (or more) channels identifying to the switch with the same MAC address, but only one of them being active at any given time (such as switching the MAC address between channels). To accomplish this, NC-SI provides the following commands:

1. Enable Network Tx command — This command enables shutting off the network transmit path of a specific channel. This enables the BMC to configure all the participating channels with the same MAC address but only enable one of them.
2. Link Status Change AEN or Get Link Status command.

#### 10.6.8.3.1 Fail-Over Algorithm Example

The following is a sample workflow for a fail-over scenario for the I350 quad-port GbE controller (one package and four channels):

1. BMC initializes and configures all channels after power-up. However, the BMC uses the same MAC address for all of the channels.
2. The BMC queries the link status of all the participating channels. The BMC should continuously monitor the link status of these channels. This can be accomplished by listening to AENs (if used) and/or periodically polling using the Get Link Status command.
3. The BMC then only enables channel 0 for network transmission.
4. The BMC then issues a gratuitous ARP (or any other packet with its source MAC address) to the network. This packet informs the switch that this specific MAC address is registered to channel 0's specific LAN port.
5. The BMC begins normal workflow.
6. Should the BMC receive an indication (AEN or polling) that the link status for the active channel (channel 0) has changed, the BMC should:
  - a. Disable channel0 for network transmission.

- b. Check if a different channel is available (link is up).
- c. If found:
  - Enable network TX for that specific channel.
  - Issue a gratuitous ARP (or any other packet with its source MAC address) to the network. This packet informs the switch that this specific MAC address is registered to channel 0's specific LAN port.
  - Resume normal workflow.
  - If not found, report the error and continue polling until a valid channel is found.

The above algorithm can be generalized such that the start-up and normal workflow are the same. In addition, the BMC might need to use a specific channel (such as channel 0). In this case, the BMC should switch the network transmit to that specific channel as soon as that channel becomes valid (link is up).

Recommendations:

- Wait for a link-down-tolerance timeout before a channel is considered invalid. For example, a link re-negotiation might take a few seconds (normally 2 to 3 or might be up to 9). Thus, the link must be re-established after a short time.
- Typically, this timeout is recommended to be three seconds.
- Even when enabling and using AENs, periodically poll the link status, as dropped AENs might not be detected.

#### 10.6.8.4 Statistics

The BMC might use the statistics commands as defined in NC-SI. These counters are meant mostly for debug purposes and are not all supported.

The statistics are divided into three commands:

1. Controller statistics — These are statistics on the primary interface (to the Host operating system). See the NC-SI specification for details.
2. NC-SI statistics — These are statistics on the NC-SI control frames (such as commands, responses, AENs, etc.). See the NC-SI specification for details.

NC-SI pass-through statistics — These are statistics on the NC-SI pass-through frames. See the NC-SI specification for details.

#### 10.6.9 External Link Control

The BMC can use the NC-SI Set Link command to control the external interface link settings. This command enables the BMC to set the auto-negotiation, link speed, duplex, and other parameters.

This command is only available when the Host operating system is not present. Indicating the Host operating system status can be obtained via the Get Link Status command and/or Host OS Status Change AEN command.

Recommendation:

- Unless explicitly needed, it is not recommended to use this feature. The NC-SI Set Link command does not expose all the possible link settings and/or features. This might cause issues under different scenarios. Even if you decided to use this feature, use it only if the link is down (trust the I350 until proven otherwise).

- It is recommended that the BMC first query the link status using the Get Link Status command. The BMC should then use this data as a basis and change only the needed parameters when issuing the Set Link command.

For details, refer to the NC-SI specification.

### 10.6.9.1 Set Link While LAN PCIe Functionality is Disabled

In cases where the I350 is used solely for manageability and its LAN PCIe function is disabled, using the NC-SI Set Link command while advertising multiple speeds and enabling auto-negotiation results in the lowest possible speed chosen.

To enable link of higher a speed, the BMC should not advertise speeds that are below the desired link speed, as the lowest advertised link speed is chosen.

When the I350 is only used for manageability and the link speed advertisement is configured by the BMC, changes in the power state of the LAN device is not affected and the link speed is not re-negotiated by the LAN device.

## 10.7 MCTP

### 10.7.1 MCTP Overview

The Management Component Transport Protocol (MCTP) defines a communication model intended to facilitate communication between:

- Management controllers and other management controllers
- Management controllers and management devices

The communication model includes a message format, transport description, message exchange patterns, and configuration and initialization messages.

The basic MCTP specification is described in DMTF's DSP0236 document.

MCTP is designed so that it can potentially be used on many bus types. The protocol is intended to be used for intercommunication between elements of platform management subsystems used in computer systems, and is suitable for use in mobile, desktop, workstation, and server platforms.

Currently, specifications exists for MCTP over PCI Express (DMTF's DSP0238) and over SMBus (DMTF's DSP0237). A specification for MCTP over USB is also planned.

Management controllers such as a baseboard management controller (BMC) can use this protocol for communication between one another, as well as for accessing management devices within the platform.

#### 10.7.1.1 NC-SI Over MCTP

MCTP is a transport layer protocol that does not include the functionality required to control the pass through traffic required for BMC connection to the network or to allow the BMC to control the network controller. This functionality is provided by encapsulating NC-SI traffic as defined in DMTF's DSP0222 document.

The details of NC-SI over MCTP protocol are defined in the NC-SI Over MCTP Specification.

### 10.7.1.2 MCTP Usage Model

The I350 supports NC-SI over MCTP protocol over SMBus. A BMC can be connected to a I350 NIC through MCTP as described in Figure Note: . The MCTP interface will be used by the BMC to control the NIC and not for pass through traffic.

**Note:** MCTP over SMBus is not active while in Dr State. In this state, the I350 will not answer to SMBus commands.

**Figure 10-11 MCTP connections of the I350**

### 10.7.1.3 Simplified MCTP Mode

For some point to point implementations of MCTP the assembly process is simplified. In this mode, the Destination EID, Source EID, Packet sequence number, Tag Owner (TO) bit and Message tag are ignored and the assembly is based only on the SOM & EOM bits. This bit is set according to the Simplified MCTP bit in the MCTP configuration word in the NVM.

This mode is relevant only for MCTP over SMBus traffic

## 10.7.2 NC-SI to MCTP Mapping

The four network ports of the I350 (mapped to four NC-SI channels) are mapped to a single MCTP endpoint on SMBus.

The channels are not used for pass through traffic and are only used to define which port is currently being accessed for control or status update.

The topology used for MCTP connection is described in [Figure 10-12](#).

**Figure 10-12** MCTP endpoints topology

## 10.7.3 MCTP Over SMBus

The message format used for NC-SI over MCTP over SMBus is as follows:

| +0                              |                     |   |                    |   |   |   |   | +1                        |   |   |   |   |   |   |   | +2                              |   |   |   |                      |   |   |   | +3          |             |      |   |        |     |   |   |
|---------------------------------|---------------------|---|--------------------|---|---|---|---|---------------------------|---|---|---|---|---|---|---|---------------------------------|---|---|---|----------------------|---|---|---|-------------|-------------|------|---|--------|-----|---|---|
| 7                               | 6                   | 5 | 4                  | 3 | 2 | 1 | 0 | 7                         | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 7                               | 6 | 5 | 4 | 3                    | 2 | 1 | 0 | 7           | 6           | 5    | 4 | 3      | 2   | 1 | 0 |
| Destination Slave Address       |                     |   |                    |   |   |   | 0 | Command Code = MCTP = 0Fh |   |   |   |   |   |   |   | Byte count                      |   |   |   | Source Slave Address |   |   |   |             |             |      |   |        |     |   |   |
| MCTP Reserved                   |                     |   | Header version = 1 |   |   |   |   | Destination endpoint ID   |   |   |   |   |   |   |   | Source endpoint ID              |   |   |   |                      |   |   |   | S<br>O<br>M | E<br>O<br>M | SEQ# |   | T<br>O | Tag |   |   |

### 10.7.3.1 SMBus Discovery Process

The I350 follows the discovery process described in section 5.5 of the MCTP SMBus/I2C Transport Binding Specification (DSP0237). It indicates support for ASF in the SMBus getUID command (see [Section 10.5.9.5](#)). It will respond to any SMBus command using the MCTP command code - so that the bus owner knows the I350 supports MCTP.

### 10.7.3.2 SMBus over MCTP implementation notes

Given the limited usage of MCTP over SMBus in the I350, it is assumed that collisions on the SMBus will not occur or will be rare. Thus in case of lost arbitration, the I350 will drop the current transaction and will not try to send it again.

## 10.7.4 NC-SI Over MCTP

The I350 support for NC-SI over MCTP is similar to the support for NC-SI over RMII with the following exceptions that the format of the packets is modified to account for the new transport layer as described below.

### 10.7.4.1 NC-SI Packets Format

NC-SI over MCTP defines two different message type for pass through and for control packets.

Packets with a message type equal to the *Control packets message type* field (default = 0x02) in the EEPROM are NC-SI control packets (commands, responses and AENs) and packets with a message type equal to the *Pass through packets message type* field (default = 0x02) in the EEPROM are NC-SI pass through packets

**Note:****10.7.4.1.1 Control Packets**

The format used for Control packets (Commands, Responses and AENs) is as follow:

| +0                   |                                                    |   |   |                    |   |   |   | +1                      |   |   |   |   |   |   |   | +2                      |   |   |   |   |   |   |   | +3          |             |      |   |                      |     |   |   |  |  |  |  |

|              |
|--------------|
| SMBus header |
| MCTP header  |
| NC-SI header |
| NC-SI Data   |

Note that the MAC header and MAC FCS present when working over NC-SI are not part of the packet in MCTP mode.

### 10.7.5 MCTP Programming

The MCTP programming model is based on:

1. A set of MCTP commands used for the discovery process and for the link management. The list of supported commands is described in [Section 10.7.5.1](#).
2. A subset of the NC-SI commands used in the regular NC-SI interface, including all the OEM commands as described in [Section 10.6.2](#) (NC-SI programming I/F). The specific commands supported are listed in [Table 10-30](#) and [Table 10-33](#).

**Note:** For all MCTP commands (both native MCTP commands and NCSI over MCTP), the response uses the Msg tag received in the request with TO bit cleared.

## 10.7.5.1 MCTP Commands Support

Table 10-46 lists the MCTP commands supported by the I350.

**Table 10-46 MCTP commands support**

| Command Code | Command Name                       | General Description                                                                                                                                                                                    | I350 support as Initiator | I350 support as Responder |
|--------------|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|---------------------------|
| 0x00         | Reserved                           | Reserved                                                                                                                                                                                               | –                         | –                         |
| 0x01         | Set Endpoint ID                    | Assigns an EID to the endpoint at the given physical address.                                                                                                                                          | N/A                       | Yes                       |
| 0x02         | Get Endpoint ID                    | Returns the EID presently assigned to an endpoint. Also returns information about what type the endpoint is and its level of use of static EIDs. See <a href="#">Section 10.7.5.1.1</a> for details.   | No                        | Yes                       |
| 0x03         | Get Endpoint UUID                  | Retrieves a per-device unique UUID associated with the endpoint. See <a href="#">Section 10.7.5.1.2</a> for details.                                                                                   | No                        | Yes                       |
| 0x04         | Get MCTP Version Support           | Lists which versions of the MCTP control protocol are supported on an endpoint. See <a href="#">Section 10.7.5.1.3</a> for details.                                                                    | No                        | Yes                       |
| 0x05         | Get Message Type Support           | Lists the message types that an endpoint supports. See <a href="#">Section 10.7.5.1.4</a> for details.                                                                                                 | No                        | Yes                       |
| 0x06         | Get Vendor Defined Message Support | Used to discover an MCTP endpoint's vendor specific MCTP extensions and capabilities.                                                                                                                  | No                        | No                        |
| 0x07         | Resolve Endpoint ID                | Used to get the physical address associated with a given EID.                                                                                                                                          | No                        | N/A                       |
| 0x08         | Allocate Endpoint IDs              | Used by the bus owner to allocate a pool of EIDs to an MCTP bridge.                                                                                                                                    | N/A                       | N/A                       |
| 0x09         | Routing Information Update         | Used by the bus owner to extend or update the routing information that is maintained by an MCTP bridge.                                                                                                | N/A                       | N/A                       |
| 0x0A         | Get Routing Table Entries          | Used to request an MCTP bridge to return data corresponding to its present routing table entries.                                                                                                      | No                        | N/A                       |
| 0x0B         | Prepare for Endpoint Discovery     | Used to direct endpoints to clear their "discovered" flags to enable them to respond to the Endpoint Discovery command.                                                                                | N/A                       | Yes <sup>1</sup>          |
| 0x0C         | Endpoint Discovery                 | Used to discover MCTP-capable devices on a bus, provided that another discovery mechanism is not defined for the particular physical medium.                                                           | No                        | Yes <sup>1</sup>          |
| 0x0D         | Discovery Notify                   | Used to notify the bus owner that an MCTP device has become available on the bus.                                                                                                                      | No                        | N/A                       |
| 0x0E         | Reserved                           | Reserved                                                                                                                                                                                               | –                         | –                         |
| 0x0F         | Query Hop                          | Used to discover what bridges, if any, are in the path to a given target endpoint and what transmission unit sizes the bridges will pass for a given message type when routing to the target endpoint. | No                        | No                        |

1. These commands are supported only for MCTP over PCIe.

### 10.7.5.1.1 Get Endpoint ID

The Get Endpoint ID response of the I350 is described in the following table:

| Byte | Description     | Value |
|------|-----------------|-------|
| 1    | Completion Code |       |

| Byte | Description     | Value                                                                                         |
|------|-----------------|-----------------------------------------------------------------------------------------------|
| 2    | Endpoint ID     | 0x00 - EID not yet assigned<br>Otherwise - returns EID assigned using Set Endpoint ID command |
| 3    | Endpoint Type   | 0x00 (Dynamic EID, Simple Endpoint)                                                           |
| 4    | Medium Specific | SMBUS: 0x01 - Fairness arbitration protocol supported.<br>PCIe: 0x00                          |

### 10.7.5.1.2 Get Endpoint UUID

The UUID returned is calculated according to the following function:

Time Low = Read from NVM words at offset 0x9 and 0xA of Sideband Configuration Structure.

Time mid = Read from NVM word at offset 0xB of Sideband Configuration Structure

Time High and version = Read from NVM word at offset 0xC of Sideband Configuration Structure

Clock Sec and Reserved = Read from NVM word at offset 0xD of Sideband Configuration Structure

Node = Host MAC address of port 0 as stored in NVM.

### 10.7.5.1.3 Get MCTP Version Support

The following table describes the returned value according to the requested message type

| Byte | Description                | Message type |                                 |                        |           |
|------|----------------------------|--------------|---------------------------------|------------------------|-----------|
|      |                            | 0xFF(Base)   | 0x00 (Control protocol message) | 0x02 (NC-SI over MCTP) | All other |
| 1    | Completion Code            |              |                                 |                        | 0x80      |
| 2    | Version Number entry count | 1            | 1                               | 1                      | 0         |
| 6:3  | Version number entry       | 0xF1F0FF00   | 0xF1F0FF00                      | 1                      | 0         |

### 10.7.5.1.4 Get Message Type Support Command

The Get Message type support response of the I350 is described in the following table:

| Byte | Description                  | Value                                                |
|------|------------------------------|------------------------------------------------------|
| 1    | Completion Code              | 0x00                                                 |
| 2    | MCTP Message Type Count      | 0x01 - The I350 supports one additional message type |
| 3    | List of Message Type numbers | 0x02 (NC-SI over MCTP)                               |

### 10.7.5.1.5 Set Endpoint ID Command

The I350 supports the Set EID and Force EID operations defined in the Set Endpoint ID command. As endpoints in the I350 can be set only through their own interface, Set EID and Force EID are equivalent. The Reset EID and Set Discovered Flag operations are not relevant to the I350.

The Set Endpoint ID response of the I350 is described in the following table:

| Byte | Description       | Value                                         |
|------|-------------------|-----------------------------------------------|
| 1    | Completion Code   | 0x00                                          |
| 2    | Completion Status | [7:6] = 00 - Reserved                         |
|      |                   | [5:4] = 00 - EID assignment accepted          |
|      |                   | [3:2] = 00 - Reserved                         |
|      |                   | [1:0] = 00 - Device does not use an EID pool. |

## 10.8 Manageability Host Interface

This section details host interaction with the manageability portion of the I350. The information within this section is only available to the host driver, the BMC does not have access.

### 10.8.1 HOST CSR Interface (All Functions)

The software device driver of all functions communicates with the manageability block through CSR access. The manageability is mapped to address space 0x8800 to 0x8FFF on the slave bus of each function.

**Note:** Writing to address 0x8800 from any function is targeted to the same address in the RAM.

### 10.8.2 Host Slave Command Interface to Manageability

This interface is used by the software device driver for several of the commands and for delivering various types of data in both directions (Manageability-to-Host and Host-to-Manageability).

The address space is separated into two areas:

- Direct access to the internal data RAM: The internal shared (between Firmware and Software) RAM is mapped to address space 0x8800 to 0x8EFF. Writing/reading to this address space goes directly to the RAM.
- Control register is located at address 0x8F00.

#### 10.8.2.1 Host Slave Command Interface Low Level Flow

This interface is used for the external host software to access the manageability subsystem. Host software writes a command block or read data structure directly from the data RAM. Host software controls these transactions through a slave access to the control register.

The following flow shows the process of initiating a command to the manageability block:

1. The Software clears the *FWSTS.FWRI* flag (clear by write one) to clear any previous firmware reset indications.
2. The Software device driver takes ownership of the Management Host interface using the flow described in [Section 4.7.1](#).

3. The Software device driver reads the *HOST Interface Control* Register (See [Section 8.22.1.2](#)) and checks that the *Enable (HICR.En)* bit is set.
4. The Software device driver writes the relevant command block into the RAM area that is mapped to addresses 0x8800-0x8EFF.
5. The Software device driver sets the *Command (HICR.C)* bit in the *HOST Interface Control* Register (See [Section 8.22.1.2](#)). Setting this bit causes an interrupt to the ARC (can be masked).
6. The Software checks the *FWSTS.FWRI* flag to make sure a firmware reset didn't occur during the command processing. If this bit is set, the command may have failed.
7. The Software device driver polls the *HOST Interface Control* register for the *Command (HICR.C)* bit to be cleared by Firmware.
8. When Firmware finishes with the command, it clears the *Command (HICR.C)* bit (if Firmware replies with data, it should clear the bit only after the data is placed in the shared RAM area where the software device driver can read it).

If the Software device driver reads the *HOST Interface Control* register and the *HICR.SV* bit is set to 1b, then there is a valid status of the last command in the shared RAM. If the *HICR.SV* bit is not set, then the command has failed with no status in the RAM.

On completion of access to the shared RAM Software device driver should release ownership of the shared RAM using the flow described in [Section 4.7.2](#).

## 10.8.2.2 Host Slave Command Registers

### 10.8.2.2.1 Host Interface Control Register (CSR Address 0x8F00)

This register operates along with the host software/firmware interface (See [Section 8.22.1.2](#)).

## 10.8.2.3 Host Interface Structures

### 10.8.2.3.1 Host Interface Command Structure

[Table 10-47](#) describes the structure used by the Software device driver to send a command to Firmware using the Host slave command interface (shared RAM mapped to addresses 0x8800-0x8EFF).

**Table 10-47 Host Driver Command Structure**

| #Byte | Description                | Bit | Value             | Description                                                                                                                                                                                                                                                     |
|-------|----------------------------|-----|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | Command                    | 7:0 | Command Dependent | Specifies which host command to process.                                                                                                                                                                                                                        |
| 1     | Buffer Length              | 7:0 | Command Length    | Command Data Buffer length: 0 to 252, not including 32 bits of header.                                                                                                                                                                                          |
| 2     | Default/Implicit Interface | 0   | Command Dependent | Used for commands might refer to one of four interfaces (LAN or SMBus).<br>0b = Use default interface.<br>1b = Use specific interface.                                                                                                                          |
|       | Interface Number           | 2:1 | Command Dependent | Used when bit 0 (Default/Implicit interface) is set:<br>00b = Apply command for interface 0.<br>01b = Apply command for interface 1.<br>10b = Apply command for interface 2.<br>11b = Apply command for interface 3.<br>When bit 0 is set to 0b, it is ignored. |

**Table 10-47 Host Driver Command Structure**

| #Byte | Description | Bit | Value             | Description                                                                   |
|-------|-------------|-----|-------------------|-------------------------------------------------------------------------------|
|       | Reserved    | 7:3 | 0x0               | Reserved                                                                      |
| 3     | Checksum    | 7:0 | Defined Below     | Checksum signature.                                                           |
| 255:4 | Data Buffer | 7:0 | Command Dependent | Command Specific Data<br>Minimum buffer size: 0.<br>Maximum buffer size: 252. |

### 10.8.2.3.2 Host Interface Status Structure

Table 10-48 lists the structure used by Firmware to return a status to the Software device driver via the Host slave command interface. A status is returned after a command has been executed.

**Table 10-48 Status Structure Returned to Host Driver**

| #Byte | Description   | Bit | Value                                   | Description                                                                                                                                                                               |
|-------|---------------|-----|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | Command       | 7:0 | Command Dependent                       | Command ID.                                                                                                                                                                               |
| 1     | Buffer Length | 7:0 | Status Dependent                        | Status buffer length: 252:0                                                                                                                                                               |
| 2     | Return Status | 7:0 | Depends on Command<br>Executing Results | 0x1 Status OK<br>0x2 Illegal command ID<br>0x3 Unsupported command<br>0x4 Illegal payload length<br>0x5 Checksum failed<br>0x6 Data Error<br>0x7 Invalid parameter<br>0x8 - 0xFF Reserved |
| 3     | Checksum      | 7:0 | Defined Below                           | Checksum signature.                                                                                                                                                                       |
| 255:4 | Data Buffer   |     | Status Dependent                        | Status configuration parameters<br>Minimum Buffer Size: 0.<br>Maximal Buffer Size: 252.                                                                                                   |

### 10.8.2.3.3 Checksum Calculation Algorithm

The Host Command/Status structure is summed with this field cleared to 0b. The calculation is done using 8-bit unsigned math with no carry. The inverse of this sum is stored in this field (0b minus the result). Result: The current sum of this buffer (8-bit unsigned math) is 0b.

## 10.8.2.4 Host Interface Commands

### 10.8.2.4.1 Driver Info Host Command

This command is used to provide the driver information in NC-SI mode.

**Table 10-49 Driver Info Host Command**

| Byte | Name           | Bit | Value          | Description                                                                                                 |
|------|----------------|-----|----------------|-------------------------------------------------------------------------------------------------------------|
| 0    | Command        | 7:0 | 0xDD           | Driver info command.                                                                                        |
| 1    | Buffer Length  | 7:0 | 0x5            | Port Number + 4 bytes of the Driver info                                                                    |
| 2    | Reserved       | 7:0 | 0x0            | Reserved                                                                                                    |
| 3    | Checksum       | 7:0 |                | Checksum signature of the Host command.                                                                     |
| 4    | Port Number    | 7:0 | Port Number    | Indicates the port currently reporting its driver info                                                      |

Following is the status returned on this command:

**Table 10-50 Driver Info Host Status**

| Byte | Name          | Bit | Value | Description              |
|------|---------------|-----|-------|--------------------------|
| 0    | Command       | 7:0 | 0xDD  | Driver Info command      |
| 1    | Buffer Length | 7:0 | 0x0   | No data in return status |
| 2    | Return Status | 7:0 | 0x1   | 0x1 for good status      |
| 3    | Checksum      | 7:0 |       | Checksum signature       |

### 10.8.2.4.2 Host Proxying Commands

Software Device driver will send to Firmware via shared RAM interface the following Proxying commands, using the interface described in [Section 10.8.2.1](#):

1. Get Firmware Proxying Capabilities Command (See [Table 10-51](#)) to receive information on Protocol offloads supported.
2. Set Firmware Proxying Configuration Command (See [Table 10-53](#)) to define the required proxying behavior.
3. Send the required Proxying information for the Protocol offloads supported by Firmware via the following commands:
  - a. Set ARP Proxy Table Entry (See [Table 10-55](#)).
  - b. Set NS (Neighbor Solicitation) Proxy Table Entry (See [Table 10-57](#)).

Following the reception of the commands, Firmware will acknowledge execution of the command via the shared RAM interface using the following responses according to the command issued:

1. Get Firmware Proxying Capabilities Response (See [Table 10-52](#)).
2. Set Firmware Proxying Configuration Response (See [Table 10-54](#)).
3. Acknowledge reception of Proxying information via the following responses:
  - a. Set ARP Proxy Table Entry Response (See [Table 10-56](#)).
  - b. Set NS (Neighbor Solicitation) Proxy Table Entry Response (See [Table 10-58](#)).

#### 10.8.2.4.2.1 Get Firmware Proxying Capabilities

This command is used to provide the driver information on protocol offload types supported by the I350.

**Table 10-51 Get Firmware Proxying Capabilities Command**

| Byte | Name          | Bit | Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|---------------|-----|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | Command       | 7:0 | 0xEA        | GET Firmware Proxying Capabilities                                                                                                                                                                                                                                                                                                                                                                                                      |

| 4    | Port Number   | 7:0 | Port Number | Indicates the port number that the command is targeted at.                                                                                                                                                                                                                                                                                                                                                                              |
| 5    | Page          | 7:0 | 0x1         | Get capabilities page number<br>If response exceeds 256 bytes including header (Maximum page size), Software should issue multiple Get Firmware Proxying Capabilities commands with increasing page number until a response with buffer length smaller than 252 is received or a response with a Status field with an Unsupported Page Number is received.<br><b>Note:</b> Maximum Page size is 256 Bytes including Header information. |

Firmware returns the following status for this command:

**Note:** The Firmware status reply includes a series of two values  
{Protocol offload capability type and version, number of entries for this type of Protocol offload}  
Currently the following capabilities are defined, ARP proxy NS proxy and MLD support. If the structure is too big to transfer in one time the driver can ask for additional pages by incrementing the page field.

**Table 10-52 Get Firmware Proxying Capabilities Response**

| Byte | Name                       | Bit | Value                    | Description                                                                                                                                                      |

| 9    | NS proxy version 1         | 7:0 | 0x2                      |                                                                                                                                                                  |
| 10   | Number of NS proxy entries | 7:0 | Number of entries        | Number of NS entries supported                                                                                                                                   |
| 11   | MLD support                | 7:0 | Version of MLD supported | 0x0 - not supported<br>0x1 - MLD version 1 compatibility mode<br>0x2 - MLD version 2 compatibility mode<br>0x3 - Both versions supported<br>0x4 - x0FF: Reserved |

1. Note that this number should be 5. will be fixed in next product.

#### 10.8.2.4.2.2 Set Firmware Proxying Configuration

This command is used to provide information to Firmware on how to implement protocol offloads supported by the I350.

The Firmware Proxying Configuration command includes a series of two values

{Command type and version, Command Data for this type of command}

Currently only two Configuration commands are defined:

1. No Match - Command defines expected behavior when receiving a Proxying packet that's not supported.
2. D3 to D0 - Command defines expected behavior when the I350 moves from D3 to D0 state.

If the structure is too big to transfer in one time the driver can ask for additional pages by incrementing the page field.

**Table 10-53 Set Firmware Proxying Configuration Command**

| Byte | Name          | Bit | Value           | Description                                                                                                                                                                                                                                                                                                                                           |
|------|---------------|-----|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | Command       | 7:0 | 0xEB            | Set Firmware Proxying Configuration                                                                                                                                                                                                                                                                                                                   |

#### 10.8.2.4.2.3 Set ARP Proxy Table Entry

**Note:** To set an entry Software driver will post command with *Active* field set to 0x1. To disable an entry the driver must post this entry with the *Active* field set to 0x0. Driver must initially disable all unused entries.

**Table 10-55 Set ARP Proxy Table Entry Command**

| Byte  | Name                | Bit | Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

#### 10.8.2.4.2.4 Set NS (Neighbor Solicitation) Proxy Table Entry

**Note:** To set an entry Software driver will post command with *Active* field set to 0x1. To disable an entry the driver must post this entry with the *Active* field set to 0x0. Driver must initially disable all unused entries.

**Table 10-57 Set NS Proxy Table Entry Command**

| Byte | Name               | Bit | Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|--------------------|-----|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | Command            | 7:0 | 0x78        | Set NS proxy command                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 10.8.3 Host Isolate Support

If a BMC decides that a malicious software prevents its usage of the LAN, it may decide to isolate the NIC from its driver. This is done using the TCO reset command ([Section 10.6.3.12](#)).

If TCO isolate is enabled in the EEPROM (See [Section 6.3.7.3](#)), The TCO Isolate command will disable PCIe write operations to the LAN port. As the driver needs to access the CSR space in order to provide descriptors to the NIC, this operation will also stop the network traffic including OS2BMC and BMC to OS traffic as soon as the existing transmit and receive descriptor queues are exhausted.

# 11 Electrical/Mechanical Specification

## 11.1 Introduction

These specifications are subject to change without notice.

This chapter describes the I350 DC and AC (timing) electrical characteristics. This includes absolute maximum rating, recommended operating conditions, power sequencing requirements, DC and AC timing specifications. The DC and AC characteristics include generic digital 3.3V IO specification as well as other specifications supported by the I350.

## 11.2 Operating Conditions

**Table 11-1 Absolute Maximum Ratings<sup>1</sup>**

| Symbol               | Parameter                        | Min                   | Max   | Units |
|----------------------|----------------------------------|-----------------------|-------|-------|
| T <sub>case</sub>    | Case Temperature Under Bias      |                       | 100   | °C    |
| T <sub>storage</sub> | Storage Temperature Range        | -65                   | 140   | °C    |
| Vi/Vo                | 3.3V Compatible I/Os Voltage     | V <sub>ss</sub> - 0.5 | 4.6   | V     |
|                      | Analog 1.0 I/O Voltage           | V <sub>ss</sub> - 0.2 | 1.68  |       |
|                      | Analog 1.8 I/O Voltage           | V <sub>ss</sub> - 0.3 | 2.52  |       |
| VCC3P3               | 3.3V Periphery DC Supply Voltage | V <sub>ss</sub> - 0.5 | 4.6   | V     |
| VCC                  | 1.0V Core DC Supply Voltage      | V <sub>ss</sub> - 0.2 | 1.68V | V     |
| VCC1P8               | 1.8V Analog DC Supply Voltage    | V <sub>ss</sub> - 0.3 | 2.52  | V     |
| VCC1P0               | 1.0V Analog DC Supply Voltage    | V <sub>ss</sub> - 0.2 | 1.68V | V     |

1. Ratings in this table are those beyond which permanent device damage is likely to occur. These values should not be used as the limits for normal device operation. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## 11.2.1 Recommended Operating Conditions

**Table 11-2 Recommended Operating Conditions**

| Symbol | Parameter                                                             | Min | Max      | Units | Notes |
|--------|-----------------------------------------------------------------------|-----|----------|-------|-------|
| Ta     | Operating Temperature Range<br>Commercial<br>(Ambient; 0 CFS airflow) | -10 | 55<br>85 | °C    | 1,2,3 |

**Note:**

- For normal device operation, adhere to the limits in this table. Sustained operations of a device at conditions exceeding these values, even if they are within the absolute maximum rating limits, may result in permanent device damage or impaired device reliability. Device functionality to stated DC and AC limits is not guaranteed if conditions exceed recommended operating conditions.
- Recommended operation conditions require accuracy of power supply as defined in [Section 11.3.1](#).
- With external heat sink. Airflow required for operation in 85°C ambient temperature.

## 11.3 Power Delivery

### 11.3.1 Power Supply Specification

| VCC3P3 (3.3V) Parameters |                                                                                                                                                                       |      |       |       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|-------|
| Parameter                | Description                                                                                                                                                           | Min  | Max   | Units |
| Rise Time <sup>1</sup>   | Time from 10% to 90% mark                                                                                                                                             | 0.1  | 100   | mS    |
| Monotonicity             | Voltage dip allowed in ramp                                                                                                                                           | N/A  | 0     | mV    |
| Slope                    | Ramp rate at any given time between 10% and 90%<br>Min: $0.8 \cdot V(\text{min}) / \text{Rise time (max)}$<br>Max: $0.8 \cdot V(\text{max}) / \text{Rise time (min)}$ | 24   | 28800 | V/S   |
| Operational Range        | Voltage range for normal operating conditions                                                                                                                         | 3    | 3.6   | V     |
| Ripple <sup>2</sup>      | Maximum voltage ripple (peak to peak)                                                                                                                                 | N/A  | 70    | mV    |
| Overshoot                | Maximum overshoot allowed                                                                                                                                             | N/A  | 100   | mV    |
| Overshoot Settling Time  | Maximum overshoot allowed duration.<br>(At that time delta voltage should be lower than 5mv from steady state voltage)                                                | N/A  | 0.05  | mS    |
| Decoupling Capacitance   | Capacitance range                                                                                                                                                     | 15   |       | μF    |
| Capacitance ESR          | Equivalent series resistance of output capacitance                                                                                                                    | N/A  | 50    | mΩ    |
| VCC1P8 (1.8V) Parameters |                                                                                                                                                                       |      |       |       |
| Parameter                | Description                                                                                                                                                           | Min  | Max   | Units |

1. When using the internal voltage regulator control function, the rise time of the 3.3V rail should be at least 5 ms to avoid high current draw on startup.
2. Power supply voltage with ripple should not be below minimum power supply operating range.
3. Applies when using the internal LVR and SVR feature.

### 11.3.1.1 Power On/Off Sequence

On power-on, after 3.3V reaches 90% of its final value, all voltage rails (1.8V and 1.0V) are allowed 100 ms to reach their final operating values. However, to keep leakage current at a minimum, it is recommended to turn on power supplies almost simultaneously (with delay between supplies at most a few milliseconds).

For power-down, it is recommended to turn off all power rails at the same time and let power supply voltage decay.

**Table 11-3 Power Sequencing**

| Symbol             | Parameter                                                              | Min | Max | units |
|--------------------|------------------------------------------------------------------------|-----|-----|-------|
| T <sub>3_1</sub>   | VCC3P3 (3.3V) power supply stable to VCC1P0 (1.0V) power supply stable |     | 100 | ms    |
| T <sub>3_18</sub>  | VCC3P3 (3.3V) power supply stable to VCC1P8 (1.8V) power supply stable |     | 100 | ms    |
| T <sub>18_1</sub>  | VCC1P8 (1.8V) power supply stable to VCC1P0 (1.0V) power supply stable | 0   |     | ms    |
| T <sub>m-per</sub> | 3.3V power supply to PE_RST_N de-assertion <sup>1</sup>                | 100 |     | ms    |
| T <sub>m-ppo</sub> | 3.3V power supply to MAIN_PWR_OK assertion                             | 0   |     | ms    |
| T <sub>lpg</sub>   | Power Supplies Stable to LAN_PWR_GOOD assertion                        | 0   |     | ms    |

**Table 11-3 Power Sequencing (Continued)**

|                |                                                              |     |  |    |
|----------------|--------------------------------------------------------------|-----|--|----|
| Tlpg-per       | LAN_PWR_GOOD assertion to PE_RST_N de-assertion <sup>1</sup> | 100 |  | ms |
| Tper-m, Tppo-m | PE_RST_N, MAIN_PWR_OK off before 3.3V power supply down      | 0   |  | ms |
| Tlpgw          | LAN_PWR_GOOD de-assertion time <sup>2</sup>                  | 1   |  | ms |

1. If external LAN\_PWR\_GOOD is used, this time should be kept between LAN\_PWR\_GOOD assertion and PERST# de-assertion.
2. parameter relevant only if external LAN\_PWR\_GOOD used.

**Figure 11-1 Power and Reset Sequencing**

### 11.3.1.2 Power-On Reset Thresholds

The I350 internal Power-on Reset circuitry initiates a full chip reset when voltage levels of VCC3P3 and VCC1P0 power supplies are below certain thresholds. To avoid false power-on reset following power-up, voltage levels that trigger internal power-on reset when power supplies ramp-up and ramp-down differ.

**Table 11-4 Power-on Reset Thresholds**

| Symbol | Parameter                                      | Specifications |     |       | Units |
|--------|------------------------------------------------|----------------|-----|-------|-------|
|        |                                                | Min            | Typ | Max   |       |
| V1a    | Threshold for 3.3 V power supply in power-up   | 2.064          |     | 2.545 | V     |
| V2a    | Threshold for 3.3 V power supply in power-down | 2.010          |     | 2.476 | V     |
| V1b    | Threshold for 1.0 V power supply in power-up   | 0.53           |     | 0.8   | V     |
| V2b    | Threshold for 1.0 V power supply in power-down | 0.38           |     | 0.64  | V     |

The following diagram describes the reset thresholds.

**Figure 11-2** Power on Reset Thresholds

## 11.4 Ball Summary

See [Chapter 2](#) for balls description and ball out map.

## 11.5 Current Consumption

All the numbers in this section are based on the I350 A1 measurements.

**Table 11-5** Power Consumption 4 ports

|                                        |                 |     | No SVR and LVR |           |           |                  | SVR and LVR |                  |

## 11.6 DC/AC Specification

### 11.6.1 DC Specifications

#### 11.6.1.1 Digital I/O

**Table 11-8 Digital IO DC Electrical Characteristics (Note 3)**

| Symbol | Parameter             | Conditions                       | Min        | Max          | Units      | Note |
|--------|-----------------------|----------------------------------|------------|--------------|------------|------|
| VCC3P3 | Periphery supply      |                                  | 3.0        | 3.6          | V          |      |
| VCC    | Core supply           |                                  | 0.93       | 1.08         | V          |      |
| VOH    | Output High Voltage   | IOH = -8mA; VCC3P3 = Min         | 2.4        |              | V          |      |
|        |                       | IOH = -100 $\mu$ A; VCC3P3 = Min | VCC3P3-0.2 |              |            |      |
| VOL    | Output Low Voltage    | IOL = 8mA; VCC=Min               |            | 0.4          | V          |      |
|        |                       | IOL = 100 $\mu$ A; VCC=Min       |            | 0.2          | V          |      |
| VIH    | Input High Voltage    |                                  | 2.0        | VCC3P3 + 0.3 | V          | 1    |
| VIL    | Input Low Voltage     |                                  | -0.3       | 0.8          | V          | 1    |
| Iil    | Input Current         | VCC3P3 = Max; VI = 3.6V/GND      |            | +/- 10       | $\mu$ A    |      |
| PU     | Internal pullup       | VIL = 0V                         | 40         | 150          | k $\Omega$ | 2    |
|        | Built-in hysteresis   |                                  | 100        |              | mV         |      |
| Cin    | Input Pin Capacitance |                                  |            | 8            | pF         |      |
| Vos    | Overshoot             |                                  | N/A        | 4            | V          |      |
| Vus    | Undershoot            |                                  | N/A        | -0.4         | V          |      |

**Notes:**

1. The input buffer also has hysteresis > 100mV
2. Internal pullup Max characterized at slow corner (125C, VCC3P3=min, process slow); internal pullup Min characterized at fast corner (0C, VCC3P3=max, process fast).
3. Applies to PE\_RSTn, SFP0\_I2C\_CLK, SFP1\_I2C\_CLK, SFP2\_I2C\_CLK, SFP3\_I2C\_CLK, SFP0\_I2C\_DATA, SFP1\_I2C\_DATA, SFP2\_I2C\_DATA, SFP3\_I2C\_DATA, SRDS\_0\_SIG\_DET, SRDS\_1\_SIG\_DET, SRDS\_2\_SIG\_DET, SRDS\_3\_SIG\_DET, LAN\_PWR\_GOOD, DEV\_OFF\_N, M\_PWR\_OK, JTCK, JTDI, JTDO, JTMS, RSVD\_ARC\_JTAG, SDP0[3:0], SDP1[3:0], SDP2[3:0], SDP3[3:0], FLISH\_SI, FLISH\_SO, FLISH\_SCK, FLISH\_CE\_N, EE\_DI, EE\_DO, EE\_SK, EE\_CS\_N, LAN0\_DIS\_N, LAN1\_DIS\_N, LAN2\_DIS\_N, LAN3\_DIS\_N, and AUX\_PWR.

### 11.6.1.2 LEDs I/O

**Table 11-9 LED IO DC Electrical Characteristics**

| Symbol | Parameter           | Conditions                  | Min  | Max          | Units | Note |
|--------|---------------------|-----------------------------|------|--------------|-------|------|
| VCC3P3 | Periphery supply    |                             | 3.0  | 3.6          | V     |      |
| VCC    | Core supply         |                             | 0.93 | 1.08         | V     |      |
| VOH    | Output High Voltage | IOH = -16mA; VCC3P3 = Min   | 2.4  |              | V     |      |
| VOL    | Output Low Voltage  | IOL = 16mA; VCC=Min         |      | 0.4          | V     |      |
| VIH    | Input High Voltage  |                             | 2.0  | VCC3P3 + 0.3 | V     | 1    |
| VIL    | Input Low Voltage   |                             | -0.3 | 0.8          | V     | 1    |
| Iil    | Input Current       | VCC3P3 = Max; VI = 3.6V/GND |      | +/- 20       | μA    |      |
|        | Built-in hysteresis |                             | 100  |              | mV    |      |
| Vos    | Overshoot           |                             | N/A  | 4            | V     |      |
| Vus    | Undershoot          |                             | N/A  | -0.4         | V     |      |

**Notes:**

1. The input buffer also has hysteresis > 100mV
2. Applies to LED0[3:0], LED1[3:0], LED2[3:0] and LED3[3:0]

### 11.6.1.3 Open Drain I/Os

**Table 11-10 Open Drain DC Specifications (Note 1, 4)**

| Symbol   | Parameter              | Condition              | Min  | Max   | Units | Note |
|----------|------------------------|------------------------|------|-------|-------|------|
| VCC3P3   | Periphery supply       |                        | 3.0  | 3.6   | V     |      |
| VCC      | Core supply            |                        | 0.93 | 1.08  | V     |      |
| Vih      | Input High Voltage     |                        | 2.1  |       | V     |      |
| Vil      | Input Low Voltage      |                        |      | 0.8   | V     |      |
| Ileakage | Output Leakage Current | 0 < Vin < VCC3P3       |      | +/-10 | μA    | 2    |
| Vol      | Output Low Voltage     | @ Ipullup              |      | 0.4   | V     | 4    |
| Iol      | Output Low Current     | Vol=0.4V               | 6    |       | mA    |      |
| Cin      | Input Pin Capacitance  |                        |      | 8     | pF    | 3    |
| Ioffsmb  | Input leakage current  | VCC3P3 off or floating |      | +/-10 | μA    | 2    |

**Notes:**

1. Applies to SMBD, SMBCLK, SMBALRT\_N, PE\_WAKE\_N and VR\_EN pads.
2. Device meets this whether powered or not.
3. Characterized, not tested.
4. OD no high output drive. VOL max=0.4V at 6mA, VOL max=0.2V at 0.1mA

### 11.6.1.4 NC-SI Input and Output Pads

**Table 11-11 NC-SI Pads DC Specifications**

| Symbol  | Parameter            | Conditions                   | Min  | Max   | Units |
|---------|----------------------|------------------------------|------|-------|-------|
| VCC3P3  | Periphery supply     |                              | 3.0  | 3.6   | V     |
| VCC     | Core supply          |                              | 0.93 | 1.08  | V     |
| Vabs    | Signal voltage range |                              | -0.3 | 3.765 | V     |
| VOH     | Output High Voltage  | IOH = -4mA; VCC3P3 = Min     | 2.4  |       | V     |
| VOL     | Output Low Voltage   | IOL = 4mA; VCC3P3 = Min      |      | 0.4   | V     |
| VIH     | Input High Voltage   |                              | 2.0  |       | V     |
| VIL     | Input Low Voltage    |                              |      | 0.8   | V     |
| Vihyst  | Input hysteresis     |                              | 100  |       | mV    |
| Iil/Iih | Input Current        | VCC3P3 = Max; Vin = 3.6V/GND |      | 20    | μA    |
| Cin     | Input Capacitance    |                              |      | 5     | pF    |

**Note:** Applies to the NC-SI\_CLK\_OUT, NC-SI\_CRS\_DV, NC-SI\_RXD[1:0], **NC-SI\_ARB\_OUT**, NC-SI\_TX\_EN, NC-SI\_TXD[1:0], NC-SI\_CLK\_IN, **NC-SI\_ARB\_IN**.

## 11.6.2 Digital I/F AC Specifications

### 11.6.2.1 Reset Signals

The timing between the power up sequence and the different reset signals is described in [Figure 11-1](#) and in [Table 11-3](#).

#### 11.6.2.1.1 LAN\_PWR\_GOOD

The I350 uses an internal power on detection circuit in order to generate the iLAN\_PWR\_GOOD signal. Reset can also be implemented when the external power on detection circuit determines that the device is powered up and asserts the LAN\_PWR\_GOOD signal to reset the device.

### 11.6.2.2 SMBus

The following table indicates the timing guaranteed when the driver or the agent is performing the action. Where only a typical value is specified, the actual value will be within 2% of the value indicated.

**Table 11-12 SMBus Timing Parameters (Master Mode)**

| Symbol              | Parameter                                                                         | Min | Typ  | Max | Units |
|---------------------|-----------------------------------------------------------------------------------|-----|------|-----|-------|
| F <sub>SMB</sub>    | SMBus Frequency                                                                   |     | 84   | 100 | kHz   |
| T <sub>BUF</sub>    | Time between STOP and START condition driven by the I350                          | 4.7 | 6.56 |     | μs    |
| T <sub>HD:STA</sub> | Hold time after Start Condition. After this period, the first clock is generated. | 4   | 6.72 |     | μs    |
| T <sub>SU:STA</sub> | Start Condition setup time                                                        | 4.7 |      |     | μs    |
| T <sub>SU:STO</sub> | Stop Condition setup time                                                         | 4   | 6.88 |     | μs    |

**Table 11-12 SMBus Timing Parameters (Master Mode) (Continued)**

| Symbol        | Parameter                 | Min  | Typ  | Max  | Units   |
|---------------|---------------------------|------|------|------|---------|
| $T_{HD:DAT}$  | Data hold time            | 0.3  | 0.48 |      | $\mu s$ |
| $T_{SU:DAT}$  | Data setup time           | 0.25 |      |      | $\mu s$ |
| $T_{TIMEOUT}$ | Detect SMBClk low timeout | 26.2 |      | 31.5 | ms      |
| $T_{LOW}$     | SMBClk low time           | 4.7  | 5.76 |      | $\mu s$ |
| $T_{HIGH}$    | SMBClk high time          | 4    | 6.56 |      | $\mu s$ |

The following table indicates the timing requirements of the I350 when it is the receiver of the indicated signal.

**Table 11-13 SMBus Timing Parameters (Slave Mode)**

| Symbol       | Parameter                                                                         | Min<br>100KHz <sup>1</sup> | Min<br>400KHz <sup>2</sup> | Max | Units   |
|--------------|-----------------------------------------------------------------------------------|----------------------------|----------------------------|-----|---------|
| $F_{SMB}$    | SMBus Frequency                                                                   | 10                         | 10                         | 400 | kHz     |
| $T_{BUF}$    | Time between STOP and START condition driven by the I350.                         | 4.7                        | 1.3                        |     | $\mu s$ |
| $T_{HD:STA}$ | Hold time after Start Condition. After this period, the first clock is generated. | 4                          | 0.6                        |     | $\mu s$ |
| $T_{SU:STA}$ | Start Condition setup time                                                        | 4.7                        | 0.6                        |     | $\mu s$ |
| $T_{SU:STO}$ | Stop Condition setup time                                                         | 4                          | 0.6                        |     | $\mu s$ |
| $T_{HD:DAT}$ | Data hold time                                                                    | 300                        | 100                        |     | ns      |
| $T_{SU:DAT}$ | Data setup time                                                                   | 250                        | 100                        |     | ns      |
| $T_{LOW}$    | SMBClk low time                                                                   | 4.7                        | 1.3                        |     | $\mu s$ |
| $T_{HIGH}$   | SMBClk high time                                                                  | 4                          | 0.6                        |     | $\mu s$ |

1. Specifications based on SMBus specification
2. Specifications based on I<sup>2</sup>C specification for Fast-mode (400 KHz)

**Figure 11-3 SMBus I/F Timing Diagram**

### 11.6.2.3 I<sup>2</sup>C AC Specification

The following table indicates the timing of the I2C\_CLK and I2C\_DATA pins when operating in I<sup>2</sup>C mode.

**Table 11-14 I<sup>2</sup>C Timing Parameters**

| Symbol              | Parameter                                                                         | Min             | Typ | Max | Units |
|---------------------|-----------------------------------------------------------------------------------|-----------------|-----|-----|-------|
| F <sub>SCL</sub>    | I2C_CLK Frequency                                                                 |                 |     | 100 | kHz   |
| T <sub>BUF</sub>    | Time between STOP and START condition driven by the I350                          | 4.7             |     |     | μs    |
| T <sub>HD:STA</sub> | Hold time after Start Condition. After this period, the first clock is generated. | 4               |     |     | μs    |
| T <sub>SU:STA</sub> | Start Condition setup time                                                        | 4.7             |     |     | μs    |
| T <sub>SU:STO</sub> | Stop Condition setup time                                                         | 4               |     |     | μs    |
| T <sub>HD:DAT</sub> | Data hold time                                                                    | 50 <sup>1</sup> |     |     | ns    |
| T <sub>SU:DAT</sub> | Data setup time                                                                   | 0.25            |     |     | μs    |
| T <sub>LOW</sub>    | I2C_CLK low time                                                                  | 4.7             |     |     | μs    |
| T <sub>HIGH</sub>   | I2C_CLK high time                                                                 | 4               |     |     | μs    |

1. According to Atmel's AT24C01A/02/04 definition of the 2 wires interface.

**Figure 11-4 I<sup>2</sup>C I/F Timing Diagram**

### 11.6.2.4 FLASH AC Specification

The I350 is designed to support a serial flash. Applicable over the recommended operating range from Ta = -40C to +85C, VCC3P3 = 3.3V, Cload = 1 TTL Gate and 16 pF (unless otherwise noted). For FLASH I/F timing specification [Table 11-15](#) and [Figure 11-5](#).

**Table 11-15 FLASH I/F Timing Parameters**

| Symbol           | Parameter           | Min | Typ    | Max | Units | Note |
|------------------|---------------------|-----|--------|-----|-------|------|
| t <sub>SCK</sub> | SCK clock frequency | 0   | 15.625 | 20  | MHz   | [1]  |
| t <sub>RI</sub>  | Input rise time     |     | 2.5    | 20  | ns    |      |
| t <sub>FI</sub>  | Input fall time     |     | 2.5    | 20  | ns    |      |
| t <sub>WH</sub>  | SCK high time       | 20  | 32     |     | ns    | [2]  |

**Table 11-15 FLASH I/F Timing Parameters (Continued)**

| Symbol    | Parameter           | Min | Typ | Max | Units | Note |
|-----------|---------------------|-----|-----|-----|-------|------|
| $t_{WL}$  | SCK low time        | 20  | 32  |     | ns    | [2]  |
| $t_{CS}$  | CS high time        | 25  |     |     | ns    |      |
| $t_{CSS}$ | CS setup time       | 25  |     |     | ns    |      |
| $t_{CSH}$ | CS hold time        | 25  |     |     | ns    |      |
| $t_{SU}$  | Data-in setup time  | 5   |     |     | ns    |      |
| $t_H$     | Data-in hold time   | 5   |     |     | ns    |      |
| $t_V$     | Output valid        |     |     | 20  | ns    |      |
| $t_{HO}$  | Output hold time    | 0   |     |     | ns    |      |
| $t_{DIS}$ | Output disable time |     |     | 100 | ns    |      |

**Notes:**

1. Clock is 62.5MHz divided by 4. In Bit Banging mode maximum allowable frequency is 20MHz
2. 45% to 55% duty cycle.

**Figure 11-5 Flash Timing Diagram**

### 11.6.2.5 EEPROM AC Specification

The I350 is designed to support a standard serial EEPROM. Applicable over recommended operating range from  $T_a = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ ,  $V_{CC3P3} = 3.3\text{V}$ ,  $C_{load} = 1$  TTL Gate and 16pF (unless otherwise noted). For EEPROM I/F timing specification see [Table 11-16](#) and [Figure 11-6](#).

**Table 11-16 EEPROM I/F Timing Parameters**

| Symbol    | Parameter           | Min | Typ | Max | Units   | Note |
|-----------|---------------------|-----|-----|-----|---------|------|
| $t_{SCK}$ | SCK clock frequency | 0   | 2   | 2.1 | MHz     | [1]  |
| $t_{RI}$  | Input rise time     |     |     | 2   | $\mu$ s |      |
| $t_{FI}$  | Input fall time     |     |     | 2   | $\mu$ s |      |
| $t_{WH}$  | SCK high time       | 200 | 250 |     | ns      | [2]  |
| $t_{WL}$  | SCK low time        | 200 | 250 |     | ns      |      |
| $t_{CS}$  | CS high time        | 250 |     |     | ns      |      |
| $t_{CSS}$ | CS setup time       | 250 |     |     | ns      |      |
| $t_{CSH}$ | CS hold time        | 250 |     |     | ns      |      |
| $t_{SU}$  | Data-in setup time  | 50  |     |     | ns      |      |
| $t_H$     | Data-in hold time   | 50  |     |     | ns      |      |
| $t_V$     | Output valid        | 0   |     | 200 | ns      |      |
| $t_{HO}$  | Output hold time    | 0   |     |     | ns      |      |
| $t_{DIS}$ | Output disable time |     |     | 250 | ns      |      |

**Notes:**

1. Clock is 2MHz
2. 45% to 55% duty cycle.

**Figure 11-6 EEPROM Timing Diagram**

### 11.6.2.6 NC-SI AC Specification

The I350 is designed to support the standard DMTF NC-SI interface. For NC-SI I/F timing specification see [Table 11-17](#) and [Figure 11-7](#).

**Table 11-17 NC-SI AC Specifications**

| Symbol      | Parameter                                                                                                                     | Min | Typ | Max  | Units | Notes |
|-------------|-------------------------------------------------------------------------------------------------------------------------------|-----|-----|------|-------|-------|
| Tckf        | NCSI_CLK_IN Frequency                                                                                                         |     | 50  |      | MHz   | 2     |
| Rdc         | NCSI_CLK_IN Duty Cycle                                                                                                        | 35  |     | 65   | %     | 1     |
| Racc        | NCSI_CLK_IN accuracy                                                                                                          |     |     | 100  | ppm   |       |
| Tco         | Clock-to-out (10 pF =< load =<50 pF)<br>NCSI_RXD[1:0], NCSI_CRSDV and NCSI_ARB_OUT<br>Data valid from NCSI_CLK_IN rising edge | 2.5 |     | 12.5 | ns    | 4     |
| Tsu         | NCSI_TXD[1:0], NCSI_TX_EN and NCSI_ARB_IN Data<br>Setup to NCSI_CLK_IN rising edge                                            | 3   |     |      | ns    |       |
| Thold       | NCSI_TXD[1:0], NCSI_TX_EN Data hold from<br>NCSI_CLK_IN rising edge                                                           | 1   |     |      | ns    |       |
| Tor         | NCSI_RXD[1:0], NCSI_CRSDV and NCSI_ARB_OUT<br>Output Time rise                                                                | 0.5 |     | 6    | ns    | 3     |
| Tof         | NCSI_RXD[1:0], NCSI_CRSDV and NCSI_ARB_OUT<br>Output Time fall                                                                | 0.5 |     | 6    | ns    | 3     |
| Tckr/Tckf   | NCSI_CLK_IN Rise/Fall Time                                                                                                    | 0.5 |     | 3.5  | ns    |       |
| Tckor/Tckof | NCSI_CLK_OUT Rise/Fall Time                                                                                                   | 0.5 |     | 3.5  | ns    | 5     |

**Notes:**

1. Clock Duty cycle measurement: High interval measured from Vih to Vil points, Low from Vil to next Vih.
2. Clock interval measurement from Vih to Vih.
3. Load = 25 pF.
4. This timing relates to the output pins, while Tsu and Thd relate to timing at the input pins
5. 10 pF =< Load =< 30 pF

**Figure 11-7 NC-SI Timing Diagram**

### 11.6.2.7 JTAG AC Specification

The I350 is designed to support the IEEE 1149.1 standard. Following timing specifications are applicable over recommended operating range from  $T_a = 0^{\circ}\text{C}$  to  $+70^{\circ}\text{C}$ ,  $V_{CC3P3} = 3.3\text{V}$ ,  $C_{load} = 16\text{pF}$  (unless otherwise noted). For JTAG I/F timing specification see [Table 11-18](#) and [Figure 11-8](#).

**Table 11-18 JTAG I/F Timing Parameters**

| Symbol     | Parameter                | Min | Typ | Max | Units | Note |
|------------|--------------------------|-----|-----|-----|-------|------|
| $t_{JCLK}$ | JTCK clock frequency     |     |     | 10  | MHz   |      |
| $t_{JH}$   | JTMS and JTDI hold time  | 10  |     |     | nS    |      |
| $t_{JSU}$  | JTMS and JTDI setup time | 10  |     |     | nS    |      |
| $t_{JPR}$  | JTDO propagation Delay   |     |     | 15  | nS    |      |

**Notes:**

1. The table above applies to JTCK, JTMS, JTDI and JTDO.
2. Timing measured relative to JTCK reference voltage of  $V_{CC3P3}/2$ .

**Figure 11-8 JTAG AC Timing Diagram**

### 11.6.2.8 MDIO AC Specification

The I350 is designed to support the MDIO specifications defined in IEEE 802.3 clause 22. Following timing specifications are applicable over recommended operating range from  $T_a = 0^{\circ}\text{C}$  to  $+70^{\circ}\text{C}$ ,  $V_{CC3P3} = 3.3\text{V}$ ,  $C_{load} = 16\text{pF}$  (unless otherwise noted). For MDIO I/F timing specification see [Table 11-19](#), [Figure 11-9](#) and [Figure 11-10](#).

**Table 11-19 MDIO I/F Timing Parameters**

| Symbol     | Parameter           | Min | Typ | Max | Units | Note |
|------------|---------------------|-----|-----|-----|-------|------|
| $t_{MCLK}$ | MDC clock frequency |     |     | 2   | MHz   |      |
| $t_{MH}$   | MDIO hold time      | 10  |     |     | nS    |      |

**Table 11-19 MDIO I/F Timing Parameters**

| Symbol    | Parameter              | Min | Typ | Max | Units | Note |
|-----------|------------------------|-----|-----|-----|-------|------|
| $t_{MSU}$ | MDIO setup time        | 10  |     |     | nS    |      |
| $t_{MPR}$ | MDIO propagation Delay | 10  |     | 300 | nS    |      |

**Notes:**

1. The table above applies to MDIO0, MDC0, MDIO1, MDC1, MDIO2, MDC2, MDIO3, and MDC3.
2. Timing measured relative to MDC reference voltage of 2.0V ( $V_{ih}$ ).

**Figure 11-9 MDIO Input AC Timing Diagram**

**Figure 11-10 MDIO Output AC Timing Diagram**

### 11.6.2.9 SFP 2 Wires I/F AC Specification

According to Atmel's AT24C01A/02/04 definition of the 2 wires I/F bus.

### 11.6.2.10 PCIe/SerDes DC/AC Specification

The transmitter and receiver specification are given per PCIe Card Electromechanical Specification rev 2.0.

### **11.6.2.11      PCIe Specification - Receiver**

Specifications are from the PCIe v2.1 (2.5GT/s and 5GT/s) specification.

### **11.6.2.12      PCIe Specification - Transmitter**

Specifications are from the PCI Express\* 2.0 (5Gbps or 2.5Gbps) specification.

### **11.6.2.13      PCIe Specification - Input Clock**

The input clock for PCIe must be a differential input clock in frequency of 100 MHz. For full specifications please check the PCI-Express Card Electromechanical specifications (refclk specifications).

## **11.6.3          Serdes DC/AC Specification**

The Serdes interface supports the following standards:

1. PICMG 3.1 specification Rev 1.0 1000BASE-BX.
2. 1000BASE-KX electrical specification defined IEEE802.3ap clause 70.
3. SGMII on 1000BASE-BX or 1000BASE-KX compliant electrical interface (AC coupling with internal clock recovery).
4. SFP (Small Form factor Pluggable) Transceiver Rev 1.0

## **11.6.4          PHY Specification**

The specifications define the interface for the back-plane board connection, Interface to external 1000BASE-T PHY and the interface to fiber or SFP module.

DC/AC specification is according to Standard 802.3 and 802.3ab.

100 Base-T parameters are also described in standard ANSI X3.263.

## **11.6.5          XTAL/Clock Specification**

The 25 MHz reference clock of the I350 can be supplied either from a crystal or from an external oscillator. The recommended solution is to use a crystal.

### 11.6.5.1 Crystal Specification

**Table 11-20 Specification for External Crystal**

| Parameter Name                            | Symbol               | Recommended Value         | Conditions |
|-------------------------------------------|----------------------|---------------------------|------------|
| Frequency                                 | $f_o$                | 25.000 [MHz]              | @25 [°C]   |
| Vibration mode                            |                      | Fundamental               |            |
| Cut                                       |                      | AT                        |            |
| Operating /Calibration Mode               |                      | Parallel                  |            |
| Frequency Tolerance @25°C                 | $\Delta f/f_o$ @25°C | ±30 [ppm]                 | @25 [°C]   |
| Temperature Tolerance                     | $\Delta f/f_o$       | ±30 [ppm]                 |            |

### 11.6.5.2 External Clock Oscillator Specification

When using an external oscillator the following connection must be used:

**Figure 11-11 External Clock Oscillator Connectivity to the I350**

**Table 11-21 Specification for External Clock Oscillator**

| Parameter Name            | Symbol         | Value                | Conditions      |
|---------------------------|----------------|----------------------|-----------------|
| Frequency                 | $f_o$          | 25.0 [MHz]           | @25 [°C]        |
| External OSC Supply Swing | $V_{p-p}$      | $3.3 \pm 0.3$ [V]    |                 |
| Frequency Tolerance       | $\Delta f/f_o$ | $\pm 50$ [ppm]       | -20 to +70 [°C] |
| Operating Temperature     | $T_{opr}$      | -20 to +70 [°C]      |                 |
| Aging                     | $\Delta f/f_o$ | $\pm 5$ ppm per year |                 |

## 11.6.6 GbE PHY GE\_REXT Bias Connection

For the PHY circuit, an external resistor of 3.01KΩ (accuracy 1%) is used as reference for the internal bias currents. This resistor is connected to the GE\_REXT ball and GND as shown in [Figure 11-12](#).

Short connections for this resistor are compulsory.

Place the resistor as close as possible to the device (less than 1").

**Figure 11-12 GbE PHY Bias Connection**

### 11.6.7 SerDes SE\_RSET Bias Connection

For the SerDes circuit, an external resistor of  $2.37K\Omega$  (accuracy 1%) is used as reference for the internal bias currents. This resistor is connected to the SE\_RSET ball and GND as shown in [Figure 11-13](#).

Short connections for this resistor are compulsory.

Place the resistor as close as possible to the device (less than 1").

**Figure 11-13 SerDes Bias Connection**

### 11.6.8 PCIe PE\_TRIM Bias Connection

For the PCIe SerDEs circuit, an external resistor of 1.5K $\Omega$  (accuracy 1%) is used as reference for the internal bias currents. This resistor is connected between the PE\_TRIM1 and PE\_TRIM2 balls as shown in [Figure 11-14](#).

Short connections for this resistor are compulsory. Place the resistor as close as possible to the device (less than 1").

**Figure 11-14 PCIe Bias Connection**

## 11.6.9 Voltage Regulator Electrical Specifications

To reduce BOM cost the I350 supports generation of the 1.0V power supply from the 3.3V supply using an on-chip SVR (Switched Voltage Regulator) control circuit with an external inductor, PFET and NFET matched power transistors and some additional discrete components. The I350 also supports generation of the 1.8V power supply from the 3.3V power supply using a an on-chip LVR (Linear Voltage Regulator) control circuit with an external low cost BJT transistor (for additional information see [Section 3.5](#)).

### 11.6.9.1 1.0V SVR Electrical Specifications

Following table describes electrical performance of the 1.0V SVR when using the components specified in section [Section 11.9.1](#).

| Parameter                                      | Min  | Typ | Max | Unit              | Comments                                                                                                                                           |
|------------------------------------------------|------|-----|-----|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Regulator input voltage                        | 2.9  | 3.3 | 3.7 | V                 |                                                                                                                                                    |
| Junction Temperature                           | -25  |     | 125 | °C                |                                                                                                                                                    |
| Regulator output voltage                       | 1.0  |     |     | V                 | Programmable Output Voltage                                                                                                                        |
| Output Voltage Accuracy                        | -3   |     | +3  | %                 | Not including line and load regulation errors.                                                                                                     |
| Load Current                                   | 0.05 |     | 4.0 | A                 | Average Value, in PWM Mode                                                                                                                         |
| Load Current                                   |      |     | 1.0 | A                 | Average Value, in PFM Mode                                                                                                                         |
| Load Current                                   |      |     | 0.8 | A                 | Average Value, in Start-Up                                                                                                                         |
| Load regulation                                |      | 0.1 |     | %/A               | Output voltage droop versus load current                                                                                                           |
| Line regulation                                |      | 0.2 |     | %/V               | Output voltage change verses input supply voltage (VCC3P3)                                                                                         |
| Conversion Efficiency                          | 80   |     |     | %                 | Depends on load current and external FETs/ Inductor                                                                                                |
| Output Filter Capacitor Value (Cout)           | 22   |     | 110 | μF                | Tolerance Limit of ±10% Use a larger inductor to reduce this value                                                                                 |

### 11.6.9.2 SVR Efficiency

Following graph depicts SVR efficiency as a function of 1.0V current consumption.

**Figure 11-15 SVR Efficiency**

### 11.6.9.3 1.8V LVR Electrical Specifications

Following table describes electrical performance of the 1.8V LVR using the components specified in section [Section 11.9.2](#).

**Table 11-22 LVR DC Specifications**

| Parameter                  | Min  | Typ | Max  | Unit | Comments                                                               |
|----------------------------|------|-----|------|------|------------------------------------------------------------------------|
| Regulator input voltage    | 2.9  | 3.3 | 3.7  | V    |                                                                        |
| Junction Temperature       | -25  |     | 125  | °C   |                                                                        |
| Regulator output voltage   | 1.8  |     |      | V    |                                                                        |
| Output Voltage Accuracy    | -3.5 |     | +3.5 | %    | Not including line and load regulation errors.                         |
| Output load capacitance    | 22   |     |      | μF   | For loop stability. To reduce capacitance ESR use multiple capacitors. |
| Load capacitance tolerance | -5   |     | +5   | %    | For wider tolerance increase minimum load capacitance to compensate.   |
| PNP beta                   | 85   | 200 | 375  |      | At $I_C = 0.5A$                                                        |

**Table 11-22 LVR DC Specifications**

| Parameter                | Min                    | Typ  | Max | Unit    | Comments                                                                  |
|--------------------------|------------------------|------|-----|---------|---------------------------------------------------------------------------|
| PNP transition frequency | 40                     | 120  | 200 | MHz     | $f_T$                                                                     |
| Load regulation          |                        | -2   | -6  | mV/A    | Output voltage droop versus load current                                  |
| Line regulation          |                        | 0.02 | 0.1 | %/V     | Output voltage change versus input supply voltage (VCC3P3)                |
| Load Current             | 10                     | 100  | 600 | mA      |                                                                           |
| HIZ Leakage              |                        |      | 10  | $\mu$ A | On LVR_1P8_CTRL pin with 1.8V load when VR_EN pin is connected to ground. |
| Load dependent current   | $I_{LOAD}/\beta_{PNP}$ |      |     | mA      | Sunk by LVR_1P8_CTRL pin                                                  |

**Table 11-23 1.8V LVR AC Specifications**

| Parameter                 | Min | Typ | Max | Unit    | Comments                                |
|---------------------------|-----|-----|-----|---------|-----------------------------------------|

| Output voltage undershoot |     | 5   |     | %       | Max to min load step                    |
| Power up time             |     | 20  |     | $\mu$ S |                                         |
| Output voltage overshoot  |     | 2   |     | %       | During power up                         |

## 11.7 Package

The I350 is assembled in 2 packages:

1. A 17x17 PBGA package that's footprint compatible with 82580.
2. A 25x25 PBGA package with a dual 10/100/1000BASE-T copper interface.

### 11.7.1 Mechanical Specification for the 17x17 PBGA Package.

**Table 11-24 I350 17x17 Package Mechanical Specifications**

| Body Size | Ball Count | Ball Pitch | Ball Matrix                    | Substrate |
|-----------|------------|------------|--------------------------------|-----------|
| 17x17     | 256        | 1.0 mm     | 16 x 16 array, fully populated | 4 layers  |

**Note:** The I350 uses the P-free SAC305 solder ball (P<2 ppm) and WF6063M5 ball attach flux. The package pad copper size is 0.6 mm in diameter. The solder mask opening is 0.45 mm in diameter.

11.7.1.1 17x17 PBGA Package Schematics

## 11.7.2 Mechanical Specification for the 25x25 PBGA Package

**Table 11-25 I350 25x25 Package Mechanical Specifications**

| Body Size | Ball Count | Ball Pitch | Ball Matrix                    | Substrate |
|-----------|------------|------------|--------------------------------|-----------|
| 25x25     | 576        | 1.0 mm     | 16 x 16 array, fully populated | 4 layers  |

11.7.2.1 25x25 PBGA Package Schematics

## 11.8 EEPROM Flash Devices

While Intel does not make recommendations regarding these devices, the following devices have been used successfully in previous designs.

### 11.8.1 Flash

Type: SPI Flash

Size: 256 Kbytes (typical), depending on application.

**Table 11-26 Serial Flash Table**

| Density | Intel PN                                                                                                                                     | Atmel PN            | STM PN        | SST PN      |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------|---------------------|---------------|-------------|
| 512KBit |                                                                                                                                              | AT25F512N-10SI-2.7  | M25P05-AVMN6T | SST25VF512A |
| 1MBit   |                                                                                                                                              | AT25F1024N-10SI-2.7 | M25P10-AVMN6T | SST25VF010A |
| 2MBit   |                                                                                                                                              | AT25F2048N-10SI-2.7 | M25P20-AVMN6T | SST25LF020A |
| 4MBit   |                                                                                                                                              | AT25F4096N-10SI-2.7 | M25P40-AVMN6T | SST25VF040A |

## 11.9 Voltage Regulator External Components

Components listed in following sections can be used when the I350 1.0V power supply and 1.8V power supply are generated from the 3.3V power supply using on-chip control circuits with external power transistors and other discrete components.

### 11.9.1 1.0V SVR External Components

Figure 11-16 depicts the external components required for 1.0V SVR operation.

Figure 11-16 1.0V SVR Connection

Following external components can be used for the 1.0V SVR circuit.

Table 11-28 Recommended 1.0V SVR External FETs

| Vendor                          | PFET          | NFET          |
|---------------------------------|---------------|---------------|
| Vishay                          | SiA417DJ      | SiA414DJ      |
| Alpha and Omega                 | AO4437        | AO4402L       |
| Advanced Power Electronics Corp | AP9620GM-HF   | AP9410GM-HF   |
| Diodes, Inc.                    | DMP2022LSS-13 | DMN2009LSS-13 |

Table 11-29 Recommended 1.0V SVR External Capacitors and Resistors

| Symbol | Recommended Value       | Notes                                             |
|--------|-------------------------|---------------------------------------------------|
| L1     | 1 $\mu$ H $\pm$ 20%     | Should support saturation current of at least 6A. |
| R1     | 680 $\Omega$ $\pm$ 5%   |                                                   |
| R2     | 4.7 K $\Omega$ $\pm$ 5% |                                                   |
| R3     | 39 K $\Omega$ $\pm$ 5%  |                                                   |

**Table 11-29 Recommended 1.0V SVR External Capacitors and Resistors**

| Symbol | Recommended Value                                                                                               | Notes                                                                                                                    |
|--------|-----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| C1     | 2.2 nF ±10%                                                                                                     |                                                                                                                          |
| C2     | 10 pF ±10%                                                                                                      |                                                                                                                          |
| C3     | 680 pF ±10%                                                                                                     |                                                                                                                          |
| Cout   | 1. 1 X 47 $\mu$ F ±10%<br>2. 3 X 22 $\mu$ F ±10%<br>3. 3 X 100 nF ±10%<br>4. 3 X 10 nF ±10%<br>5. 3 X 1 nF ±10% | Capacitors listed for Cout are a minimum requirement to reduce ESR. Adding additional capacitance will reduce overshoot. |

## 11.9.2 1.8V LVR External Components

Figure 11-17 depicts the external components required for 1.8V LVR operation.

**Figure 11-17 1.8V LVR Connection**

Following external components can be used for the 1.8V LVR.

**Table 11-30 1.8V LVR External Components**

| PNP BJT  | Comments                 |
|----------|--------------------------|
| BCP69    |                          |
| NJT4030P | Higher $f_T$ and $\beta$ |

**Notes:**

1. Bulk capacitors – Aluminum electrolytic, X5R, or X7R ceramic capacitors valued from 22  $\mu\text{F}$  to 150  $\mu\text{F}$  are required on the regulator output. The design shall be stable using values throughout this entire range although transient response may be determined by the ESR of the bulk capacitors chosen. Ceramic capacitors generally yield lower over and undershoot in response to load current changes. When all ceramic capacitors are used, a minimum of one 1  $\mu\text{F}$  capacitor are required to control load impedance and insure stability in the 1 to 10 MHz range.
2. Distributed bypass capacitors – Multiple X5R, or X7R 0.1  $\mu\text{F}$  chip ceramic capacitors (minimum 3) should be used. Additional smaller value caps may also be added for improved high-frequency performance.

**NOTE:**      *This page intentionally left blank.*

## 12 Design Guidelines

### 12.1 Ethernet Interface

#### 12.1.1 Magnetics for 1000 BASE-T

Magnetics for the I350 can be either integrated or discrete.

The magnetics module has a critical effect on overall IEEE and emissions conformance. The device should meet the performance required for a design with reasonable margin to allow for manufacturing variation. Occasionally, components that meet basic specifications can cause the system to fail IEEE testing because of interactions with other components or the printed circuit board itself. Carefully qualifying new magnetics modules prevents this problem.

When using discrete magnetics it is necessary to use 'Bob Smith' termination: Use four 75  $\Omega$  resistors for cable-side center taps and unused pins. This method terminates pair-to-pair common mode impedance of the CAT5 cable.

Use an EFT capacitor attached to the termination plane. Suggested values are 1500 pF/2 KV or 1000 pF/3 KV. A minimum of 50-mil spacing from capacitor to traces and components should be maintained.

#### 12.1.2 Magnetics Module Qualification Steps

The steps involved in magnetics module qualification are similar to those for crystal qualification:

1. Verify that the vendor's published specifications in the component datasheet meet or exceed specifications.
2. Independently measure the component's electrical parameters on the test bench, checking samples from multiple lots. Check that the measured behavior is consistent from sample to sample and that measurements meet the published specifications.
3. Perform physical layer conformance testing and EMC (FCC and EN) testing in real systems. Vary temperature and voltage while performing system level tests.

#### 12.1.3 Discrete/Integrated Magnetics Specifications

**Table 12-1 Discrete/Integrated Magnetics Specifications**

| Criteria          | Condition                     | Values (Min/Max) |
|-------------------|-------------------------------|------------------|
| Voltage Isolation | At 50 to 60 Hz for 60 seconds | 1500 Vrms (min)  |
|                   | For 60 seconds                | 2250 V dc (min)  |

**Table 12-1 Discrete/Integrated Magnetics Specifications**

|                                                  |                                                                                                                                                                                                                                  |                                                                |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| Open Circuit Inductance (OCL) or OCL (alternate) | With 8 mA DC bias at 25 °C                                                                                                                                                                                                       | 400 $\mu$ H (min)                                              |
|                                                  | With 8 mA DC bias at 0 °C to 70 °C                                                                                                                                                                                               | 350 $\mu$ H (min)                                              |
| Insertion Loss                                   | 100 kHz through 999 kHz                                                                                                                                                                                                          | 1 dB (max)                                                     |
|                                                  | 1.0 MHz through 60 MHz                                                                                                                                                                                                           | 0.6 dB (max)                                                   |
|                                                  | 60.1 MHz through 80 MHz                                                                                                                                                                                                          | 0.8 dB (max)                                                   |
|                                                  | 80.1 MHz through 100 MHz                                                                                                                                                                                                         | 1.0 dB (max)                                                   |
|                                                  | 100.1 MHz through 125 MHz                                                                                                                                                                                                        | 2.4 dB (max)                                                   |

## 12.1.5 Layout Considerations for the Ethernet Interface

The following sections provide recommendations for performing printed circuit board layouts. Good layout practices are essential to meet IEEE PHY conformance specifications and EMI regulatory requirements.

Critical signal traces should be kept as short as possible to decrease the likelihood of being affected by high frequency noise from other signals, including noise carried on power and ground planes. Keeping the traces as short as possible can also reduce capacitive loading.

Since the transmission line medium extends onto the printed circuit board, special attention must be paid to layout and routing of the differential signal pairs.

Designing for 1000 BASE-T Gigabit operation is very similar to designing for 10 and 100 Mb/s. For the I350, system level tests should be performed at all three speeds.

### 12.1.5.1 Guidelines for Component Placement

Component placement can affect signal quality, emissions, and component operating temperature. This section provides guidelines for component placement.

Careful component placement can:

- Decrease potential problems directly related to electromagnetic interference (EMI), which could cause failure to meet applicable government test specifications.
- Simplify the task of routing traces. To some extent, component orientation will affect the complexity of trace routing. The overall objective is to minimize turns and crossovers between traces.

Minimizing the amount of space needed for the Ethernet LAN interface is important because other interfaces compete for physical space on a motherboard near the connector. The Ethernet LAN circuits need to be as close as possible to the connector.

**Figure 12-1 General Placement Distances for 1000 BASE-T Designs**

Figure 12-1 shows some basic placement distance guidelines. Figure 12-1 shows two differential pairs, but can be generalized for a Gigabit system with four analog pairs. The ideal placement for the Ethernet silicon would be approximately one inch behind the magnetics module.

While it is generally a good idea to minimize lengths and distances, Figure 12-1 also illustrates the need to keep the LAN silicon away from the edge of the board and the magnetics module for best EMI performance.

### 12.1.5.2 Layout Guidelines for Use with Integrated and Discrete Magnetics

Layout requirements are slightly different when using discrete magnetics.

These include:

- Ground cut for HV isolation (not required for integrated magnetics)
- A maximum of two (2) vias
- Turns less than 45°
- Discrete terminators

Figure 12-2 shows a reference layout for discrete magnetics.

**Figure 12-2** Layout for Discrete Magnetics

### 12.1.5.3 Board Stack-Up Recommendations

Printed circuit boards for these designs typically have four, six, eight, or more layers. Although, the I350 does not dictate the stack up, here is an example of a typical six-layer board stack up:

- Layer 1 is a signal layer. It can contain the differential analog pairs from the Ethernet device to the magnetics module, or to an optical transceiver.
- Layer 2 is a signal ground layer. Chassis ground may also be fabricated in Layer 2 under the connector side of the magnetics module.
- Layer 3 is used for power planes.
- Layer 4 is a signal layer.
- Layer 5 is an additional ground layer.
- Layer 6 is a signal layer. For 1000 BASE-T (copper) Gigabit designs, it is common to route two of the differential pairs (per port) on this layer.

This board stack up configuration can be adjusted to conform to specific OEM design rules.

### 12.1.5.4 Differential Pair Trace Routing for 10/100/1000 Designs

Trace routing considerations are important to minimize the effects of crosstalk and propagation delays on sections of the board where high-speed signals exist. Signal traces should be kept as short as possible to decrease interference from other signals, including those propagated through power and ground planes. Observe the following suggestions to help optimize board performance:

- Maintain constant symmetry and spacing between the traces within a differential pair.
- Minimize the difference in signal trace lengths of a differential pair.
- Keep the total length of each differential pair under 4 inches. Although possible, designs with differential traces longer than 5 inches are much more likely to have degraded receive BER (Bit Error Rate) performance, IEEE PHY conformance failures, and/or excessive EMI (Electromagnetic Interference) radiation.
- Keep differential pairs more than seven times the dielectric thickness away from each other and other traces, including NVM traces and parallel digital traces.
- Keep maximum separation within differential pairs to 7 mils.
- For high-speed signals, the number of corners and vias should be kept to a minimum. If a 90° bend is required, it is recommended to use two 45° bends instead. Refer to [Figure 12-3](#).

**Note:** In manufacturing, vias are required for testing and troubleshooting purposes. The via size should be a 17-mil ( $\pm 2$  mils for manufacturing variance) finished hole size (FHS).

- Traces should be routed away from board edges by a distance greater than the trace height above the reference plane. This allows the field around the trace to couple more easily to the ground plane rather than to adjacent wires or boards.
- Do not route traces and vias under crystals or oscillators. This will prevent coupling to or from the clock. And as a general rule, place traces from clocks and drives at a minimum distance from apertures by a distance that is greater than the largest aperture dimension.

**Figure 12-3 Trace Routing**

- The reference plane for the differential pairs should be continuous and low impedance. It is recommended that the reference plane be either ground or 1.9 V dc (the voltage used by the PHY). This provides an adequate return path for and high frequency noise currents.
- Do not route differential pairs over splits in the associated reference plane as it may cause discontinuity in impedances.

## 12.1.5.5 Maximum Trace Lengths Based on Trace Geometry

**Table 12-3 Maximum Trace Lengths Based on Trace Geometry and Board Stack-Up**

| Dielectric Thickness (mils) | Dielectric Constant (DK) at 1 MHz | Width / Space / Width (mils) | Pair-to-Pair Space (mils) | Nominal Impedance (Ohms) | Impedance Tolerance (±%) | Maximum Trace Length (inches) <sup>1</sup> |
|-----------------------------|-----------------------------------|------------------------------|---------------------------|--------------------------|--------------------------|--------------------------------------------|
| 2.7                         | 4.05                              | 4/10/4                       | 19                        | 95 <sup>2</sup>          | 17 <sup>2</sup>          | 3.5                                        |
| 2.7                         | 4.05                              | 4/10/4                       | 19                        | 95 <sup>2</sup>          | 15 <sup>2</sup>          | 4                                          |
| 2.7                         | 4.05                              | 4/10/4                       | 19                        | 95                       | 10                       | 5                                          |
| 3.3                         | 4.1                               | 4.2/9/4.2                    | 23                        | 100 <sup>2</sup>         | 17 <sup>2</sup>          | 4                                          |
| 3.3                         | 4.1                               | 4.2/9/4.2                    | 23                        | 100                      | 15                       | 4.6                                        |
| 3.3                         | 4.1                               | 4.2/9/4.2                    | 23                        | 100                      | 10                       | 6                                          |
| 4                           | 4.2                               | 5/9/5                        | 28                        | 100 <sup>2</sup>         | 17 <sup>2</sup>          | 4.5                                        |
| 4                           | 4.2                               | 5/9/5                        | 28                        | 100                      | 15                       | 5.3                                        |
| 4                           | 4.2                               | 5/9/5                        | 28                        | 100                      | 10                       | 7                                          |
| 4                           | 4.2                               | 5/7/5                        | 28                        | 95                       | 10                       | 5.4                                        |
| 4                           | 4.2                               | 5/7/5                        | 28                        | 95                       | 15                       | 4.8                                        |
| 4                           | 4.2                               | 5/7/5                        | 28                        | 95                       | 17                       | 4.3                                        |

**Note:**

1. Longer MDI trace lengths may be achievable, but may make it more difficult to achieve IEEE conformance. Simulations have shown deviations are possible if traces are kept short. Longer traces are possible; use cost considerations and stack-up tolerance for differential pairs to determine length requirements.
2. Deviations from 100  $\Omega$  nominal and/or tolerances greater than 15% decrease the maximum length for IEEE conformance.

Use the MDI Differential Trace Calculator to determine the maximum MDI trace length for your trace geometry and board stack-up. Contact your Intel representative for access.

The following factors can limit the maximum MDI differential trace lengths for IEEE conformance:

- Dielectric thickness
- Dielectric constant
- Nominal differential trace impedance
- Trace impedance tolerance
- Copper trace losses
- Additional devices, such as switches, in the MDI path may impact IEEE conformance.

Board geometry should also be factored in when setting trace length.

**Figure 12-4 MDI Trace Geometry**

### 12.1.5.6 Signal Termination and Coupling

The I350 has internal termination on the MDI signals. External resistors are not needed. Adding pads for external resistors can degrade signal integrity.

### 12.1.5.7 Signal Trace Geometry for 1000 BASE-T Designs

The key factors in controlling trace EMI radiation are the trace length and the ratio of trace-width to trace-height above the reference plane. To minimize trace inductance, high-speed signals and signal layers that are close to a reference or power plane should be as short and wide as practical. Ideally, this trace width to height above the ground plane ratio is between 1:1 and 3:1. To maintain trace impedance, the width of the trace should be modified when changing from one board layer to another if the two layers are not equidistant from the neighboring planes.

Each pair of signal should have a differential impedance of 100  $\Omega$ . +/- 15%. If a particular tool cannot design differential traces, it is permissible to specify 55-65  $\Omega$  single-ended traces as long as the spacing between the two traces is minimized. As an example, consider a differential trace pair on Layer 1 that is 8 mils (0.2 mm) wide and 2 mils (0.05 mm) thick, with a spacing of 8 mils (0.2 mm). If the fiberglass layer is 8 mils (0.2 mm) thick with a dielectric constant,  $E_r$ , of 4.7, the calculated single-ended impedance would be approximately 61  $\Omega$  and the calculated differential impedance would be approximately 100  $\Omega$ .

When performing a board layout, do not allow the CAD tool auto-router to route the differential pairs without intervention. In most cases, the differential pairs will have to be routed manually.

**Note:** Measuring trace impedance for layout designs targeting 100  $\Omega$  often results in lower actual impedance. Designers should verify actual trace impedance and adjust the layout accordingly. If the actual impedance is consistently low, a target of 105 – 110  $\Omega$  should compensate for second order effects.

It is necessary to compensate for trace-to-trace edge coupling, which can lower the differential impedance by up to 10  $\Omega$ , when the traces within a pair are closer than 30 mils (edge to edge).

### 12.1.5.8 Trace Length and Symmetry for 1000 BASE-T Designs

As indicated earlier, the overall length of differential pairs should be less than four inches measured from the Ethernet device to the magnetics.

The differential traces (within each pair) should be equal in total length to within 30 mils (0.76 mm) and as symmetrical as possible. Asymmetrical and unequal length traces in the differential pairs contribute to common mode noise. If a choice has to be made between matching lengths and fixing symmetry, more emphasis should be placed on fixing symmetry. Common mode noise can degrade the receive circuit's performance and contribute to radiated emissions.

#### 12.1.5.8.1 Signal Detect

Each port of the I350 has a signal detect pin for connection to optical transceivers. For designs without optical transceivers, these signals can be left unconnected because they have internal pull-up resistors. Signal detect is not a high-speed signal and does not require special layout.

### 12.1.5.9 Impedance Discontinuities

Impedance discontinuities cause unwanted signal reflections. Minimize vias (signal through holes) and other transmission line irregularities. If vias must be used, a reasonable budget is two per differential trace. Unused pads and stub traces should also be avoided.

### 12.1.5.10 Reducing Circuit Inductance

Traces should be routed over a continuous reference plane with no interruptions. If there are vacant areas on a reference or power plane, the signal conductors should not cross the vacant area. This causes impedance mismatches and associated radiated noise levels. Noisy logic grounds should be separated from analog signal grounds to reduce coupling. Noisy logic grounds can sometimes affect sensitive DC subsystems such as analog to digital conversion, operational amplifiers, etc.

All ground vias should be connected to every ground plane; and similarly, every power via, to all power planes at equal potential. This helps reduce circuit inductance. Another recommendation is to physically locate grounds to minimize the loop area between a signal path and its return path. Rise and fall times should be as slow as possible. Because signals with fast rise and fall times contain many high frequency harmonics, which can radiate significantly. The most sensitive signal returns closest to the chassis ground should be connected together. This will result in a smaller loop area and reduce the likelihood of crosstalk. The effect of different configurations on the amount of crosstalk can be studied using electronics modeling software.

### 12.1.5.11 Signal Isolation

To maintain best signal integrity, keep digital signals far away from the analog traces. A good rule of thumb is no digital signal should be within 300 mils (7.5 mm) of the differential pairs. If digital signals on other board layers cannot be separated by a ground plane, they should be routed perpendicular to the differential pairs. If there is another LAN controller on the board, take care to keep the differential pairs from that circuit away.

Some rules to follow for signal isolation:

- Separate and group signals by function on separate layers if possible. Keep a minimum distance between differential pairs more than seven times the dielectric thickness away from each other and other traces, including NVM traces and parallel digital traces.
- Physically group together all components associated with one clock trace to reduce trace length and radiation.
- Isolate I/O signals from high-speed signals to minimize crosstalk, which can increase EMI emission and susceptibility to EMI from other signals.
- Avoid routing high-speed LAN traces near other high-frequency signals associated with a video controller, cache controller, processor, or other similar devices.

### 12.1.5.12 Traces for Decoupling Capacitors

Traces between decoupling and I/O filter capacitors should be as short and wide as practical. Long and thin traces are more inductive and would reduce the intended effect of decoupling capacitors. Also for similar reasons, traces to I/O signals and signal terminations should be as short as possible. Vias to the decoupling capacitors should be sufficiently large in diameter to decrease series inductance.

### 12.1.5.13 Light Emitting Diodes for Designs Based on the I350

The I350 provides three programmable high-current push-pull (active high) outputs to directly drive LEDs for link activity and speed indication. Each LAN device provides an independent set of LED outputs; these pins and their function are bound to a specific LAN device. Each of the four LED outputs can be individually configured to select the particular event, state, or activity, which is indicated on that output. In addition, each LED can be individually configured for output polarity, as well as for blinking versus non-blinking (steady-state) indication.

Since the LEDs are likely to be integral to a magnetics module, take care to route the LED traces away from potential sources of EMI noise. In some cases, it may be desirable to attach filter capacitors.

The LED ports are fully programmable through the NVM interface.

## 12.1.6 Physical Layer Conformance Testing

Physical layer conformance testing (also known as IEEE testing) is a fundamental capability for all companies with Ethernet LAN products. PHY testing is the final determination that a layout has been performed successfully. If your company does not have the resources and equipment to perform these tests, consider contracting the tests to an outside facility.

### 12.1.6.1 Conformance Tests for 10/100/1000 Mb/s Designs

Crucial tests are as follows, listed in priority order:

- Bit Error Rate (BER). Good indicator of real world network performance. Perform bit error rate testing with long and short cables and many link partners. The test limit is  $10^{-11}$  errors.
- Output Amplitude, Rise and Fall Time (10/100 Mb/s), Symmetry and Droop (1000Mbps). For the 82575 controller, use the appropriate PHY test waveform.
- Return Loss. Indicator of proper impedance matching, measured through the RJ-45 connector back toward the magnetics module.
- Jitter Test (10/100 Mb/s) or Unfiltered Jitter Test (1000 Mb/s). Indicator of clock recovery ability (master and slave for Gigabit controller).

### 12.1.7 Troubleshooting Common Physical Layout Issues

The following is a list of common physical layer design and layout mistakes in LAN On Motherboard Designs.

1. Lack of symmetry between the two traces within a differential pair. Asymmetry can create common-mode noise and distort the waveforms. For each component and/or via that one trace encounters, the other trace should encounter the same component or a via at the same distance from the Ethernet silicon.
2. Unequal length of the two traces within a differential pair. Inequalities create common-mode noise and will distort the transmit or receive waveforms.
3. Excessive distance between the Ethernet silicon and the magnetics. Long traces on FR4 fiberglass epoxy substrate will attenuate the analog signals. In addition, any impedance mismatch in the traces will be aggravated if they are longer than the four inch guideline.
4. Routing any other trace parallel to and close to one of the differential traces. Crosstalk getting onto the receive channel will cause degraded long cable BER. Crosstalk getting onto the transmit channel can cause excessive EMI emissions and can cause poor transmit BER on long cables. At a minimum, other signals should be kept 0.3 inches from the differential traces.
5. Routing one pair of differential traces too close to another pair of differential traces. After exiting the Ethernet silicon, the trace pairs should be kept 0.3 inches or more away from the other trace pairs. The only possible exceptions are in the vicinities where the traces enter or exit the magnetics, the RJ-45 connector, and the Ethernet silicon.
6. Use of a low-quality magnetics module.
7. Re-use of an out-of-date physical layer schematic in a Ethernet silicon design. The terminations and decoupling can be different from one PHY to another.
8. Incorrect differential trace impedances. It is important to have  $\sim 100 \Omega$  impedance between the two traces within a differential pair. This becomes even more important as the differential traces become longer. To calculate differential impedance, many impedance calculators only multiply the single-ended impedance by two. This does not take into account edge-to-edge capacitive coupling between the two traces. When the two traces within a differential pair are kept close to each other, the edge coupling can lower the effective differential impedance by  $5 \Omega$  to  $20 \Omega$ . Short traces have fewer problems if the differential impedance is slightly off target.

## 12.2 PCIe

The controller connects to the host system using a PCIe interface. The interface can be configured to operate in several link modes. These are detailed in the functional description chapter. A link between the ports of two devices is a collection of lanes. Each lane has to be AC-coupled between its corresponding transmitter and receiver; with the AC-coupling capacitor located close to the transmitter side (within 1 inch). Each end of the link is terminated on the die into nominal 100 differential DC impedance. Board termination is not required.

Refer to the *PCI Express\* Base Specification, Revision 2.0* and *PCI Express\* Card Electromechanical Specification, Revision 2.0*.

### 12.2.1 Link Width Configuration

The device supports link widths of x4, x2, or x1 as determined by the PCIe PHY Auto Configuration Structure. The configuration is loaded into the Maximum Link Width field of the PCIe capability Register (LCAP[11:6]; with the silicon default of a x4 link).

During link configuration, the platform and the controller negotiate a common link width. In order for this to work, the selected maximum number of PCIe lanes must be connected to the host system.

### 12.2.2 Polarity Inversion and Lane Reversal

To ease routing, designers have the flexibility to the lane reversal modes supported by the I350. Polarity inversion can also be used, since the polarity of each differential pair is detected during the link training sequence.

When lane reversal is used, some of the down-shift options are not available. For a description of available combinations, consult the functional description in the PCIe interconnects chapter of this document.

### 12.2.3 PCIe Reference Clock

The device requires a 100 MHz differential reference clock, denoted PE\_CLK\_p and PE\_CLK\_n. This signal is typically generated on the system board and routed to the PCIe port. For add-in cards, the clock will be furnished at the PCIe connector.

The frequency tolerance for the PCIe reference clock is +/- 300 ppm.

## 12.3 Clock Source

All designs require a 25 MHz clock source. The I350 uses the 25 MHz source to generate clocks up to 125 MHz and 1.25 GHz for the PHY circuits. For optimum results with lowest cost, connect a 25 MHz parallel resonant crystal and appropriate load capacitors at the XTAL1 and XTAL2 leads. The frequency tolerance of the timing device should be 30 ppm or better.

Refer to the [Intel® Ethernet Controllers Timing Device Selection Guide](#) for more information on choosing crystals. For further information regarding the clock for the I350, refer to the sections about frequency control, crystals, and oscillators that follow.

### 12.3.1 Frequency Control Device Design Considerations

This section provides information regarding frequency control devices, including crystals and oscillators, for use with all Intel Ethernet controllers. Several suitable frequency control devices are available; none of which present any unusual challenges in selection. The concepts documented herein are applicable to other data communication circuits, including Platform LAN Connect devices (PHYs).

The Intel Ethernet controllers contain amplifiers, which when used with the specific external components, form the basis for feedback oscillators. These oscillator circuits, which are both economical and reliable, are described in more detail in [Section 12.4.1](#).

The Intel Ethernet controllers also have bus clock input functionality, however a discussion of this feature is beyond the scope of this document, and will not be addressed.

The chosen frequency control device vendor should be consulted early in the design cycle. Crystal and oscillator manufacturers familiar with networking equipment clock requirements may provide assistance in selecting an optimum, low-cost solution.

### 12.3.2 Frequency Control Component Types

Several types of third-party frequency reference components are currently marketed. A discussion of each follows, listed in preferred order.

#### 12.3.2.1 Quartz Crystal

Quartz crystals are generally considered to be the mainstay of frequency control components due to their low cost and ease of implementation. They are available from numerous vendors in many package types and with various specification options.

#### 12.3.2.2 Fixed Crystal Oscillator

A packaged fixed crystal oscillator comprises an inverter, a quartz crystal, and passive components conveniently packaged together. The device renders a strong, consistent square wave output. Oscillators used with microprocessors are supplied in many configurations and tolerances.

Crystal oscillators should be restricted to use in special situations, such as shared clocking among devices or multiple controllers. As clock routing can be difficult to accomplish, it is preferable to provide a separate crystal for each device.

### 12.3.2.3 Programmable Crystal Oscillators

A programmable oscillator can be configured to operate at many frequencies. The device contains a crystal frequency reference and a phase lock loop (PLL) clock generator. The frequency multipliers and divisors are controlled by programmable fuses.

A programmable oscillator's accuracy depends heavily on the Ethernet device's differential transmit lines. The Physical Layer (PHY) uses the clock input from the device to drive a differential Manchester (for 10 Mb/s operation), an MLT-3 (for 100 Mbps operation) or a PAM-5 (for 1000 Mbps operation) encoded analog signal across the twisted pair cable. These signals are referred to as self-clocking, which means the clock must be recovered at the receiving link partner. Clock recovery is performed with another PLL that locks onto the signal at the other end.

PLLs are prone to exhibit frequency jitter. The transmitted signal can also have considerable jitter even with the programmable oscillator working within its specified frequency tolerance. PLLs must be designed carefully to lock onto signals over a reasonable frequency range. If the transmitted signal has high jitter and the receiver's PLL loses its lock, then bit errors or link loss can occur.

PHY devices are deployed for many different communication applications. Some PHYs contain PLLs with marginal lock range and cannot tolerate the jitter inherent in data transmission clocked with a programmable oscillator. The American National Standards Institute (ANSI) X3.263-1995 standard test method for transmit jitter is not stringent enough to predict PLL-to-PLL lock failures, therefore, the use of programmable oscillators is not recommended.

### 12.3.2.4 Ceramic Resonator

Similar to a quartz crystal, a ceramic resonator is a piezoelectric device. A ceramic resonator typically carries a frequency tolerance of  $\pm 0.5\%$ , – inadequate for use with Intel Ethernet controllers, and therefore, should not be utilized.

## 12.4 Crystal Support

### 12.4.1 Crystal Selection Parameters

All crystals used with Intel Ethernet controllers are described as AT-cut, which refers to the angle at which the unit is sliced with respect to the long axis of the quartz stone. [Table 12-4](#) lists crystals which have been used successfully in other designs (however, no particular product is recommended):

**Table 12-4 Crystal Manufacturers and Part Numbers**

| Manufacturer          | Part No.                              |
|-----------------------|---------------------------------------|
| KDS America           | DSX321G                               |
| NDK America Inc.      | 41CD25.0F1303018                      |
| TXC Corporation - USA | 7A25000165 <sup>1</sup><br>9C25000008 |

1. This part footprint compatible with X540 designs.

For information about crystal selection parameters, see the electrical specification.

### 12.4.1.1 Vibrational Mode

Crystals in the above-referenced frequency range are available in both fundamental and third overtone. Unless there is a special need for third overtone, use fundamental mode crystals.

At any given operating frequency, third overtone crystals are thicker and more rugged than fundamental mode crystals. Third overtone crystals are more suitable for use in military or harsh industrial environments. Third overtone crystals require a trap circuit (extra capacitor and inductor) in the load circuitry to suppress fundamental mode oscillation as the circuit powers up. Selecting values for these components is beyond the scope of this document.

### 12.4.1.2 Nominal Frequency

Intel Ethernet controllers use a crystal frequency of 25.000 MHz. The 25 MHz input is used to generate a 125 MHz transmit clock for 100BASE-TX and 1000BASE-TX operation – 10 MHz and 20 MHz transmit clocks, for 10BASE-T operation.

### 12.4.1.3 Frequency Tolerance

The frequency tolerance for an Ethernet Platform LAN Connect is dictated by the IEEE 802.3 specification as  $\pm 50$  parts per million (ppm). This measurement is referenced to a standard temperature of 25° C. Intel recommends a frequency tolerance of  $\pm 30$  ppm.

### 12.4.1.4 Temperature Stability and Environmental Requirements

Temperature stability is a standard measure of how the oscillation frequency varies over the full operational temperature range (and beyond). Several optional temperature ranges are currently available, including -40° C to +85° C for industrial environments. Some vendors separate operating temperatures from temperature stability. Manufacturers may also list temperature stability as 50 ppm in their data sheets.

**Note:** Crystals also carry other specifications for storage temperature, shock resistance, and reflow solder conditions. Crystal vendors should be consulted early in the design cycle to discuss the application and its environmental requirements.

### 12.4.1.5 Calibration Mode

The terms series-resonant and parallel-resonant are often used to describe crystal oscillator circuits. Specifying parallel mode is critical to determining how the crystal frequency is calibrated at the factory.

A crystal specified and tested as series resonant oscillates without problem in a parallel-resonant circuit, but the frequency is higher than nominal by several hundred parts per million. The purpose of adding load capacitors to a crystal oscillator circuit is to establish resonance at a frequency higher than the crystal's inherent series resonant frequency.

Figure 12-5 shows the recommended placement and layout of an internal oscillator circuit. Note that pin X1 and X2 refers to XTAL1 and XTAL2 in the Ethernet device, respectively. The crystal and the capacitors form a feedback element for the internal inverting amplifier. This combination is called parallel-resonant, because it has positive reactance at the selected frequency. In other words, the crystal behaves like an inductor in a parallel LC circuit. Oscillators with piezoelectric feedback elements are also known as “Pierce” oscillators.

### 12.4.1.6 Load Capacitance

The formula for crystal load capacitance is as follows:

$$C_L = \frac{(C1 \cdot C2)}{(C1 + C2)} + C_{stray}$$

where  $C1 = C2 = 27 \text{ pF}$

and  $C_{stray}$  = allowance for additional capacitance in pads, traces and the chip carrier within the Ethernet device package

An allowance of 3 pF to 7 pF accounts for lumped stray capacitance. The calculated load capacitance is 16 pF with an estimated stray capacitance of about 5 pF.

Individual stray capacitance components can be estimated and added. For example, surface mount pads for the load capacitors add approximately 2.5 pF in parallel to each capacitor. This technique is especially useful if Y1, C1 and C2 must be placed farther than approximately one-half (0.5) inch from the device. It is worth noting that thin circuit boards generally have higher stray capacitance than thick circuit boards. Consult the PCIe Design Guide for more information.

The oscillator frequency should be measured with a precision frequency counter where possible. The load specification or values of C1 and C2 should be fine tuned for the design. As the actual capacitance load increases, the oscillator frequency decreases.

**Note:** C1 and C2 may vary by as much as 5% (approximately 1 pF) from their nominal values.

### 12.4.1.7 Shunt Capacitance

The shunt capacitance parameter is relatively unimportant compared to load capacitance. Shunt capacitance represents the effect of the crystal's mechanical holder and contacts. The shunt capacitance should equal a maximum of 6 pF.

### 12.4.1.8 Equivalent Series Resistance

Equivalent Series Resistance (ESR) is the real component of the crystal's impedance at the calibration frequency, which the inverting amplifier's loop gain must overcome. ESR varies inversely with frequency for a given crystal family. The lower the ESR, the faster the crystal starts up. Use crystals with an ESR value of 50  $\Omega$  or better.

### 12.4.1.9 Drive Level

Drive level refers to power dissipation in use. The allowable drive level for a Surface Mounted Technology (SMT) crystal is less than its through-hole counterpart, because surface mount crystals are typically made from narrow, rectangular AT strips, rather than circular AT quartz blanks.

Some crystal data sheets list crystals with a maximum drive level of 1 mW. However, Intel Ethernet controllers drive crystals to a level less than the suggested 0.3 mW value. This parameter does not have much value for on-chip oscillator use.

### 12.4.1.10 Aging

Aging is a permanent change in frequency (and resistance) occurring over time. This parameter is most important in its first year because new crystals age faster than old crystals. Use crystals with a maximum of  $\pm 5$  ppm per year aging.

### 12.4.1.11 Reference Crystal

The normal tolerances of the discrete crystal components can contribute to small frequency offsets with respect to the target center frequency. To minimize the risk of tolerance-caused frequency offsets causing a small percentage of production line units to be outside of the acceptable frequency range, it is important to account for those shifts while empirically determining the proper values for the discrete loading capacitors, C1 and C2.

Even with a perfect support circuit, most crystals will oscillate slightly higher or slightly lower than the exact center of the target frequency. Therefore, frequency measurements (which determine the correct value for C1 and C2) should be performed with an ideal reference crystal. When the capacitive load is exactly equal to the crystal's load rating, an ideal reference crystal will be perfectly centered at the desired target frequency.

#### 12.4.1.11.1 Reference Crystal Selection

There are several methods available for choosing the appropriate reference crystal:

- If a Saunders and Associates (S&A) crystal network analyzer is available, then discrete crystal components can be tested until one is found with zero or nearly zero ppm deviation (with the appropriate capacitive load). A crystal with zero or near zero ppm deviation will be a good reference crystal to use in subsequent frequency tests to determine the best values for C1 and C2.
- If a crystal analyzer is not available, then the selection of a reference crystal can be done by measuring a statistically valid sample population of crystals, which has units from multiple lots and approved vendors. The crystal, which has an oscillation frequency closest to the center of the distribution, should be the reference crystal used during testing to determine the best values for C1 and C2.
- It may also be possible to ask the approved crystal vendors or manufacturers to provide a reference crystal with zero or nearly zero deviation from the specified frequency when it has the specified CLoad capacitance.

When choosing a crystal, customers must keep in mind that to comply with IEEE specifications for 10/100 and 10/100/1000Base-T Ethernet LAN, the transmitter reference frequency must be precise within  $\pm 50$  ppm. Intel® recommends customers to use a transmitter reference frequency that is accurate to within  $\pm 30$  ppm to account for variations in crystal accuracy due to crystal manufacturing tolerance.

#### 12.4.1.11.2 Circuit Board

Since the dielectric layers of the circuit board are allowed some reasonable variation in thickness, the stray capacitance from the printed board (to the crystal circuit) will also vary. If the thickness tolerance for the outer layers of dielectric are controlled within  $\pm 17$  percent of nominal, then the circuit board should not cause more than  $\pm 2$  pF variation to the stray capacitance at the crystal. When tuning crystal frequency, it is recommended that at least three circuit boards are tested for frequency. These boards should be from different production lots of bare circuit boards.

Alternatively, a larger sample population of circuit boards can be used. A larger population will increase the probability of obtaining the full range of possible variations in dielectric thickness and the full range of variation in stray capacitance.

Next, the exact same crystal and discrete load capacitors (C1 and C2) must be soldered onto each board, and the LAN reference frequency should be measured on each circuit board.

The circuit board, which has a LAN reference frequency closest to the center of the frequency distribution, should be used while performing the frequency measurements to select the appropriate value for C1 and C2.

#### 12.4.1.11.3 Temperature Changes

Temperature changes can cause the crystal frequency to shift. Therefore, frequency measurements should be done in the final system chassis across the system's rated operating temperature range.

## 12.4.2 Crystal Placement and Layout Recommendations

Crystal clock sources should not be placed near I/O ports or board edges. Radiation from these devices can be coupled into the I/O ports and radiate beyond the system chassis. Crystals should also be kept away from the Ethernet magnetics module to prevent interference.

**Note:** Failure to follow these guidelines could result in the 25 MHz clock failing to start.

When designing the layout for the crystal circuit, the following rules must be used:

- Place load capacitors as close as possible (within design-for-manufacturability rules) to the crystal solder pads. They should be no more than 90 mils away from crystal pads.
- The two load capacitors, crystal component, the Ethernet controller device, and the crystal circuit traces must all be located on the same side of the circuit board (maximum of one via-to-ground load capacitor on each XTAL trace).
- Use 27 pF (5% tolerance) 0402 load capacitors.
- Place load capacitor solder pad directly in line with circuit trace (see [Figure 12-5](#), point A).
- Use 50  $\Omega$  impedance single-ended microstrip traces for the crystal circuit.
- Route traces so that electro-magnetic fields from XTAL2 do not couple onto XTAL1. No differential traces.
- Route XTAL1 and XTAL2 traces to nearest inside corners of crystal pad (see [Figure 12-5](#), point B).
- Ensure that the traces from XTAL1 and XTAL2 are symmetrically routed and that their lengths are matched.
- The total trace length of XTAL1 or XTAL2 should be less than 750 mils.

**Figure 12-5 Recommended Crystal Placement and Layout**

## 12.5 Oscillator Support

The I350 clock input circuit is optimized for use with an external crystal. However, an oscillator can also be used in place of the crystal with the proper considerations:

- We recommend adding an AC decoupling capacitor between the oscillator output and the input (XTAL1) of the LAN device.
- The input clock jitter from the oscillator can impact the I350 clock and its performance.

**Note:** The power consumption of additional circuitry equals about 1.5 mW.

Table 12-5 lists oscillators that can be used with the controller. Please note that no particular oscillator is recommended).

**Table 12-5 Oscillator Manufacturers and Part Numbers**

| Manufacturer             | Part No.                 |
|--------------------------|--------------------------|
| NDK AMERICA INC          | 2560TKA-25M              |
| TXC CORPORATION - USA    | 6N25000160 or 7W25000025 |
| CITIZEN AMERICA CORP     | CSX750FJB25.000M-UT      |
| Raltron Electronics Corp | CO4305-25.000-T-TR       |
| MtronPTI                 | M214TCN                  |
| Kyocera Corporation      | KC5032C-C3               |

**Figure 12-6 Oscillator Solution**

## 12.5.1 Oscillator Placement and Layout Recommendations

Oscillator clock sources should not be placed near I/O ports or board edges. Radiation from these devices can be coupled into the I/O ports and radiate beyond the system chassis. Oscillators should also be kept away from the Ethernet magnetics module to prevent interference.

## 12.6 Device Disable

For a LOM design, it might be desirable for the system to provide BIOS-setup capability for selectively enabling or disabling LOM devices. This enables designers more control over system resource-management, avoid conflicts with add-in NIC solutions, etc. The I350 provides support for selectively enabling or disabling it.

Device disable is initiated by asserting the asynchronous DEV\_OFF\_N pin. The DEV\_OFF\_N pin has an internal pull-up resistor, so that it can be left not connected to enable device operation.

The NVM's *Device Disable Power Down En* bit enables device disable mode (hardware default is that the mode is disabled).

While in device disable mode, the PCIe link is in L3 state. The PHY is in power down mode. Output buffers are tri-stated.

Assertion or deassertion of PCIe PE\_RST\_N does not have any effect while the I350 is in device disable mode (that is, the I350 stays in the respective mode as long as DEV\_OFF\_N is asserted). However, the I350 might momentarily exit the device disable mode from the time PCIe PE\_RST\_N is de-asserted again and until the NVM is read.

During power-up, the DEV\_OFF\_N pin is ignored until the NVM is read. From that point, the I350 might enter device disable if DEV\_OFF\_N is asserted.

**Note:** The DEV\_OFF\_N pin should maintain its state during system reset and system sleep states. It should also insure the proper default value on system power up. For example, a designer could use a GPIO pin that defaults to 1b (enable) and is on system suspend power. For example, it maintains the state in S0-S5 ACPI states).

### 12.6.1 BIOS Handling of Device Disable

Assume that in the following power-up sequence the DEV\_OFF\_N signal is driven high (or it is already disabled)

1. The PCIe is established following the GIO\_PWR\_GOOD.
2. BIOS recognizes that the entire I350 should be disabled.
3. The BIOS drives the DEV\_OFF\_N signal to the low level.
4. As a result, the I350 samples the DEV\_OFF\_N signals and enters either the device disable mode.
5. The BIOS could put the link in the Electrical IDLE state (at the other end of the PCIe link) by clearing the *Link Disable* bit in the Link Control register.
6. BIOS might start with the device enumeration procedure (the entire I350 functions are invisible).
7. Proceed with normal operation

Re-enable could be done by driving high the DEV\_OFF\_N signal, followed later by bus enumeration.

## 12.7 SMBus and NC-SI

SMBus and NC-SI are interfaces for pass-through and configuration traffic between the Management Controller (MC) and the device.

**Note:** Intel recommends that the SMBus be connected to the ICH or MC for the EEPROM recovery solution. If the connection is to a MC, it will be able to send the EEPROM release command.

The I350 can be connected to an external MC. It operates in one of two modes:

- SMBus mode
- NC-SI mode

The Clock-out (if enabled) is provided in all power states (unless the device is disabled).

**Figure 12-7 External MC Connections with NC-SI and SMBus**

## **12.8 NC-SI**

### **12.8.1 Design Requirements**

#### **12.8.1.1 Network Controller**

The NC-SI Interface enables network manageability implementations required by information technology personnel for remote control and alerting via the LAN. Management packets can be routed to or from a management processor.

#### **12.8.1.2 External Management Controller (MC)**

An external MC is required to meet the requirements called out in the latest NC-SI specification as it relates to this interface.

#### **12.8.1.3 Reference Schematic**

The following reference schematic (provides connectivity requirements for single and multi-drop applications. This configuration only has a single connection to the MC. The network device also supports multi-drop NC-SI configuration architecture with software arbitration support from the management controller.

See the NC-SI specification for connectivity requirements for multi-drop applications.

**Figure 12-8 NC-SI Connection Schematic: Single-Drop Configuration**

**Figure 12-9 NC-SI Connection Schematic: Multi-Drop Configuration**

## 12.8.2 Layout Requirements

### 12.8.2.1 Board Impedance

The NC-SI signaling interface is a single ended signaling environment and as such Intel recommends a target board and trace impedance of 50 Ohms plus 20% and minus 10%. This impedance ensures optimal signal integrity and quality.

### 12.8.2.2 Trace Length Restrictions

The recommended maximum trace lengths for each circuit board application is dependent on the number drops and the total capacitive loading from all the trace segments on each NC-SI signal net. The number via's must also be considered. Circuit board material variations and trace etch process variations affect the trace impedance and trace capacitance. For each fixed design, highest trace capacitance occurs when trace impedance is lowest. For the FR4 board stack-up provided in direct connect applications, the maximum length for a 50 ohm NC-SI trace would be approximately 9 inches on a minus 10% board impedance skew. This ensures that signal integrity and quality are preserved and enables the design to comply with NC-SI electrical requirements.

For special applications which require longer NC-SI traces, the total functional NC-SI trace length can be extended with non-compliant rise time by:

- providing good clock and signal alignment
- testing with the target receiver to verify it meets setup and hold requirements.

For multi-drop applications, the total capacitance and the extra resistive loading affect the rise time. A multi-drop of two devices limits the total length to 8 inches. A multi-drop of four limits the total length to 6.5 inches. Capacitive loading of extra via's have a nominal effect on the total load.

**Figure 12-10 NC-SI Trace Length Requirement for Direct Connect**

Table 12-6 shows how 7 more vias increase the rise time by 0.5ns. Again, longer trace lengths can be achieved.

**Table 12-6 Stack Up, 7 Vias**

| Item                 | Value | Units   |
|----------------------|-------|---------|
| Trace width          | 4.5   | mils    |
| Trace thickness      | 1.9   | mils    |
| Dielectric thickness | 3.0   | mils    |
| Dielectric constant  | 4.1   | --      |
| Loss Tangent         | 0.024 | --      |
| Nominal Impedance    | 50    | Ohms    |
| Trace Capacitance    | 1.39  | pf/inch |

Table 12-7 shows example trace lengths for the multi-drop topology of two and four represented in the figures that follow.

**Table 12-7 Example Trace Lengths for Multi-Drop Topologies, 2 & 4**

| Multi-drop length parameter used in Figure 12-11 and Figure 12-12 . | Segment length example for multi drop configurations |                        |                         |                        |
|---------------------------------------------------------------------|------------------------------------------------------|------------------------|-------------------------|------------------------|
|                                                                     | Two drop configuration                               |                        | Four drop configuration |                        |
|                                                                     | Length (Inches)                                      | Trace capacitance (Pf) | Length (Inches)         | Trace capacitance (Pf) |
| L1                                                                  | 2                                                    | 2.8                    | 1.5                     | 8.8                    |
| L2                                                                  | 4                                                    | 5.6                    | 2                       | 16.1                   |
| L3                                                                  | 2                                                    | 2.8                    | 1                       | 8.1                    |
| Total                                                               | 8                                                    | 11.1                   | 6.5                     | 35.6                   |

**Figure 12-11 Example 2-Drop Topology**

### Figure 12-12 Example 4-Drop Topology

**Table 12-8 Compliant NC-SI Maximum Length on a 50 ohm -10% Skew-board with Example Stack-up.**

| Topology       | Total maximum compliant linear bus size (inches) | Number of vias | Approximate Net trace capacitance minus load capacitance (pf) |
|----------------|--------------------------------------------------|----------------|---------------------------------------------------------------|
| 4 multi-drop   | 6.0                                              | 1              | 8.3                                                           |
| 4 multi-drop   | 5.5                                              | 8              | 8.3                                                           |
| 2 multi-drop   | 8.0                                              | 1              | 11.1                                                          |
| 2 multi-drop   | 7.5                                              | 8              | 11.1                                                          |
| Point to point | 9.0                                              | 1              | 12.5                                                          |
| Point to point | 8.5                                              | 8              | 12.5                                                          |

Extending NC-SI to a maximum 11ns rise time increases the maximum trace length.

§ §

## 13 Thermal Management

---

This chapter provides methods for determining the operating temperature in a system based on case temperature. Case temperature is a function of the local ambient and internal temperatures of the component.

Properly designed solutions provide adequate cooling to maintain case temperature (T<sub>case</sub>) at or below what is listed in [Table 13-2](#). This is accomplished by providing a low local ambient temperature, airflow, and creating a minimal thermal resistance to that local ambient temperature. Heatsinks and higher airflow may be required if temperatures exceed those listed.

### 13.1 Thermal Sensor and Thermal Diode

The I350 has both an on board thermal sensor and a thermal diode. The thermal sensor is read using the PCIe interface, the NC-SI interface, or the SMBUS interface.

The thermal diode can be read by forcing 1mA of current through the thermal diode and measuring the voltage.

The junction temperature can be determined from the following equations:

$$\begin{aligned} &17 \times 17 \text{mm Package} \\ &T_j = -695.834 * V_d + 657.277 \end{aligned}$$

$$\begin{aligned} &25 \times 25 \text{mm Package} \\ &T_j = -696.5785 * V_d + 657.7948 \end{aligned}$$

$\Delta V$  the voltage drop on the diode when 1mA forced

The thermal sensor and the thermal diode are not located in the same part of the die. In some situations, there can be up to a 7°C difference between the measurement on the thermal sensor and the measurement on the diode. The difference is most significant when the PCIe interface is enabled but the BASE-T interface is disabled.

See the figure below for approximate positioning.

**Figure 13-1** Approximate Location of Sensor and Diodes

## 13.2 Thermal Design Considerations

In a system, the temperature of a component is a function of both the system and component thermal characteristics. System-level thermal constraints consist of the local ambient temperature at the component, the airflow over the component and surrounding board, and the physical constraints surrounding the component that may limit the size of a thermal enhancement (heat sink).

A component's case/die temperature depends on:

- component power dissipation
- size
- packaging materials (effective thermal conductivity)
- type of interconnection to the substrate and motherboard
- presence of a thermal cooling solution
- power density of the substrate, nearby components, and motherboard

These parameters are pushed by the continued trend of technology to increase performance levels (higher operating speeds, MHz) and power density (more transistors). As operating frequencies increase and packaging size decreases, power density increases and the thermal cooling solution space and airflow become more constrained. The result is an increased emphasis on system design to ensure that thermal design requirements are met for each component in the system.

**Note:** Operation outside the functional limit can degrade system performance, cause logic errors, or cause device and/or system damage. Temperatures exceeding the maximum operating limits may result in irreversible changes in the device operating characteristics. Sustained operation at component maximum temperature limit may affect long-term device reliability.

## 13.3 Terminology

The following terminology is used in this chapter:

- **PBGA Plastic Ball Grid Array:** A surface-mount package using a BGA structure whose PCB-interconnect method consists of Pb-free solder ball array on the interconnect side of the package and attached to a plastic substrate material. An integrated heat spreader (**IHS**) may be present for larger PBGA packages for enhanced thermal performance (but IHS is not present for the I350).
- **Junction:** Refers to a P-N junction on the silicon. In this document, it is used as a temperature reference point (for example,  $\Theta_{JA}$  refers to the “junction” to “ambient” thermal resistance).
- **Ambient:** Refers to local ambient temperature of the bulk air approaching the component. It can be measured by placing a thermocouple approximately 1” inch upstream from the component edge.
- **Lands:** The pads on the PCB to which BGA balls are soldered.
- **PCB:** Printed circuit board.
- **Printed Circuit Assembly (PCA):** An assembled PCB.
- **Thermal Design Power (TDP):** The estimated maximum possible/expected power generated in a component by a realistic application. Use Maximum power requirements listed in [Table 13-2](#).
- **LFM:** Linear feet per minute (airflow).
- **$\Theta_{JA}$  (Theta JA):** Thermal resistance junction-to-ambient, °C/W.
- **$\Psi_{JT}$  (Psi JT):** Junction-to-top (of package) thermal characterization parameter, °C/W.  $\Psi_{JT}$  does not represent thermal resistance, but instead is a characteristic parameter that can be used to convert between  $T_j$  and  $T_{case}$  when knowing the total TDP.  $\Psi_{JT}$  is easy to characterize in simulations or measurements, and is equal to  $T_j$  minus  $T_{case}$  divided by the total TDP. This parameter can vary by environment conditions like heat sink and airflow.

## 13.4 Thermal Specifications

The thermal solution must maintain a case temperature at or below the values specified in [Table 13-2](#). System-level or component-level thermal enhancements are required to dissipate the generated heat to ensure the case temperature never exceeds the maximum temperatures listed. [Table 13-1](#) lists the thermal performance parameters per JEDEC JESD51-2 standard.

In [Table 13-1](#), the  $\Theta_{JA}$  values should be used as reference only and can vary by system environment.  $\Psi_{JT}$  values also can vary by system environment. They are given in [Table 13-1](#) as the maximum value for I350 simulations.

Analysis indicates that real applications are unlikely to cause the I350 to be at  $T_{case-max}$  for sustained periods of time, given that  $T_{case}$  can reasonably be expected to be a distribution of temperatures. Sustained operation at  $T_{case-max}$  may affect long-term reliability of the I350 and the system; sustained operation at  $T_{case-max}$  should be evaluated during the thermal design process and steps taken to further reduce the  $T_{case}$  temperature.

Good system airflow is critical to dissipate the highest possible thermal power. The size and number of fans, vents, and/or ducts, and, their placement in relation to components and airflow channels within the system determine airflow. Acoustic noise constraints may limit the size and types of fans, vents and ducts that can be used in a particular design.

To develop a reliable, cost-effective thermal solution, all of the system variables must be considered. Use system-level thermal characteristics and simulations to account for individual component thermal requirements.

**Table 13-1 Package Thermal Characteristics in Standard JEDEC Environment**

| Package                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | $\Theta_{JA}$ (°C/W) | $\Psi_{JT}$ (°C/W) |

| <b>Notes:</b><br>1. Power value shown in Table 2 is measured maximum power, also known as Thermal Design Power (TDP). TDP is a system design target associated with the maximum component operating temperature specifications. Maximum power values are determined based on typical DC electrical specification and maximum ambient temperature for a worst-case realistic application running at maximum utilization.<br>2. Tcase Max-hs is defined as the maximum case temperature with the Default Enhanced Thermal Solution attached.<br>3. This is a not to exceed maximum allowable case temperature. |                               |                                             |

The thermal parameters defined above are based on simulated results of packages assembled on standard multi layer 2s2p 1.0-oz Cu layer boards in a natural convection environment. The maximum case temperature is based on the maximum junction temperature and defined by the relationship, maximum Tcase = Tjmax - ( $\Psi_{JT}$  x Power) where  $\Psi_{JT}$  is the junction-to-top (of package) thermal characterization parameter. If the case temperature exceeds the specified Tcase max, thermal enhancements such as heat sinks or forced air will be required.  $\Theta_{JA}$  is the thermal resistance junction-to-ambient of the package.

## 13.4.1 Case Temperature

The I350 is designed to operate properly as long as Tcase rating is not exceeded. Section 6.1 discusses proper guidelines for measuring the case temperature.

## 13.5 Thermal Attributes

### 13.5.1 Designing for Thermal Performance

Section 13.10, “Heatsink and Attach Suppliers” and Section 13.11, “PCB Guidelines” document the PCB and system design recommendations required to achieve I350 thermal performance.

### 13.5.2 Typical System Definition

A system with the following attributes was used to generate thermal characteristics data:

- A heatsink case, see [Section 13.6.2, “Default Enhanced Thermal Solution”](#).
- A JEDEC JESD 51-9 standard 2s2p Board.

Keep the following in mind when reviewing the data that is included in this document:

- All data is preliminary and is not validated against physical samples.
- Your system design may be significantly different.
- A larger board (more than six copper layers) may improve I350 thermal performance.

### 13.5.3 Package Mechanical Attributes

For information on package attributes, see [Chapter 11, “Electrical/Mechanical Specification”](#).

### 13.5.4 Package Thermal Characteristics

See the table for an aid in determining the optimum airflow and heatsink combination for the I350. The table shows Tcase as a function of airflow and ambient temperature at the Thermal Design Power (TDP) for a typical system. Your system design may vary. Flotherm\* models are available upon request. Contact your local Intel representative.

**Table 13-3 Expected Tcase (°C) for Five Heat Sinks at 4.0 W (JEDEC Card)**

| Case Temperature (Max = 111C) |    |               |       |       |       |       |       |       |       |       |

**Note:** The Red blocked value(s) indicate airflow/ambient combinations that exceed the allowable case temperature for the I350 line at 4.0 W.

## 13.6 Thermal Enhancements

One method used to improve thermal performance is to increase the device surface area by attaching a metallic heatsink to the component top. Increasing the surface area of the heatsink reduces the thermal resistance from the heatsink to the air, increasing heat transfer.

### 13.6.1 Clearances

To be effective, a heatsink should have a pocket of air around it that is free of obstructions.

### 13.6.2 Default Enhanced Thermal Solution

If you have no control over the end-user's thermal environment or if you wish to bypass the thermal modeling and evaluation process, use the default solutions (see Section 13.6.2, "Default Enhanced Thermal Solution"). These solutions replicate the performance defined in [Table 13-3](#) at Thermal Design Power (TDP). If after implementing the Recommended Enhanced Thermal Solution, the case temperature continues to exceed allowable values additional cooling is needed. This additional cooling may be achieved by improving airflow to the component and/or adding additional thermal enhancements.

### 13.6.3 Extruded Heatsinks

If required, the following extruded heatsinks are the suggested. [Figure 13-2](#) through [Figure 13-6](#) shows the multiple profiles.

| Width | Length | Height | Fin Thickness Across Width | Fin Thickness Across Length | Base Thickness | # of fins across width | # of fins across length |
|-------|--------|--------|----------------------------|-----------------------------|----------------|------------------------|-------------------------|
| 27mm  | 27mm   | 10mm   | 0.90mm                     | 0.93mm                      | 1.50mm         | 12                     | 13                      |

## 13.6.4 Attaching the Extruded Heatsink

An extruded heatsink may be attached using clips with a phase change thermal interface material. For attaching methods, contact the heatsink manufacturer.

### 13.6.4.1 Clips

A well-designed clip, in conjunction with a thermal interface material (tape, grease, etc.) often offers the best combination of mechanical stability and reworkability. Use of a clip requires significant advance planning as mounting holes are required in the PCB.

### 13.6.4.2 Thermal Interface (PCM45 Series)

The recommended thermal interface is the PCM45 series from Honeywell. PCM45 Series thermal interface pads are phase change materials formulated for use in high performance devices requiring minimum thermal resistance for maximum heat sink performance and component reliability. These pads consist of an electrically non-conductive, dry film that softens at device operating temperatures resulting in "greasy-like" performance. However, Intel has not fully validated the PCM45 Series TIM.

Each PCA, system and heatsink combination varies in attach strength. Carefully evaluate the reliability of double sided thermal interface tape attachments prior to high-volume use (see Section 5.5).

### 13.6.4.3 Maximum Static Normal Load

Maximum applied pressure should not exceed 20 psi.

**Note:** The PWB under the component must be fully supported to prevent bowing or flexing of the PWB.

The force must be applied perpendicular to the component.

The pressure needs to be evenly distributed on the top side of the component.

### 13.6.5 Reliability

Each PCA, system and heatsink combination varies in attach strength and long-term adhesive performance. Evaluate the reliability of the completed assembly prior to high-volume use. Reliability recommendations are in [Table 13-4](#).

**Table 13-4 Reliability Validation**

| Test <sup>1</sup>     | Requirement                                                                      | Pass/Fail Criteria <sup>2</sup> |
|-----------------------|----------------------------------------------------------------------------------|---------------------------------|
| Mechanical Shock      | 50G trapezoidal, board level<br>11 ms, 3 shocks/axis                             | Visual and Electrical Check     |
| Random Vibration      | 7.3G, board level<br>45 minutes/axis, 50 to 2000 Hz                              | Visual and Electrical Check     |
| High-Temperature Life | 85 °C<br>2000 hours total<br>Checkpoints occur at 168, 500, 1000, and 2000 hours | Visual and Mechanical Check     |
| Thermal Cycling       | Per-Target Environment<br>(for example: -40 °C to +85 °C)<br>500 Cycles          | Visual and Mechanical Check     |
| Humidity              | 85% relative humidity<br>85 °C, 1000 hours                                       | Visual and Mechanical Check     |

**Notes:**

1. Performed the above tests on a sample size of at least 12 assemblies from 3 lots of material (total = 36 assemblies).
2. Additional pass/fail criteria can be added at your discretion.

## 13.7 Thermal Interface Management for Heat-Sink Solutions

To optimize heatsink design, it is important to understand the interface between the silicon die and the heatsink base. Thermal conductivity effectiveness depends on the following:

- Bond line thickness
- Interface material area
- Interface material thermal conductivity

### 13.7.1 Bond Line Management

The gap between the silicon die and the heatsink base impacts heat-sink solution performance. The larger the gap between the two surfaces, the greater the thermal resistance. The thickness of the gap is determined by the flatness of the heatsink base, the silicon die, and the package encapsulant, plus the thickness of the thermal interface material (for example, PSA, thermal grease, epoxy) used to join the two surfaces.

### 13.7.2 Interface Material Performance

The following factors impact the performance of the interface material between the silicon die and the heatsink base:

- Thermal resistance of the material
- Wetting/filling characteristics of the material

#### 13.7.2.1 Thermal Resistance of the Material

Thermal resistance describes the ability of the thermal interface material to transfer heat from one surface to another. The higher the thermal resistance, the less efficient the heat transfer. The thermal resistance of the interface material has a significant impact on the thermal performance of the overall thermal solution. The higher the thermal resistance, the larger the temperature drop required across the interface.

#### 13.7.2.2 Wetting/Filling Characteristics of the Material

The wetting/filling characteristic of the thermal interface material is its ability to fill the gap between the package's top surface and the heatsink. Since air is an extremely poor thermal conductor, the more completely the interface material fills the gaps, the lower the temperature-drop across the interface, increasing the efficiency of the thermal solution.

## 13.8 Measurements for Thermal Specifications

Determining the thermal properties of the system requires careful case temperature measurements. Guidelines for measuring the I350 case temperature are provided in [Section 6.3](#).

### 13.8.1 Case Temperature Measurements

Maintain Tcase at or below the maximum case temperatures listed in [Table 13-2](#) to ensure functionality and reliability. Special care is required when measuring the Tcase temperature to ensure an accurate temperature measurement. Use the following guidelines when making Tcase measurements:

- Measure the surface temperature of the case in the geometric center of the case top.
- Calibrate the thermocouples used to measure Tcase before making temperature measurements.
- Use 36-gauge (maximum) K-type thermocouples.

Care must be taken to avoid introducing errors into the measurements when measuring a surface temperature that is a different temperature from the surrounding local ambient air. Measurement errors may be due to a poor thermal contact between the thermocouple junction and the surface of the package, heat loss by radiation, convection, conduction through thermocouple leads, and/or contact between the thermocouple cement and the heat-sink base (if used).

#### 13.8.1.1 Attaching the Thermocouple (No Heatsink)

The following approach is recommended to minimize measurement errors for attaching the thermocouple with no heatsink:

- Use 36-gauge or smaller-diameter K-type thermocouples.
- Ensure that the thermocouple has been properly calibrated.
- Attach the thermocouple bead or junction to the top surface of the package (case) in the center of the heat spreader using high thermal conductivity cements.

**Note:** It is critical that the entire thermocouple lead be butted tightly to the heat spreader.

Attach the thermocouple at a 0° angle if there is no interference with the thermocouple attach location or leads (see [Figure 13-3](#)). This is the preferred method and is recommended for use with packages not having a heat sink.

**Figure 13-7** Technique for Measuring Tcase with 0° Angle Attachment, No Heatsink

### 13.8.1.2 Attaching the Thermocouple (Heatsink)

The following approach is recommended to minimize measurement errors for attaching the thermocouple with heatsink:

- Use 36-gauge or smaller diameter K-type thermocouples.
- Ensure that the thermocouple is properly calibrated.
- Attach the thermocouple bead or junction to the case's top surface in the geometric center using a high thermal conductivity cement.

**Note:** It is critical that the entire thermocouple lead be butted tightly against the case.

- Attach the thermocouple at a 90° angle if there is no interference with the thermocouple attach location or leads (see [Figure 13-4](#)). This is the preferred method and is recommended for use with packages with heatsinks.
- For testing purposes, a hole (no larger than 0.150" in diameter) must be drilled vertically through the center of the heatsink to route the thermocouple wires out.
- Ensure there is no contact between the thermocouple cement and heatsink base. Any contact affects the thermocouple reading.

**Figure 13-8** Technique for Measuring Tcase with 90° Angle Attachment

## 13.9 Thermal Diode

The I350 incorporates an on-die diode that may be used to monitor the die temperature (junction temperature). A thermal sensor located on the motherboard or a stand-alone measurement kit, may monitor the die temperature of the I350 for thermal management or characterization.

## 13.10 Heatsink and Attach Suppliers

**Table 13-5 Heatsink and Attach Suppliers**

| Part                       | Part Number                       | Supplier            | Contact                                                                                                                                                                  |

## 13.11 PCB Guidelines

The following general PCB design guidelines are recommended to maximize the thermal performance of PBGA packages:

- When connecting ground (thermal) vias to the ground planes, do not use thermal-relief patterns.
- Thermal-relief patterns are designed to limit heat transfer between the vias and the copper planes, thus constricting the heat flow path from the component to the ground planes in the PCB.
- As board temperature also has an effect on the thermal performance of the package, avoid placing the I350 adjacent to high-power dissipation devices.
- If airflow exists, locate the components in the mainstream of the airflow path for maximum thermal performance. Avoid placing the components downstream, behind larger devices or devices with heat sinks that obstruct the air flow or supply excessively heated air.

**Note:** The above information is provided as a general guideline to help maximize the thermal performance of the components.

## 14 Diagnostics

### 14.1 JTAG Test Mode Description

The I350 includes a JTAG (TAP) port compliant with the IEEE Standard Test Access Port and Boundary Scan Architecture 1149.6 Specification.

The TAP controller is accessed serially through the four dedicated pins TCK, TMS, TDI, and TDO. TMS, TDI, and TDO operate synchronously with TCK which is independent of all other clock within the I350. This interface can be used for test and debug purposes. System board interconnects can be DC tested using the boundary scan logic in pads. [Table 14-1](#) shows TAP controller related pin descriptions. [Table 14-2](#) describes the TAP instructions supported by the I350. The default instruction after JTAG reset is IDCODE.

**Table 14-1 TAP Controller Pins**

| Signal | I/O | Description                                                                                                                                                                                             |
|--------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCK    | In  | Test clock input for the test logic defined by IEEE1149.1.<br>Note: Signal should be connected to ground through a 1 k $\Omega$ pull-down resistor.                                                     |
| TDI    | In  | Test Data Input. Serial test instructions and data are received by the test logic at this pin.<br>Note: Signal should be connected to VCC33 through a 1 k $\Omega$ pull-up resistor.                    |
| TDO    | O/D | Test Data Output. The serial output for the test instructions and data from the test logic defined in IEEE1149.1.<br>Note: Signal should be connected to VCC33 through a 1 k $\Omega$ pull-up resistor. |
| TMS    | In  | Test Mode Select input. The signal received at TMS is decoded by the TAP controller to control test operations.<br>Note: Signal should be connected to VCC33 through a 1 k $\Omega$ pull-up resistor.   |

**Table 14-2 TAP Instructions Supported**

| Instruction | Description                                                                                                                                                                                                                  | Comment                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| BYPASS      | The BYPASS command selects the Bypass Register, a single bit register connected between TDI and TDO pins. This allows more rapid movement of test data to and from other components in the system.                           | IEEE 1149.1 Std. Instruction |
| EXTEST      | The EXTEST Instruction allows circuitry or wiring external to the devices to be tested. Boundary-scan Register Cells at outputs are used to apply stimulus while Boundary-scan cells at input pins are used to capture data. | IEEE 1149.1 Std. Instruction |

**Table 14-2 TAP Instructions Supported (Continued)**

| Instruction         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Comment                      |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| SAMPLE /<br>PRELOAD | <p>The SAMPLE/PRELOAD instruction is used to allow scanning of the boundary scan register without causing interference to the normal operation of the device. Two functions can be performed by use of the Sample/Preload instruction.</p> <p>SAMPLE – allows a snapshot of the data flowing into and out of a device to be taken without affecting the normal operation of the device.</p> <p>PRELOAD – allows an initial pattern to be placed into the boundary scan register cells. This allows initial known data to be present prior to the selection of another boundary-scan test operation.</p> | IEEE 1149.1 Std. Instruction |
| IDCODE              | <p>The IDCODE instruction is forced into the parallel output latches of the instruction register during the Test-Logic-Reset TAP state. This allows the device identification register to be selected by manipulation of the broadcast TMS and TCK signals for testing purposes, as well as by a conventional instruction register scan operation.</p> <p>The ID code value for the I350 A0 is 0x0151F013 (Intel's Vendor ID = 0x13, Device ID = 0x151F, Rev ID = 0x0)</p> <p>The ID code value for the I350 A1 is 0x1151F013 (Intel's Vendor ID = 0x13, Device ID = 0x151F, Rev ID = 0x1)</p>          | IEEE 1149.1 Std. Instruction |
| HIGHZ               | <p>The HIGHZ instruction is used to force all outputs of the device (except TDO) into a high impedance state. This instruction shall select the Bypass Register to be connected between TDI and TDO in the Shift-DR controller state.</p>                                                                                                                                                                                                                                                                                                                                                               | IEEE 1149.1 Std. Instruction |

## Appendix A Changes from 82580

**Note:** This appendix summarizes changes in I350 relative to 82580.

**Table A-1 Changes in the Programming Interface Relative to 82580**

| Feature | Registers/Descriptors      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Dummy function changes | PCIe capability Structures       | Dummy function changes: <ul style="list-style-type: none"> <li>Command register - I/O access enable and Memory Access Enable are R/W. Interrupt Disable field is RO as one.</li> <li>PCI Power Management Capability (0x40) - Next pointer is 0xA0 to skip MSI/MSI-X.</li> <li>Power Management Capabilities (0x42)- PME_Support is RO 0.</li> <li>CSR Access Via Configuration Address Space (0x98/0x9C) not available for dummy functions.</li> <li>MSI/MSI-X/VPD capabilities not available for dummy functions.</li> <li>PCI Express Capability Register (0xA0) - next pointer is 0x00 to skip VPD.</li> <li>Device Capabilities 2 (0xC4) - Completion Timeout Disable Supported - set to RO 0b.</li> <li>Device Control 2 (0xC8) - Completion Timeout Value and Completion Timeout Disable are RO zero.</li> <li>PCIe Extended Capability Structure for dummy is AER -&gt; ARI (if enabled) -&gt; ACS.</li> <li>Serial Number/SR-IOV/TPH/LTR not available in Dummy function.</li> </ul> |
| Other PCIe changes     | PCIe capability Structures       | <ul style="list-style-type: none"> <li>Default Device ID is now 0x151F.</li> <li>Added ACS capability (0x1D0 and 0x1D4)</li> <li>Modified "Next Capability pointer" fields (Bits 31:20) in AER, Serial ID, ARI, TPH and LTR capabilities to reflect the new link list options.</li> <li>Added support for ID-ordering (0xC8).</li> <li>Modified AER Capability Version field (bits 19:16) to 0x2 in "PCIe CAP ID" (0x100; RO).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                        | PMCSR                            | Changed default value of No_Soft_Reset bit (bit 3) in PMCSR to 1, to meet PCIe Specification recommendations for MFD (Multi-function Devices).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| IDO support            | Device Control 2                 | Added IDO related fields to PCIe Device Control 2 register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ASPM Optionality       | Link Capabilities                | Added "ASPM Optionality Compliance" bit (bit 22) to the "Link Capabilities" Register (0xAC; RO)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DMA Coalescing         | DMCRTRH                          | Renamed DMCRTRH.LRPRCW to DMCRTRH.LRPRPW to indicate that low rate was detected in previous window and not in current window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                        | DMACR                            | <ul style="list-style-type: none"> <li>Added move to "deepest Lx" mode (value 11b) to DMACR.DMAC_Lx field. Default value of field changed to 11b.</li> <li>Added DC_LPBKW_EN (bit 14), DC_BMC2OSW_EN (bit 15), DC_FLUSH (bit 24) and EXIT_DC (bit 25) to DMACR register.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                        | DMCTLX                           | Added DC_FLUSH (bit 30) and DCFLUSH_DIS (bit 31) to the DMCTLX register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Other registers        | PSRTYPE and RPLPSRTYPE registers | Added to PSRTYPE and RPLPSRTYPE the capability to split on MAC header only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                        | LVMMC                            | Added to the LVMMC register the VLAN IERR bit (bit 26). Added LVMMC.MVF_MACC bit (bit 19) to indicate that memory access initiated by VF terminated with an Unsupported Request (UR) or Completer Abort (CA).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                        | WUC                              | APM wake-up is disabled in D0. If APM wake-up is required software should not disable APM wake in WUC register on entry to D0, to allow for APM wake on system crash.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                        | DTXCTL                           | Changed default value of SPOOF_INT bit (bit 6) to 0b and removed OutOfSyncEnable bit (bit 4).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                        | STATUS                           | Added STATUS.PF_RST_DONE bit to indicate that internal reset sequence completed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                        | BARCTRL                          | Changed address of BARCTRL register to 0x5BFC from 0x5BBC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Other registers        | SWSM                             | Added SWMB_CLR bit (bit 31) to the SWSM register to reset the SWMBWR, SWMB0, SWMB1, SWMB2 and SWMB3 Software Mailbox registers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table A-1 Changes in the Programming Interface Relative to 82580 (Continued)**

| Feature                       | Registers/Descriptors                                                      | Description                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Flash and EEPROM              | FLA                                                                        | <ul style="list-style-type: none"> <li>Changed FLA_ABORT bit (bit 7) to read only and added FLA_CLR_ERR bit (bit 8) to FLA register.</li> <li>Added FL_BAR_WR bit (bit 29) to the FLA register to indicate occurrence of Flash write or Erase access via direct memory (BAR) access.</li> <li>Updated Flash Write Flow in <a href="#">Section 3.3.4.2</a>.</li> </ul>     |
|                               | EEC                                                                        | <ul style="list-style-type: none"> <li>Changed EE_BLOCKED bit (bit 15) and EE_ABORT bit (bit 16) to Read Only and added EE_CLR_ERR bit (bit 18) to EEC register.</li> <li>Added EEC.EE_DET bit (bit 19) to indicate detection of EEPROM</li> <li>Added EEC.EE_RD_TIMEOUT bit (bit 17) to indicate read abort when executing EEPROM read via the EERD register.</li> </ul> |
|                               | EEARBC                                                                     | Added VALID_PCIE bit (bit 3) to "EEPROM Auto Read Bus Control - EEARBC (0x1024; R/W)" register to enable write to PCIe PHY EEPROM bits.                                                                                                                                                                                                                                   |
|                               | EEMNGCTL                                                                   | Added EEMNGCTL_CLR_ERR bit (bit 29) and TIMEOUT bit (bit 30) to EEMNGCTL register.                                                                                                                                                                                                                                                                                        |
| Interrupts                    | ICR, ICS, IMS and IMC                                                      | <ul style="list-style-type: none"> <li>Renamed bit DOU5YNC (bit 28) to MDDET (Malicious Driver Detect) in ICR, ICS, IMS and IMC registers.</li> <li>Added the Thermal Sensor Event (TS) interrupt bit (bit 23) to the ICR, ICS, IMS and IMC registers.</li> </ul>                                                                                                         |
| Manageability Changes         | MDEF/MDEF_EXT registers                                                    | Added two MAC addresses to the AND and OR sections.<br>Added MDEF_EXT.APPLY_to_host_traffic bit.                                                                                                                                                                                                                                                                          |
|                               | MANC                                                                       | Added EN_BMC2NET bit.<br>Modified description of RCV_TCO_EN bit.<br>Changed the "TCO Reset" bit (bit 16) and "FW Reset" bit (bit 14) in the MANC register to R/W1C.                                                                                                                                                                                                       |
|                               | host interface                                                             | Modified failover command to support 4 ports (relative to 82576).                                                                                                                                                                                                                                                                                                         |

|                       | PHY Identifier Register 2                                                                                                                              | Changed the PHY "Manufactures Module Number" in the "PHY Identifier Register 2 (MSB) - PHY ID 2 (03d; RO)" PHY register to 0x3B.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                       | EMIADD and EMIDATA                                                                                                                                     | Added EMIADD (address 16d) and EMIDATA (address 17d) registers to enable access of registers in extended PHY memory address space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                       | EEE PHY registers in extended PHY address space.                                                                                                       | Added PHY related EEE (IEEE802.3az) in extended PHY memory address space. Can be accessed using EMIADD (address 16d) and EMIDATA (address 17d) registers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| LTR Support           | LTRC                                                                                                                                                   | Added LTRC.EEEMS_EN field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ECC and Parity checks | DTPARC, DTPARS, DPARS, DDPARC, DDPARS, DDECCC, DDECCS, RPBECCSTS, TPBECCSTS, PCIEECCSTS, PCIEECCCTL, PCIEERRSTS, PCIEERRCTL, LANPERRCTL and LANPERRSTS | <ul style="list-style-type: none"> <li>Modified parity/ECC functionality in: <ul style="list-style-type: none"> <li>DTPARC, DTPARS(R/W1C) and DPARS (R/W1C) registers - Register is per function, Status bits are clear by write 1.</li> <li>DDPARC and DDPARS (R/W1C) registers - DHOST Rams have ECC protection. Renamed register to DDECCC and DDECCS. DDECCS is Clear by Write 1b.</li> <li>RPBECCSTS register - Added Loopback Buffer support and "RPBECCSTS.Corr_err_cnt" field was removed.</li> <li>TPBECCSTS register - Added Management TX buffer support and "TPBECCSTS.Corr_err_cnt" field was removed.</li> <li>PCIEECCSTS (R/W1C)- Register logs correctable ECC errors, added Rams that changed protection to ECC.</li> <li>PCIEECCCTL - Added memories that have ECC protection.</li> <li>PCIEERRCTL - Removed memories that previously had parity error detection and now have ECC error detection.</li> <li>PCIEERRCTL - Added Global Parity Enable bit (GPAR_EN). When bit is 0b parity error detection is disabled.</li> <li>PCIEERRSTS (R/W1C)- Removed memories that previously had parity error detection and now have ECC error detection. Register is per function.</li> </ul> </li> <li>Updated behavior description on reception of parity error for the various memories.</li> <li>Added XTX ram bit (enable and status).</li> </ul> |

## Данный компонент на территории Российской Федерации

**Вы можете приобрести в компании MosChip.**

Для оперативного оформления запроса Вам необходимо перейти по данной ссылке:

<http://moschip.ru/get-element>

Вы можете разместить у нас заказ для любого Вашего проекта, будь то серийное производство или разработка единичного прибора.

В нашем ассортименте представлены ведущие мировые производители активных и пассивных электронных компонентов.

Нашей специализацией является поставка электронной компонентной базы двойного назначения, продукции таких производителей как XILINX, Intel (ex.ALTERA), Vicor, Microchip, Texas Instruments, Analog Devices, Mini-Circuits, Amphenol, Glenair.

Сотрудничество с глобальными дистрибьюторами электронных компонентов, предоставляет возможность заказывать и получать с международных складов практически любой перечень компонентов в оптимальные для Вас сроки.

На всех этапах разработки и производства наши партнеры могут получить квалифицированную поддержку опытных инженеров.

Система менеджмента качества компании отвечает требованиям в соответствии с ГОСТ Р ИСО 9001, ГОСТ РВ 0015-002 и ЭС РД 009
