

FEATURES

- Two-Channel Simultaneously Sampling ADC
- 84.1dB SNR (46 μ V_{RMS} Input Referred Noise)
- 99dB SFDR
- ± 2.3 LSB INL(Max)
- Low Power: 160mW Total, 80mW per Channel
- Single 1.8V Supply
- CMOS, DDR CMOS, or DDR LVDS Outputs
- Selectable Input Ranges: 1V_{P-P} to 2.1V_{P-P}
- 200MHz Full Power Bandwidth S/H
- Shutdown and Nap Modes
- Serial SPI Port for Configuration
- Pin Compatible with
 - LTC2180: 16-Bit, 25Msps, 78mW
 - LTC2140-14: 14-Bit, 25Msps, 50mW
- 64-Lead (9mm \times 9mm) QFN Package

APPLICATIONS

- Low Power Instrumentation
- Software Defined Radios
- Portable Medical Imaging
- Multi-Channel Data Acquisition

TYPICAL APPLICATION

DESCRIPTION

The LTC®2270 is a two-channel simultaneous sampling 16-bit A/D converter designed for digitizing high frequency, wide dynamic range signals. It is perfect for demanding applications with AC performance that includes 84.1dB SNR and 99dB spurious free dynamic range (SFDR).

DC specs include ± 1 LSB INL (typ), ± 0.2 LSB DNL (typ) and no missing codes over temperature. The transition noise is 1.44LSB_{RMS}.

The digital outputs can be either full rate CMOS, Double Data Rate CMOS, or Double Data Rate LVDS. A separate output power supply allows the CMOS output swing to range from 1.2V to 1.8V.

The ENC⁺ and ENC⁻ inputs may be driven differentially or single-ended with a sine wave, PECL, LVDS, TTL, or CMOS inputs. An optional clock duty cycle stabilizer allows high performance at full speed for a wide range of clock duty cycles.

ABSOLUTE MAXIMUM RATINGS (Notes 1, 2)

Supply Voltages (V_{DD} , $0V_{DD}$) $-0.3V$ to $2V$
 Analog Input Voltage (A_{IN}^+ , A_{IN}^- ,
 PAR/SER, SENSE) (Note 3) $-0.3V$ to $(V_{DD} + 0.2V)$
 Digital Input Voltage (ENC^+ , ENC^- , \bar{CS} ,
 SDI, SCK) (Note 4) $-0.3V$ to $3.9V$
 SDO (Note 4) $-0.3V$ to $3.9V$

Digital Output Voltage $-0.3V$ to $(0V_{DD} + 0.3V)$
 Operating Temperature Range
 LTC2270C $0^\circ C$ to $70^\circ C$
 LTC2270I $-40^\circ C$ to $85^\circ C$
 Storage Temperature Range $-65^\circ C$ to $150^\circ C$

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: All voltage values are with respect to GND with GND and OGND shorted (unless otherwise noted).

Note 3: When these pin voltages are taken below GND or above V_{DD} , they will be clamped by internal diodes. This product can handle input currents of greater than 100mA below GND or above V_{DD} without latchup.

Note 4: When these pin voltages are taken below GND they will be clamped by internal diodes. When these pin voltages are taken above V_{DD} they will not be clamped by internal diodes. This product can handle input currents of greater than 100mA below GND without latchup.

Note 5: $V_{DD} = 0V$, $V_{DD} = 1.8V$, $f_{SAMPLE} = 20\text{MHz}$, LVDS outputs, differential $ENC^+/ENC^- = 2\text{V}_{\text{P-P}}$ sine wave, input range = $2.1\text{V}_{\text{P-P}}$ with differential drive, unless otherwise noted.

Note 6: Integral nonlinearity is defined as the deviation of a code from a best fit straight line to the transfer curve. The deviation is measured from the center of the quantization band.

Note 7: Offset error is the offset voltage measured from -0.5 LSB when the output code flickers between 0000 0000 0000 0000 and 1111 1111 1111 1111 in 2's complement output mode.

Note 8: Guaranteed by design, not subject to test.

Note 9: $V_{DD} = 1.8V$, $f_{SAMPLE} = 20\text{MHz}$, CMOS outputs, ENC^+ = single-ended 1.8V square wave, $ENC^- = 0V$, input range = $2.1\text{V}_{\text{P-P}}$ with differential drive, 5pF load on each digital output unless otherwise noted. The supply current and power dissipation specifications are totals for the entire IC, not per channel.

Note 10: Recommended operating conditions.

TYPICAL PERFORMANCE CHARACTERISTICS

TYPICAL PERFORMANCE CHARACTERISTICS

PIN FUNCTIONS

PINS THAT ARE THE SAME FOR ALL DIGITAL OUTPUT MODES

V_{DD} (Pins 1, 16, 17, 64): Analog Power Supply, 1.7V to 1.9V. Bypass to ground with 0.1 μ F ceramic capacitors. Adjacent pins can share a bypass capacitor.

V_{CM1} (Pin 2): Common Mode Bias Output, nominally equal to V_{DD}/2. V_{CM1} should be used to bias the common mode of the analog inputs to channel 1. Bypass to ground with a 1 μ F ceramic capacitor.

GND (Pins 3, 6, 14): ADC Power Ground.

A_{IN1}⁺ (Pin 4): Channel 1 Positive Differential Analog Input.

A_{IN1}⁻ (Pin 5): Channel 1 Negative Differential Analog Input.

REFH (Pins 7, 9): ADC High Reference. See the Applications Information section for recommended bypassing circuits for REFH and REFL.

REFL (Pins 8, 10): ADC Low Reference. See the Applications Information section for recommended bypassing circuits for REFH and REFL.

PAR/SER (Pin 11): Programming mode selection pin. Connect to ground to enable the serial programming mode. CS, SCK, SDI, SDO become a serial interface that control the A/D operating modes. Connect to V_{DD} to enable the parallel programming mode where CS, SCK, SDI, SDO become parallel logic inputs that control a reduced set of the A/D operating modes. PAR/SER should be connected directly to ground or V_{DD} and not be driven by a logic signal.

A_{IN2}⁺ (Pin 12): Channel 2 Positive Differential Analog Input.

A_{IN2}⁻ (Pin 13): Channel 2 Negative Differential Analog Input.

V_{CM2} (Pin 15): Common Mode Bias Output, nominally equal to V_{DD}/2. V_{CM2} should be used to bias the common mode of the analog inputs to channel 2. Bypass to ground with a 1 μ F ceramic capacitor.

ENC⁺ (Pin 18): Encode Input. Conversion starts on the rising edge.

ENC⁻ (Pin 19): Encode Complement Input. Conversion starts on the falling edge. Tie to GND for single-ended encode mode.

CS (Pin 20): In serial programming mode, (PAR/SER = 0V), CS is the Serial Interface Chip Select Input. When CS is low, SCK is enabled for shifting data on SDI into the mode control registers. In the parallel programming mode (PAR/SER = V_{DD}), CS controls the clock duty cycle stabilizer (See Table 2). CS can be driven with 1.8V to 3.3V logic.

SCK (Pin 21): In serial programming mode, (PAR/SER = 0V), SCK is the Serial Interface Clock Input. In the parallel programming mode (PAR/SER = V_{DD}), SCK controls the digital output mode. (See Table 2). SCK can be driven with 1.8V to 3.3V logic.

SDI (Pin 22): In serial programming mode, (PAR/SER = 0V), SDI is the Serial Interface Data Input. Data on SDI is clocked into the mode control registers on the rising edge of SCK. In the parallel programming mode (PAR/SER = V_{DD}), SDI can be used together with SDO to power down the part (see Table 2). SDI can be driven with 1.8V to 3.3V logic.

OGND (Pin 41): Output Driver Ground. Must be shorted to the ground plane by a very low inductance path. Use multiple vias close to the pin.

OV_{DD} (Pin 42): Output Driver Supply. Bypass to ground with a 0.1 μ F ceramic capacitor.

SDO (Pin 61): In serial programming mode, (PAR/SER = 0V), SDO is the optional Serial Interface Data Output. Data on SDO is read back from the mode control registers and can be latched on the falling edge of SCK. SDO is an open-drain NMOS output that requires an external 2k pull-up resistor to 1.8V – 3.3V. If read back from the mode control registers is not needed, the pull-up resistor is not necessary and SDO can be left unconnected. In the parallel programming mode (PAR/SER = V_{DD}), SDO can be used together with SDI to power down the part (see Table 2). When used as an input, SDO can be driven with 1.8V to 3.3V logic through a 1k series resistor.

PIN FUNCTIONS

V_{REF} (Pin 62): Reference Voltage Output. Bypass to ground with a $2.2\mu F$ ceramic capacitor. The output voltage is nominally 1.25V.

SENSE (Pin 63): Reference Programming Pin. Connecting SENSE to V_{DD} selects the internal reference and a $\pm 1.05V$ input range. Connecting SENSE to ground selects the internal reference and a $\pm 0.525V$ input range. An external reference between 0.625V and 1.3V applied to SENSE selects an input range of $\pm 0.84 \cdot V_{SENSE}$.

Ground (Exposed Pad Pin 65): The exposed pad must be soldered to the PCB ground.

FULL-RATE CMOS OUTPUT MODE

All Pins Below Have CMOS Output Levels (OGND to OV_{DD})

D2_0 to D2_15 (Pins 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38): Channel 2 Digital Outputs. D2_15 is the MSB.

CLKOUT⁻ (Pin 39): Inverted version of CLKOUT⁺.

CLKOUT⁺ (Pin 40): Data Output Clock. The digital outputs normally transition at the same time as the falling edge of CLKOUT⁺. The phase of CLKOUT⁺ can also be delayed relative to the digital outputs by programming the mode control registers.

D1_0 to D1_15 (Pins 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58): Channel 1 Digital Outputs. D1_15 is the MSB.

OF2 (Pin 59): Channel 2 Over/Under Flow Digital Output. OF2 is high when an overflow or underflow has occurred.

OF1 (Pin 60): Channel 1 Over/Under Flow Digital Output. OF1 is high when an overflow or underflow has occurred.

DOUBLE DATA RATE CMOS OUTPUT MODE

All Pins Below Have CMOS Output Levels (OGND to OV_{DD})

D2_0_1 to D2_14_15 (Pins 24, 26, 28, 30, 32, 34, 36, 38): Channel 2 Double Data Rate Digital Outputs. Two data bits are multiplexed onto each output pin. The even data bits (D0, D2, D4, D6, D8, D10, D12, D14) appear when CLKOUT⁺ is low. The odd data bits (D1, D3, D5, D7, D9, D11, D13, D15) appear when CLKOUT⁺ is high.

DNC (Pins 23, 25, 27, 29, 31, 33, 35, 37, 43, 45, 47, 49, 51, 53, 55, 57, 59): Do not connect these pins.

CLKOUT⁻ (Pin 39): Inverted version of CLKOUT⁺.

CLKOUT⁺ (Pin 40): Data Output Clock. The digital outputs normally transition at the same time as the falling and rising edges of CLKOUT⁺. The phase of CLKOUT⁺ can also be delayed relative to the digital outputs by programming the mode control registers.

D1_0_1 to D1_14_15 (Pins 44, 46, 48, 50, 52, 54, 56, 58): Channel 1 Double Data Rate Digital Outputs. Two data bits are multiplexed onto each output pin. The even data bits (D0, D2, D4, D6, D8, D10, D12, D14) appear when CLKOUT⁺ is low. The odd data bits (D1, D3, D5, D7, D9, D11, D13, D15) appear when CLKOUT⁺ is high.

OF2_1 (Pin 60): Over/Under Flow Digital Output. OF2_1 is high when an overflow or underflow has occurred. The over/under flow for both channels are multiplexed onto this pin. Channel 2 appears when CLKOUT⁺ is low, and Channel 1 appears when CLKOUT⁺ is high.

PIN FUNCTIONS

DOUBLE DATA RATE LVDS OUTPUT MODE

All Pins Below Have LVDS Output Levels. The Output Current Level Is Programmable. There Is an Optional Internal 100Ω Termination Resistor Between the Pins of Each LVDS Output Pair.

D2_0_1-/D2_0_1+ to D2_14_15-/D2_14_15+ (Pins 23/24, 25/26, 27/28, 29/30, 31/32, 33/34, 35/36, 37/38): Channel 2 Double Data Rate Digital Outputs. Two data bits are multiplexed onto each differential output pair. The even data bits (D0, D2, D4, D6, D8, D10, D12, D14) appear when CLKOUT⁺ is low. The odd data bits (D1, D3, D5, D7, D9, D11, D13, D15) appear when CLKOUT⁺ is high.

CLKOUT-/CLKOUT⁺ (Pins 39/40): Data Output Clock. The digital outputs normally transition at the same time as the falling and rising edges of CLKOUT⁺. The phase of

CLKOUT⁺ can also be delayed relative to the digital outputs by programming the mode control registers.

D1_0_1-/D1_0_1+ to D1_14_15-/D1_14_15+ (Pins 43/44, 45/46, 47/48, 49/50, 51/52, 53/54, 55/56, 57/58): Channel 1 Double Data Rate Digital Outputs. Two data bits are multiplexed onto each differential output pair. The even data bits (D0, D2, D4, D6, D8, D10, D12, D14) appear when CLKOUT⁺ is low. The odd data bits (D1, D3, D5, D7, D9, D11, D13, D15) appear when CLKOUT⁺ is high.

OF2_1-/OF2_1+ (Pins 59/60): Over/Under Flow Digital Output. OF2_1⁺ is high when an overflow or underflow has occurred. The over/under flow for both channels are multiplexed onto this pin. Channel 2 appears when CLKOUT⁺ is low, and Channel 1 appears when CLKOUT⁺ is high.

APPLICATIONS INFORMATION

CONVERTER OPERATION

The LTC2270 is a low power, two-channel, 16-bit, 20Msps A/D converter that is powered by a single 1.8V supply. The analog inputs must be driven differentially. The encode input can be driven differentially, or single ended for lower power consumption. The digital outputs can be CMOS, double data rate CMOS (to halve the number of output lines), or double data rate LVDS (to reduce digital noise in the system.) Many additional features can be chosen by programming the mode control registers through a serial SPI port.

ANALOG INPUT

The analog inputs are differential CMOS sample-and-hold circuits (Figure 2). The inputs should be driven differentially around a common mode voltage set by the V_{CM1} or V_{CM2} output pins, which are nominally $V_{DD}/2$. For the 2.1V input range, the inputs should swing from $V_{CM} - 525\text{mV}$ to $V_{CM} + 525\text{mV}$. There should be 180° phase difference between the inputs.

Figure 2. Equivalent Input Circuit. Only One of the Two Analog Channels Is Shown

The two channels are simultaneously sampled by a shared encode circuit (Figure 2).

INPUT DRIVE CIRCUITS

Input filtering

If possible, there should be an RC lowpass filter right at the analog inputs. This lowpass filter isolates the drive circuitry from the A/D sample-and-hold switching, and also limits wideband noise from the drive circuitry. Figure 3 shows an example of an input RC filter. The RC component values should be chosen based on the application's input frequency.

Transformer Coupled Circuits

Figure 3 shows the analog input being driven by an RF transformer with a center-tapped secondary. The center tap is biased with V_{CM} , setting the A/D input at its optimal DC level. At higher input frequencies a transmission line balun transformer (Figure 4 to Figure 5) has better balance, resulting in lower A/D distortion.

Figure 3. Analog Input Circuit Using a Transformer.
Recommended for Input Frequencies from 1MHz to 40MHz

APPLICATIONS INFORMATION

Amplifier Circuits

Figure 6 shows the analog input being driven by a high speed differential amplifier. The output of the amplifier is AC-coupled to the A/D so the amplifier's output common mode voltage can be optimally set to minimize distortion.

If DC coupling is necessary, use a differential amplifier with an output common mode set by the LTC2270 V_{CM} pin (Figure 7).

Figure 5. Recommended Front-End Circuit for Input Frequencies Above 80MHz

Reference

The LTC2270 has an internal 1.25V voltage reference. For a 2.1V input range using the internal reference, connect SENSE to V_{DD} . For a 1.05V input range using the internal reference, connect SENSE to ground. For a 2.1V input range with an external reference, apply a 1.25V reference voltage to SENSE (Figure 9).

The input range can be adjusted by applying a voltage to SENSE that is between 0.625V and 1.30V. The input range will then be $1.68 \cdot V_{SENSE}$.

The V_{REF} , $REFH$ and $REFL$ pins should be bypassed as shown in Figure 8. A low inductance $2.2\mu F$ interdigitated capacitor is recommended for the bypass between $REFH$ and $REFL$. This type of capacitor is available at a low cost from multiple suppliers.

Figure 6. Front-End Circuit Using a High Speed Differential Amplifier

Figure 7. DC-Coupled Amplifier

APPLICATIONS INFORMATION

Figure 8a. Reference Circuit

Alternatively C1 can be replaced by a standard 2.2 μ F capacitor between REFH and REFL (see Figure 8b). The capacitors should be as close to the pins as possible (not on the back side of the circuit board).

Figure 8c and Figure 8d show the recommended circuit board layout for the REFH/REFL bypass capacitors. Note that in Figure 8c, every pin of the interdigitated capacitor (C1) is connected since the pins are not internally connected in some vendors' capacitors. In Figure 8d the REFH and

Figure 8b. Alternative REFH/REFL Bypass Circuit

REFL pins are connected by short jumpers in an internal layer. To minimize the inductance of these jumpers they can be placed in a small hole in the GND plane on the second board layer.

Figure 8c. Recommended Layout for the REFH/REFL Bypass Circuit in Figure 8a

Figure 8d. Recommended Layout for the REFH/REFL Bypass Circuit in Figure 8b

Figure 9. Using an External 1.25V Reference

Encode Inputs

The signal quality of the encode inputs strongly affects the A/D noise performance. The encode inputs should be treated as analog signals – do not route them next to digital traces on the circuit board. There are two modes of operation for the encode inputs: the differential encode mode (Figure 10), and the single-ended encode mode (Figure 11).

The differential encode mode is recommended for sinusoidal, PECL, or LVDS encode inputs (Figure 12 and Figure 13). The encode inputs are internally biased to 1.2V through 10k Ω equivalent resistance. The encode inputs can be taken above V_{DD} (up to 3.6V), and the common mode range is from 1.1V to 1.6V. In the differential encode

APPLICATIONS INFORMATION

Figure 10. Equivalent Encode Input Circuit for Differential Encode Mode

Figure 11. Equivalent Encode Input Circuit for Single-Ended Encode Mode

Figure 12. Sinusoidal Encode Drive

Figure 13. PECL or LVDS Encode Drive

mode, ENC^- should stay at least 200mV above ground to avoid falsely triggering the single ended encode mode. For good jitter performance ENC^+ and ENC^- should have fast rise and fall times.

The single-ended encode mode should be used with CMOS encode inputs. To select this mode, ENC^- is connected to ground and ENC^+ is driven with a square wave encode input. ENC^+ can be taken above V_{DD} (up to 3.6V) so 1.8V to 3.3V CMOS logic levels can be used. The ENC^+ threshold is 0.9V. For good jitter performance ENC^+ should have fast rise and fall times.

If the encode signal is turned off or drops below approximately 500kHz, the A/D enters nap mode.

Clock Duty Cycle Stabilizer

For good performance the encode signal should have a 50% ($\pm 5\%$) duty cycle. If the optional clock duty cycle stabilizer circuit is enabled, the encode duty cycle can vary from 10% to 90% and the duty cycle stabilizer will maintain a constant 50% internal duty cycle. If the encode signal changes frequency, the duty cycle stabilizer circuit requires one hundred clock cycles to lock onto the input clock. The duty cycle stabilizer is enabled by mode control register A2 (serial programming mode), or by $\overline{\text{CS}}$ (parallel programming mode).

For applications where the sample rate needs to be changed quickly, the clock duty cycle stabilizer can be disabled. If the duty cycle stabilizer is disabled, care should be taken to make the sampling clock have a 50% ($\pm 5\%$) duty cycle. The duty cycle stabilizer should not be used below 2Msps.

DIGITAL OUTPUTS

Digital Output Modes

The LTC2270 can operate in three digital output modes: full rate CMOS, double data rate CMOS (to halve the number of output lines), or double data rate LVDS (to reduce digital noise in the system.) The output mode is set by mode control register A3 (serial programming mode), or by SCK (parallel programming mode). Note that double data rate CMOS cannot be selected in the parallel programming mode.

APPLICATIONS INFORMATION

Full Rate CMOS Mode

In full rate CMOS mode the data outputs (D1_0 to D1_15 and D2_0 to D2_15), overflow (OF2, OF1), and the data output clocks (CLKOUT⁺, CLKOUT⁻) have CMOS output levels. The outputs are powered by OV_{DD} and OGND which are isolated from the A/D core power and ground. OV_{DD} can range from 1.1V to 1.9V, allowing 1.2V through 1.8V CMOS logic outputs.

For good performance the digital outputs should drive minimal capacitive loads. If the load capacitance is larger than 10pF a digital buffer should be used.

Double Data Rate CMOS Mode

In Double Data Rate CMOS mode, two data bits are multiplexed and output on each data pin. This reduces the number of digital lines by seventeen, simplifying board routing and reducing the number of input pins needed to receive the data. The data outputs (D1_0_1, D1_2_3, D1_4_5, D1_6_7, D1_8_9, D1_10_11, D1_12_13, D1_14_15, D2_0_1, D2_2_3, D2_4_5, D2_6_7, D2_8_9, D2_10_11, D2_12_13, D2_14_15), overflow (OF2_1), and the data output clocks (CLKOUT⁺, CLKOUT⁻) have CMOS output levels. The outputs are powered by OV_{DD} and OGND which are isolated from the A/D core power and ground. OV_{DD} can range from 1.1V to 1.9V, allowing 1.2V through 1.8V CMOS logic outputs. Note that the overflow for both ADC channels is multiplexed onto the OF2_1 pin.

For good performance the digital outputs should drive minimal capacitive loads. If the load capacitance is larger than 10pF a digital buffer should be used.

Double Data Rate LVDS Mode

In double data rate LVDS mode, two data bits are multiplexed and output on each differential output pair. There are eight LVDS output pairs per ADC channel (D1_0_1⁺/D1_0_1⁻ through D1_14_15⁺/D1_14_15⁻ and D2_0_1⁺/D2_0_1⁻ through D2_14_15⁺/D2_14_15⁻) for the digital output data. Overflow (OF2_1⁺/OF2_1⁻) and the data

output clock (CLKOUT⁺/CLKOUT⁻) each have an LVDS output pair. Note that the overflow for both ADC channels is multiplexed onto the OF2_1⁺/OF2_1⁻ output pair.

By default the outputs are standard LVDS levels: 3.5mA output current and a 1.25V output common mode voltage. An external 100Ω differential termination resistor is required for each LVDS output pair. The termination resistors should be located as close as possible to the LVDS receiver.

The outputs are powered by OV_{DD} and OGND which are isolated from the A/D core power and ground. In LVDS mode, OV_{DD} must be 1.8V.

Programmable LVDS Output Current

In LVDS mode, the default output driver current is 3.5mA. This current can be adjusted by serially programming mode control register A3. Available current levels are 1.75mA, 2.1mA, 2.5mA, 3mA, 3.5mA, 4mA and 4.5mA.

Optional LVDS Driver Internal Termination

In most cases using just an external 100Ω termination resistor will give excellent LVDS signal integrity. In addition, an optional internal 100Ω termination resistor can be enabled by serially programming mode control register A3. The internal termination helps absorb any reflections caused by imperfect termination at the receiver. When the internal termination is enabled, the output driver current is doubled to maintain the same output voltage swing.

Overflow Bit

The overflow output bit outputs a logic high when the analog input is either over-ranged or under-ranged. The overflow bit has the same pipeline latency as the data bits. In Full-Rate CMOS mode each ADC channel has its own overflow pin (OF1 for channel 1, OF2 for channel 2). In DDR CMOS or DDR LVDS mode the overflow for both ADC channels is multiplexed onto the OF2_1 output.

APPLICATIONS INFORMATION

Phase Shifting the Output Clock

In Full Rate CMOS mode the data output bits normally change at the same time as the falling edge of CLKOUT⁺, so the rising edge of CLKOUT⁺ can be used to latch the output data. In Double Data Rate CMOS and LVDS modes the data output bits normally change at the same time as the falling and rising edges of CLKOUT⁺. To allow adequate set-up and hold time when latching the data, the CLKOUT⁺ signal may need to be phase shifted relative to the data output bits. Most FPGAs have this feature; this is generally the best place to adjust the timing.

The LTC2270 can also phase shift the CLKOUT⁺/CLKOUT⁻ signals by serially programming mode control register A2. The output clock can be shifted by 0°, 45°, 90°, or 135°. To use the phase shifting feature the clock duty cycle stabilizer must be turned on. Another control register bit can invert the polarity of CLKOUT⁺ and CLKOUT⁻, independently of the phase shift. The combination of these two features enables phase shifts of 45° up to 315° (Figure 14).

DATA FORMAT

Table 1 shows the relationship between the analog input voltage, the digital data output bits and the overflow bit. By default the output data format is offset binary. The 2's complement format can be selected by serially programming mode control register A4.

Table 1. Output Codes vs Input Voltage

| $A_{IN^+} - A_{IN^-}$ (2V Range) | OF | D15-D0 (OFFSET BINARY) | D15-D0 (2's COMPLEMENT) |
|-------------------------------------|----|---------------------------|----------------------------|

Figure 14. Phase Shifting CLKOUT

APPLICATIONS INFORMATION

Digital Output Randomizer

Interference from the A/D digital outputs is sometimes unavoidable. Digital interference may be from capacitive or inductive coupling or coupling through the ground plane. Even a tiny coupling factor can cause unwanted tones in the ADC output spectrum. By randomizing the digital output before it is transmitted off chip, these unwanted tones can be randomized which reduces the unwanted tone amplitude.

The digital output is randomized by applying an exclusive-OR logic operation between the LSB and all other data output bits. To decode, the reverse operation is applied – an exclusive-OR operation is applied between the LSB and all other bits. The LSB, OF and CLKOUT outputs are not affected. The output randomizer is enabled by serially programming mode control register A4.

Alternate Bit Polarity

Another feature that reduces digital feedback on the circuit board is the alternate bit polarity mode. When this mode is enabled, all of the odd bits (D1, D3, D5, D7, D9, D11, D13, D15) are inverted before the output buffers. The even bits (D0, D2, D4, D6, D8, D10, D12, D14), OF and CLKOUT are not affected. This can reduce digital currents in the circuit board ground plane and reduce digital noise, particularly for very small analog input signals.

When there is a very small signal at the input of the A/D that is centered around mid-scale, the digital outputs toggle between mostly 1's and mostly 0's. This simultaneous switching of most of the bits will cause large currents in the ground plane. By inverting every other bit, the alternate bit polarity mode makes half of the bits transition high while half of the bits transition low. This cancels current flow in the ground plane, reducing the digital noise.

The digital output is decoded at the receiver by inverting the odd bits (D1, D3, D5, D7, D9, D11, D13, D15.) The alternate bit polarity mode is independent of the digital output randomizer – either, both or neither function can be on at the same time. The alternate bit polarity mode is enabled by serially programming mode control register A4.

Figure 15. Functional Equivalent of Digital Output Randomizer

Figure 16. Decoding a Randomized Digital Output Signal

APPLICATIONS INFORMATION

Digital Output Test Patterns

To allow in-circuit testing of the digital interface to the A/D, there are several test modes that force the A/D data outputs (OF, D15-D0) to known values:

All 1s: All outputs are 1

All 0s: All outputs are 0

Alternating: Outputs change from all 1s to all 0s on alternating samples.

Checkerboard: Outputs change from 101010101010101 to 010101010101010 on alternating samples.

The digital output test patterns are enabled by serially programming mode control register A4. When enabled, the Test Patterns override all other formatting modes: 2's complement, randomizer, alternate bit polarity.

Output Disable

The digital outputs may be disabled by serially programming mode control register A3. All digital outputs including OF and CLKOUT are disabled. The high-impedance disabled state is intended for in-circuit testing or long periods of inactivity – it is too slow to multiplex a data bus between multiple converters at full speed. When the outputs are disabled both channels should be put into either sleep or nap mode.

Sleep and Nap Modes

The A/D may be placed in sleep or nap modes to conserve power. In sleep mode the entire device is powered down, resulting in 0.5mW power consumption. The amount of time required to recover from sleep mode depends on the size of the bypass capacitors on V_{REF} , REFH, and REFL. For the suggested values in Fig. 8, the A/D will stabilize after 2ms.

In nap mode the A/D core is powered down while the internal reference circuits stay active, allowing faster wakeup than from sleep mode. Recovering from nap mode requires at least 100 clock cycles. If the application demands very accurate DC settling then an additional 50 μ s should be

allowed so the on-chip references can settle from the slight temperature shift caused by the change in supply current as the A/D leaves nap mode. Either channel 2 or both channels can be placed in nap mode; it is not possible to have channel 1 in nap mode and channel 2 operating normally.

Sleep mode and nap mode are enabled by mode control register A1 (serial programming mode), or by SDI and SDO (parallel programming mode).

DEVICE PROGRAMMING MODES

The operating modes of the LTC2270 can be programmed by either a parallel interface or a simple serial interface. The serial interface has more flexibility and can program all available modes. The parallel interface is more limited and can only program some of the more commonly used modes.

Parallel Programming Mode

To use the parallel programming mode, PAR/SER should be tied to V_{DD} . The CS, SCK, SDI and SDO pins are binary logic inputs that set certain operating modes. These pins can be tied to V_{DD} or ground, or driven by 1.8V, 2.5V, or 3.3V CMOS logic. When used as an input, SDO should be driven through a 1k series resistor. Table 2 shows the modes set by CS, SCK, SDI and SDO.

Table 2. Parallel Programming Mode Control Bits (PAR/SER = V_{DD})

| PIN | DESCRIPTION |
|---------|---|
| CS | Clock Duty Cycle Stabilizer Control Bit 0 = Clock Duty Cycle Stabilizer Off 1 = Clock Duty Cycle Stabilizer On |
| SCK | Digital Output Mode Control Bit 0 = Full-Rate CMOS Output Mode 1 = Double Data Rate LVDS Output Mode (3.5mA LVDS Current, Internal Termination Off) |
| SDI/SDO | Power Down Control Bit 00 = Normal Operation 01 = Channel 1 in Normal Operation, Channel 2 in Nap Mode 10 = Channel 1 and Channel 2 in Nap Mode 11 = Sleep Mode (Entire Device Powered Down) |

APPLICATIONS INFORMATION

Serial Programming Mode

To use the serial programming mode, PAR/SER should be tied to ground. The CS, SCK, SDI and SDO pins become a serial interface that program the A/D mode control registers. Data is written to a register with a 16-bit serial word. Data can also be read back from a register to verify its contents.

Serial data transfer starts when CS is taken low. The data on the SDI pin is latched at the first 16 rising edges of SCK. Any SCK rising edges after the first 16 are ignored. The data transfer ends when CS is taken high again.

The first bit of the 16-bit input word is the R/W bit. The next seven bits are the address of the register (A6:A0). The final eight bits are the register data (D7:D0).

If the R/W bit is low, the serial data (D7:D0) will be written to the register set by the address bits (A6:A0). If the R/W bit is high, data in the register set by the address bits (A6:A0) will be read back on the SDO pin (see the timing diagrams). During a read back command the register is not updated and data on SDI is ignored.

The SDO pin is an open drain output that pulls to ground with a 200Ω impedance. If register data is read back through SDO, an external 2k pull-up resistor is required. If serial data is only written and read back is not needed, then SDO can be left floating and no pull-up resistor is needed.

Table 3 shows a map of the mode control registers.

Software Reset

If serial programming is used, the mode control registers should be programmed as soon as possible after the power supplies turn on and are stable. The first serial command must be a software reset which will reset all register data bits to logic 0. To perform a software reset, bit D7 in the

reset register is written with a logic 1. After the reset SPI write command is complete, bit D7 is automatically set back to zero.

GROUNDING AND BYPASSING

The LTC2270 requires a printed circuit board with a clean unbroken ground plane. A multilayer board with an internal ground plane in the first layer beneath the ADC is recommended. Layout for the printed circuit board should ensure that digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track or underneath the ADC.

High quality ceramic bypass capacitors should be used at the V_{DD}, OV_{DD}, V_{CM}, V_{REF}, REFH and REFL pins. Bypass capacitors must be located as close to the pins as possible. Size 0402 ceramic capacitors are recommended. The traces connecting the pins and bypass capacitors must be kept short and should be made as wide as possible.

Of particular importance is the capacitor between REFH and REFL. This capacitor should be on the same side of the circuit board as the A/D, and as close to the device as possible.

The analog inputs, encode signals, and digital outputs should not be routed next to each other. Ground fill and grounded vias should be used as barriers to isolate these signals from each other.

HEAT TRANSFER

Most of the heat generated by the LTC2270 is transferred from the die through the bottom-side exposed pad and package leads onto the printed circuit board. For good electrical and thermal performance, the exposed pad must be soldered to a large grounded pad on the PC board. This pad should be connected to the internal ground planes by an array of vias.

APPLICATIONS INFORMATION

Table 3. Serial Programming Mode Register Map (PAR/SER = GND)

REGISTER A0: RESET REGISTER (ADDRESS 00h)

| D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|-------|----|----|----|----|----|----|----|
| RESET | X | X | X | X | X | X | X |

Bit 7 **RESET** Software Reset Bit

0 = Not Used

1 = Software Reset. All Mode Control Registers Are Reset to 00h. The ADC Is Momentarily Placed in SLEEP Mode. This Bit Is Automatically Set Back to Zero at the End of the SPI Write Command. The Reset Register Is Write-Only. Data Read Back from the Reset Register Will Be Random.

Bits 6-0 Unused, Don't Care Bits.

REGISTER A1: POWER-DOWN REGISTER (ADDRESS 01h)

| D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|----|----|----|----|----|----|---------|---------|
| X | X | X | X | X | X | PWROFF1 | PWROFF0 |

Bits 7-2 Unused, Don't Care Bits.

Bits 1-0 **PWROFF1:PWROFF0** Power Down Control Bits

00 = Normal Operation

01 = Channel 1 in Normal Operation, Channel 2 in Nap Mode

10 = Channel 1 and Channel 2 in Nap Mode

11 = Sleep Mode

REGISTER A2: TIMING REGISTER (ADDRESS 02h)

| D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|----|----|----|----|--------|-----------|-----------|-----|
| X | X | X | X | CLKINV | CLKPHASE1 | CLKPHASE0 | DCS |

Bits 7-4 Unused, Don't Care Bits.

Bit 3 **CLKINV** Output Clock Invert Bit

0 = Normal CLKOUT Polarity (As Shown in the Timing Diagrams)

1 = Inverted CLKOUT Polarity

Bits 2-1 **CLKPHASE1:CLKPHASE0** Output Clock Phase Delay Bits

00 = No CLKOUT Delay (As Shown in the Timing Diagrams)

01 = CLKOUT⁺/CLKOUT⁻ Delayed by 45° (Clock Period • 1/8)

10 = CLKOUT⁺/CLKOUT⁻ Delayed by 90° (Clock Period • 1/4)

11 = CLKOUT⁺/CLKOUT⁻ Delayed by 135° (Clock Period • 3/8)

Note: If the CLKOUT Phase Delay Feature Is Used, the Clock Duty Cycle Stabilizer Must Also Be Turned On

Bit 0 **DCS** Clock Duty Cycle Stabilizer Bit

0 = Clock Duty Cycle Stabilizer Off

1 = Clock Duty Cycle Stabilizer On

| LTC5584 | 30MHz to 1.4GHz Wideband I/Q Demodulator | I/Q Demodulation Bandwidth >530MHz, 31dBm IIP3, IIP2 Adjustable to >80dBm, DC Offset Adjustable to Zero, 45dB Image Rejection |
| LTC5585 | 700MHz to 3GHz Wideband I/Q Demodulator | I/Q Demodulation Bandwidth >530MHz, 25.7dBm IIP3, IIP2 Adjustable to >80dBm, DC Offset Adjustable to Zero, 43dB Image Rejection |

Данный компонент на территории Российской Федерации**Вы можете приобрести в компании MosChip.**

Для оперативного оформления запроса Вам необходимо перейти по данной ссылке:

<http://moschip.ru/get-element>

Вы можете разместить у нас заказ для любого Вашего проекта, будь то серийное производство или разработка единичного прибора.

В нашем ассортименте представлены ведущие мировые производители активных и пассивных электронных компонентов.

Нашей специализацией является поставка электронной компонентной базы двойного назначения, продукции таких производителей как XILINX, Intel (ex.ALTERA), Vicor, Microchip, Texas Instruments, Analog Devices, Mini-Circuits, Amphenol, Glenair.

Сотрудничество с глобальными дистрибуторами электронных компонентов, предоставляет возможность заказывать и получать с международных складов практически любой перечень компонентов в оптимальные для Вас сроки.

На всех этапах разработки и производства наши партнеры могут получить квалифицированную поддержку опытных инженеров.

Система менеджмента качества компании отвечает требованиям в соответствии с ГОСТ Р ИСО 9001, ГОСТ Р В 0015-002 и ЭС РД 009
